It is generally considered that if bleeding ceases and a pregnancy complicated by threatened abortion continues, the end-result will be good, but the observation that the hemoglobin and red blood cell levels in the baby's cord blood at birth were higher than normal when there was a history of threatened abortion suggested that the oxygen supply of these fetuses had been abnormal. The authors present data on oxygen and hemoglobin levels and red blood cell counts in the cord blood of the fetus from pregnancies complicated by threatened abortion. A study of the outcome of pregnancy in cases of threatened abortion in Aberdeen Hospital cases indicates that the danger to the fetus is not over when the bleeding ceases. Of 155 women leaving hospital after apparently successful treatment of threatened abortion, 19% subsequently aborted. For those delivered after the 28th week, the prematurity, obstetric death, and antepartum hemorrhage rates were approximately three times as great as the average for all booked patients and the incidence of fetal abnormality about twice as great. The excessive fetal death rate was associated especially with prematurity and antepartum hemorrhage. The high proportion of very small babies was explained largely by the high incidence of premature labor, but there was also a suggestion that fetal growth was slightly depressed after threatened abortion. Neither the raised incidence of fetal abnormalties nor the type thereof was clearly related to the time of onset of bleeding. It is difficult to say whether these findings can be explained by a persisting or recurrent maternal defect that caused first threatened abortion and later antepartum hemorrhage and premature labor or whether damage to the deciduoplacental site at the time of the initial bleeding was itself sufficient to cause permanent impairment of function. Possibly either or both mechanisms may be present in any given case.

PEDIATRICS

Freeze-Dried B. C. G. Vaccination of Newborn Infants with a British Vaccine. M. I. Griffiths and W. Gaisford. Brit. M. J. 2:565-568 (Sept. 8) 1956 [London, England].

The Danish BCG vaccine has proved uniformly satisfactory for use in appropriate dosage in newborn infants. It suffers, however, from the defects inherent in any living liquid vaccine and it produces complications of a minor, but nevertheless undesirable, nature in a small proportion of cases. An efficient dried vaccine would offer so many advantages over a liquid preparation that it would become the standard form for universal use. The difficulties encountered in the preparation of freeze-dried vaccines have been in conserving an adequate number of viable organisms that will remain viable and in reconstituting the dried mass to produce a uniform suspension with minimal clumping. For the past 18 months the authors have been using a freeze-dried vaccine prepared by the method described by Ungar, Farmer, and Muggleton. They have vaccinated 1,100 newborn infants with various batches of this vaccine. A batch containing approximately 10,000 viable bacilli per inoculating dose was soon found to be antigenically inadequate and was discontinued. Another batch containing approximately 1 million viable organisms per inoculating dose was slightly more potent than the Danish liquid BCG in allergy production, but as it produced large lesions at the site of inoculation and glandular complications (5% of enlarged axillary nodes and 0.6% of nodal abscess formation) the authors consider that it is a little too potent for routine use. Two other batches containing 110,000-130,000 viable organisms per inoculating dose, although only very slightly less antigenic than the Danish vaccine, have produced no complications to date and appear to provide the optimal dose.

Agammaglobulinemia in Two Brothers. J. Haarstad. Acta med. scandinav. 155:125-129 (No. 2) 1956 (In English) [Stockholm, Sweden].

The author describes a typical case of agammaglobulinemia in two brothers. The two patients, aged 9 and 4 years, the only children of parents with normal serum gamma globulin levels as revealed by paper electrophoresis, had been ill almost all their lives. Both had a history of abnormal susceptibility to infections, recurrent periods of rises in temperature without apparent cause, pulmonary symptoms, dystrophy, slight increase in weight, thin and slimy feces, and delayed static motor development. The absence of gamma globulins in the patients' serums was revealed by electrophoresis. The older boy was admitted to hospital for the treatment of an acute attack of pneumonia that responded to the administration of streptomycin and penicillin; these drugs, however, had no effect when used for prophylactic treatment. The effect of treatment with 0.1 gm. of gamma globulin per kilogram of body weight was uncertain in the older patient, but weekly injections of the same dose of gamma globulin had a good prophylactic effect in the younger patient.

Hibernation in Poliomyelitis. F. C. Matera, A. R. Alvarez, B. Mesz and others. Arch. argent. pediat. 27:58-64 (Jan.-Feb.) 1956 (In Spanish) [Buenos Aires, Argentina].

Forty patients from 3 months to 14 years of age with poliomyelitis were treated by hibernation with the aid of chlorpromazine and promethazine. The patients were acutely ill with encephalitis, bulboencephalitis, bulboencephalospinal and ascending paralysis, and with intractable fever and severe metabolic disorders. They were given 1 mg. of chlorpromazine per kilogram of body weight intramuscularly one hour before the start of the treatment, as a test for sensitivity. Children below 3 years of age were given the drug intramuscularly in total daily doses of between 3 and 25 mg. per kilogram of body weight. The solution for intramuscular injection contained equal parts of the drug in the daily dose to be given plus 20 units of hyaluronidase for each cubic centimeter of the solution. The injections were given at intervals of 3 or 4 hours during the critical period, after which the intervals varied from 8 to 12 hours. Children between 3 and 14 years of age were given the drug intravenously in daily doses that varied between 2 and 8 mg. per kilogram of body weight. The total daily dose was prepared in a 5% dextrose solution and was given by infusion at an extremely slow rate. Warming of the patients (dehibernation) was started as soon as the acute symptoms were controlled. During this period the patient was given androgens, ascorbic acid, and corticoadrenal preparations. The symptoms rarely reappeared after the warming of the patient was started, but if they did the treatment was repeated. Simultaneously with hibernation, the patients were treated for their clinical condition. Hibernation reached a low degree in all patients, although large doses of the drugs had to be used at times. Duration of hibernation varied from four to nine days. Fever was lowered in 32 of the 40 patients. Five of the eight patients in whom fever persisted died. The treatment gave satisfactory results in 28 patients. In all, 12 patients died: 5 of the 8 with intractable fever, 3 out of the 15 who had tracheotomy, 3 out of 6 with edema, and one who died from respiratory paralysis during intravenous administration of the hibernating drugs. The authors conclude that hibernation has a sedative, hypnotic, hypothermic, and muscle-relaxing action by means of which the cellular metabolism is improved, the progression of specific lesions is prevented, and the reversibility of the lesions is assisted. This is a preliminary report.

A Distinctive Type of Biliary Cirrhosis of the Liver Associated with Cystic Fibrosis of the Pancreas: Recognition Through Signs of Portal Hypertension. P. A. di Sant'Agnese and W. A. Blanc. Pediatrics 18:387-409 (Sept.) 1956 [Springfield, Ill.].

Four boys and three girls between the ages of 4 and 10 years with cystic fibrosis of the pancreas and clinically manifest cirrhosis of the liver were studied. All seven had pulmonary disease characterized by generalized obstructive emphysema and chronic bronchopneumonia in varying degrees of severity. The increase in concentration of chloride and sodium in the sweat, characteristic of patients with cystic fibrosis, was present in all. Five patients had pancreatic deficiency as shown by the absence of trypsin in the duodenal contents. Tryptic activity and viscosity of the duodenal contents were low in the two remaining patients. Hepatosplenomegaly was present in all patients, but none had jaundice. The lack of consistency in the results of so-called liver-function tests was notable, since in some of the patients they were normal even when the hepatic process, especially the portal hypertension, was quite advanced. Biopsy of the liver in five patients, obtained at laparotomy, revealed cirrhosis. In four of these the venous pressure in the portal system was found to be markedly elevated, and surgical shunting procedures were performed to relieve the increased tension. Liver biopsy was not performed in two patients, but all seven presented clinical evidence of portal hypertension, although the symptoms of hypersplenism, gastrointestinal bleeding, or ascites were much more severe in the five patients who were operated on. Two of the children died of progressive pulmonary disease and a third from uncontrollable gastrointestinal hemorrhage. Four patients are alive; one of these had no recurrence of gastrointestinal bleeding within three years after splenectomy and a splenorenal vein shunt, but her pulmonary status had deteriorated; one patient was doing well after a portacaval shunt; in one patient the liver involvement was less serious than the pulmonary condition, and one patient was doing well but hypersplenism had recently appeared.

The name multilobar biliary cirrhosis with concretions was given to the advanced hepatic process observed in these patients, to emphasize the distinctive character of the cirrhosis in cystic fibrosis of the pancreas. Stress is laid on the fact that symptoms appear only when portal hypertension develops, leading to ascites, hypersplenism, or gastrointestinal bleeding. In only 7 of the 325 patients with cystic fibrosis of the pancreas who were seen at the Babies' Hospital in New York between 1935 and 1955 did the disease progress to this syndrome. While the total number affected by this condition, therefore, is not large, a survey of the diagnostic files shows that it accounts in this hospital for one-third of the pediatric patients with cirrhosis of the liver from all causes and for a much greater proportion of the children with portal hypertension secondary to hepatic fibrosis. An operative shunting procedure may be needed, as gastrointestinal bleeding may be the greatest immediate risk to the patient. The hepatic area thus must be added to the ones frequently involved in cystic fibrosis of the pancreas, and this disease must be included among the important causes of portal hypertension secondary to cirrhosis of the liver in children.

Patent Ductus Arteriosus with Reversal of Flow: Clinical Study of Ten Children. R. C. Anderson, P. Adams Jr. and R. L. Varco. Pediatrics 18:410-423 (Sept.) 1956 [Springfield, Ill.].

Eight girls and two boys between the ages of 16 months and 15 years with patent ductus arteriosus with reversal of flow (pulmonary artery to aorta) are reported on. Cyanosis of the nailbeds, often greater in the toes, was present in all. Exertional dyspnea occurred early. Murmurs were of no diagnostic value, but an accentuated pulmonic second sound was uniformly present. Right ventricular preponderance was revealed by the electrocardiogram in all patients. The size of the cardiac shadow varied in the roentgenograms, but there was usually prominence of the pulmonary artery segment. Six patients showed evidence of bidirectional shunts and one showed only a reversed shunt, while the data were insufficient for the determination of this point in the remaining three. Three patients were operated on, with a satisfactory result in one, a 16-month-old infant, in whom a biopsy of the lung taken in the course of the operation revealed only minimal pulmonary arterial changes. Forty-five cases of patent ductus arteriosus with reversal of flow were collected from the literature. Most of them were in adults. Twenty-two patients were operated on, with good results in four, three of whom were children.

Patent ductus arteriosus with reversed flow must be differentiated from interventricular septal defect (Eisenmenger complex in particular), idiopathic primary pulmonary hypertension, interatrial septal defect, mitral stenosis, tetralogy of Fallot, chronic pulmonary disease, atrioventricular canal, truncus arteriosus, and single ventricle. The safest and simplest diagnostic test is the determination of oxygen saturation of samples of blood obtained simultaneously from the right brachial and femoral arteries. Angiocardiography and cardiac catheterization also provided helpful information. The diagnosis of reverse patent ductus arteriosus is not difficult to make if the entity is kept in mind. Patent ductus arteriosus with reversal of flow can no longer be considered rare. Surgical treatment of the condition has been very disappointing, especially in adults. There is reason to believe that surgical intervention very early in life may arrest or reverse the development of pulmonary changes, which contribute largely to the high surgical mortality in the older age groups; surgical treatment may thus yield a higher salvage rate.

Endocardial Fibroelastosis in Infants Associated with Thrombosis and Calcification of Arteries and Myocardial Infarcts.

W. A Thomas, K. T. Lee, M. H. McGavran and E. R. Rabin. New England J. Med. 255:464-468 (Sept. 6) 1956 [Boston].

The autopsy protocols and microscopic sections from two infants who had died with myocardial infarcts resulting from advanced disease of the coronary arteries with calcification were studied in an effort to obtain some clues to the cause and pathogenesis of the disease. The material from these patients was also compared with that from 24 infants with uncomplicated endocardial fibroelastosis, 2 infants with the left coronary artery arising from the pulmonary artery, 1 infant with endocardial fibroelastosis complicated by mural thrombosis and myocardial infarcts without calcific arterial lesions, and 5 rabbits with myocardial infarcts resulting from thromboembolism. The two infants with calcific arterial disease and myocardial infarcts were found to have in addition endocardial fibroelastosis (characterized by fibroelastic thickening of the endocardium of the left ventricle and cardiac hypertrophy), an association not previously reported. Both of these diseases are uncommon, so it is unlikely that they were associated only by chance. Consideration of various ways in which the relation between the two diseases might be explained led to the conclusion that the most likely possibility was that the endocardial fibroelastosis was the underlying process and that the arterial disease and myocardial infarction resulted from thromboembolism.

Copper Deficiency in Infants: A Syndrome Characterized by Hypocupremia, Iron Deficiency Anemia, and Hypoproteinemia.

P. Sturgeon and C. Brubaker. A. M. A. J. Dis. Child. 92:254-265 (Sept.) 1956 [Chicago].

Sturgeon and Brubaker report on five infants in whom hypocupremia and hypoproteinemia were associated with iron deficiency anemia. At the time of diagnosis the patients ranged in age from 6½ to 9 months, with the exception of one, who was 2½ years old. All had in common a mild degree of edema and pallor. All had moderate anemia, microcytosis, and profound reduction in the concentrations of serum iron and serum copper. The total serum iron-binding capacity was not increased. The serum protein concentration was reduced in all cases. There was no laboratory evidence of renal or hepatic dysfunction. The authors believe that since these children had subsisted on a milk diet to the exclusion of practically all other foods, nutritional inadequacy may have played a part in producing the described syndrome. Preliminary therapeutic tests indicate that the various deficiencies can be corrected simultaneously with an improved diet and that, independently of the other deficiencies, the hypocupremia can be corrected with the oral administration of copper sulfate.

OTOLARYNGOLOGY

The Nasal Entrance in Relation to Nasal Function.

J. E. Poulin. J. Maine M. A. 47:274-275 (Sept.) 1956 [Portland, Maine].

Respiration is influenced to a great extent by the relative size of the nostril. The size and position of the anterior nares is determined by the character of the nasal tip and its surrounding anatomic structures. A deflection of the air current by a collapsed, twisted, or depressed nasal tip can in turn influence the size and position of the nasal entrance and in so doing affect the nasal physiology. The number of nasal tip deformities that are congenital in origin is small in comparison to the number produced by nasal injuries. Many of the injuries occur among children in infancy and early childhood and go unrecognized. A trivial blow on a child's nose resulting from a fall will often displace the tip of the cartilage in its septum. These accidents are frequently disregarded by the parents, and the unfortunate child has a displaced tip cartilage that becomes worse as time goes on. The incidence of neglected nasal injuries in the adult male is much greater than it should be. It is especially common among boys who participate in dangerous sports such as hockey, basketball, and football. Boys often accept a nasal injury as a part of the game and do nothing about it until they experience difficulty in breathing in later years. It is of the utmost importance to make certain that nasal trauma has not involved the tip of the nose, but if it has, proper steps should be taken to correct it as soon as possible.

Significance of Allergy in Persistent Respiratory Infection.

A. Dintenfass. A. M. A. Arch. Otolaryng. 64:171-177 (Sept.) 1956 [Chicago].

An attempt is made to demonstrate the close association and interdependence of respiratory-tract infection and allergy and the need for a thorough understanding of both allergic and surgical principles in order to obtain maximum therapeutic benefits. The association of allergy and infection affects all parts of the respiratory tract, producing diverse but characteristic pathological patterns in the nose, paranasal sinuses, Eustachian tubes, each of the anatomic divisions of the ear, and the bronchial tree. The underlying physiological and pathological processes are described. Efficient treatment is dependent upon adequate study of the allergic state. The offending allergens must be avoided or used in desensitization. Properly selected and timed surgical procedures in conjunction with allergic therapy provide maximum improvement and more permanent relief. Representative case histories illustrate the essential principles involved.

THERAPEUTICS

A Clinical and Bacteriologic Evaluation of Novobiocin in Seventy-Five Patients.

J. Z. Pearson, A. Somberg, I. Rosenthal and others. A. M. A. Arch. Int. Med. 98:273-283 (Sept.) 1956 [Chicago].

Novobiocin is a new antibiotic produced by a species of Streptomyces and discovered almost simultaneously by two independent groups. The authors used novobiocin in 75 patients, of whom 9 had either leukemia or polycythemia; they were followed with leukocyte counts, platelet counts, and hematocrit readings to see whether a drop in any of these indices would occur while novobiocin was being administered. Pretreatment cultures were obtained from all of the 66 patients with infections. Novobiocin (Albamycin, Cathomycin) was given orally, either in capsule form or in suspension, and the daily dose was 30 mg. per kilogram of body weight in children or 2 gm. in adults.

The response in infections with Micrococcus pyogenes var. aureus (staphylococci) was generally good except in cases where chronic tissue changes predisposed to continued infection. Improvement was noted in patients with pneumococcic and β-streptococcic infections, but the response was often not so prompt and the eradication of the organism not so consistent as in cases in which penicillin is used. No improvement was observed after administration of novobiocin to patients with infections caused by Enterococcus or Proteus organisms or in patients with actinomycosis or lung abscess. The median serum concentration of novobiocin after a standard dose was from 64 to 128 mcg. per milliliter, but there was wide variation. Untoward reactions were observed in 14 (18.7%) of the patients. Skin eruptions occurred in 12, eosinophilia in 5, leukopenia in 2, and jaundice in one. Eight of the patients were given a second course of novobiocin, and in five of these toxic signs or symptoms reappeared. Reactions to both proprietary forms of novobiocin (Albamycin, Cathomycin) were observed in two of the four patients to whom both were given. Strains of micrococci (staphylococci) resistant to novobiocin appeared in four patients treated for three months or longer.

Successful Treatment of Gonococcic Endocarditis with Erythromycin: Review of the Literature. D. S. Davis and M. J. Romansky. Am. J. Med. 21:473-480 (Sept.) 1956 [New York].

The authors report on a 23-year-old Negro woman in whom polyarticular arthritis developed during pregnancy five years after a probable primary gonorrheal infection. Under observation a systolic murmur first appeared and later became changing in character. A diastolic murmur also made a transient appearance. Coincident with the onset of murmurs, skin lesions of probable embolic nature appeared on the extremities. One of 10 cultures obtained during the initial period of observation yielded a growth of Neisseria gonorrhoeae, thereby confirming a diagnosis of gonococcic endocarditis. Specific therapy consisted of a total of 108 gm. of erythromycin administered orally and intravenously over a 32-day period. No growth was observed in nine blood cultures obtained during this course of treatment, and single blood cultures obtained on the fourth, sixth, and seventh days after cessation of therapy were negative. Marked objective and symptomatic improvement occurred during hospitalization lasting 53 days. Two and a half months later the patient was delivered of a healthy child without further untoward event. When last seen 10 months after the onset of her illness, the patient was still in excellent health. This is the first report of erythromycin therapy of gonococcic endocarditis.

Coumadin (Warfarin) Sodium: A New Anticoagulant. J. H. Nicholson and T. Leavitt Jr. New England J. Med. 255:491-501 (Sept. 13) 1956 [Boston].

Coumadin sodium is a monocoumarin compound, in contrast to Dicumarol, which is, as its name suggests, a dicoumarin compound. Unlike Dicumarol, cyclocumarol, Tromexan, and phenindione, Coumadin forms a stable sodium compound. The sodium derivative is soluble in water and forms stable solutions that can be administered parenterally. Its reported effectiveness by the oral, intravenous, intramuscular, or rectal route may reside in this property. The authors used this drug for acute thromboembolic episodes and prophylactic therapy in 100 patients in private practice and on the wards of the Lawrence General and Bon Secours hospitals. Coumadin sodium (Link's warfarin sodium) was given intravenously and orally. The induction of therapeutic hypoprothrombinemia (level of 35 to 10%) was relatively prompt. The use of heparin was limited to patients with pulmonary embolism, who received only about three or four doses of heparin. The initial dose averaged about 60 mg., and the daily maintenance dose by the continuous or intermittent method, based on daily prothrombin determinations, was about 10 mg. The maintenance dose, which was readily established, was generally consistent from day to day in the same patient. Fewer periods of "escape" from the therapeutic range occurred than with other anticoagulant drugs the authors had used.

Hemorrhagic phenomena, attributable to the drug, occurred in five patients (three had bleeding episodes and in two subcutaneous petechiae developed). Bleeding occurred only in patients who had undergone surgical treatment, and it subsided promptly after administration of phytonadione. No fatality was caused by the drug. These experiences and others reported in the literature indicate that Coumadin (warfarin) sodium is a more nearly ideal anticoagulant drug than any of its congeners now available. The drug deserves wide clinical application in thrombotic and thromboembolic disorders.

Effects of Tetrachlorethylene Without a Purge, Followed by Ferrous Sulfate in Ancylostomiasis. A. R. Pinto, F. C. Costa, L. V. deMeira and J. P. Viana. Am. J. Trop. Med. 5:739-741 (July) 1956 [Baltimore].

In 1954 it was demonstrated by Carr and co-workers in the Dominican Republic that tetrachlorethylene is more effective in the treatment of ancylostomiasis when it is not followed by a saline purgative. Pinto and associates tried this method in 165 patients in Portuguese West Africa. They found that the omission of the saline purge after treatment of hookworm infection with tetrachlorethylene increases the effectiveness of the drug, shortens the time of treatment, lowers its toxicity and cost, facilitates the administration of mass treatment, and improves the possibility of curing the disease.

PATHOLOGY

Immediate Passage of Tumor Cell Emboli Through the Liver and Kidney. I. Zeidman, W. J. Gamble and W. L. Clovis. Cancer Res. 16:814-818 (Sept.) 1956 [Chicago].

Experiments were made to ascertain whether or not tumor cell emboli could pass unarrested through the liver and kidney. The transplantable V$_2$ carcinoma was used in domestic rabbits and, in rats, transplantable Flexner-Jobling carcinoma, Murphy-Sturm lymphosarcoma, Lewis fibroma, and Lewis lymphoma. For transhepatic studies, tumor suspension was injected into the portal vein, and simultaneously blood was drawn from the vena cava just above the liver. The blood was then injected intravenously into a second animal. The development of tumors in the second animal indicated immediate transhepatic passage of tumor cell emboli in the first animal. In transrenal studies, tumor suspension was injected into the aorta above the kidneys, the blood was collected simultaneously from the renal vein, and this blood was injected intravenously into second normal animals. Immediate transhepatic and transrenal passage of tumor cell emboli occurred with all tumors used except the Flexner-Jobling. The incidences of such passage varied, being higher in tests with lymphoma cells. It is concluded that tumor cell emboli can pass unarrested through the circulation of both liver and kidney.

This report is one of a series dealing with the passage of tumor cell emboli through the circulatory bed of various organs. The problem was to determine whether or not tumor cells, circulating in the blood, may pass immediately through an organ, perhaps to lodge in a more distant organ. If so, this might account for some peculiarities in the distribution of metastases. For example, human cancers of the gastrointestinal tract occasionally metastasize to the lungs without producing visible liver metastases. Previously, it had been thought that this pattern of metastasis depends upon lymphatic and thoracic duct spread.

RADIOLOGY

Giant-Cell Tumors and Roentgen Treatment. S. Marzolla. Minerva med. 47:357-365 (Aug. 11) 1956 (In Italian) [Turin, Italy].

The author reports on nine patients with giant-cell tumor of bones who received radiological treatment. Five cases were controlled for many years. Very good results followed in all cases. The treatment gives good functional results and reduces to a minimum the danger of relapse. Doses must be moderate, because high doses may interfere with the rebuilding of the bone. The process of recovery is slow but certain. One sign of recovery not previously discussed in the literature is the diminution of transparency in the lacunar areas of the tumor before the deposition of calcium salts takes place. When recalcification starts, it proceeds slowly but steadily. A return to the normal architectural pattern of the bone cannot be expected; it will suffice to have a bone that is strong, solid, and resistant.

BOOK REVIEWS

Sports Injuries Manual for Trainers and Coaches. By Donald F. Featherstone. Foreword by R. Salisbury Woods, M.D., F.R.C.S. Cloth. $6. Pp. 132, with 24 illustrations. Philosophical Library, Inc., 15 E. 40th St., New York 16, 1956.

In his introduction, the author says that, although there may be some disagreement regarding the advisability of teaching the treatment of injuries to laymen, athletic trainers and coaches who are not medically qualified will, nevertheless, continue to treat most sports injuries. He has, therefore, designed this compact manual of reference to indicate to the layman not only correct management but also the limits beyond which the services of a physician are absolutely required. In point of fact, most physicians who are called on casually to treat sports injuries, although they may be familiar with the anatomic derangement and are able to offer effective first aid and immediate treatment, probably know less about the prevention and long-term management of these injuries than the experienced trainer or coach. Every general practitioner and surgeon would do well to familiarize himself with the principles involved in the total treatment of these injuries, since there are lessons to be learned here in regard to the shortening of periods of disability and the preservation of function that can be applied to the treatment of injuries from other causes.

The first part of the book is devoted to a concise, accurate, and easily comprehensible explanation of the basic anatomy and physiology of the human body. Particular emphasis is placed on the principal muscle groups and their actions. The second part is devoted to the basic knowledge and equipment the trainer must have to be prepared to aid the injured athlete. The third part discusses methods of prevention; and the fourth part, the treatment of strains, sprains, contusions, abrasions, and lacerations and skin infections. There is a short chapter on the more serious injuries, emphasizing immediate medical assistance; there is also a chapter on miscellaneous injuries. Since the author is English, the American reader will find some unfamiliar medicaments and methods of management recommended. Placing the blame for some muscle strains on the presence of systemic foci of infection seems a little outdated. Certainly most surgeons and orthopedists would not approve as adequate treatment for a Bennett fracture the strapping of the injured hand with elastic adhesive tape. Also, current thinking about the origin and spread of dermatophytosis does not favor the prophylactic use of foot baths containing a mild antiseptic solution. The illustrations are good but few in number. In general, the advice offered is practical, sensible, and based on wide experience. This book can be particularly recommended to physicians who attend high school and college athletes, as well as to the coaches and trainers for whom it is intended.

Corneal Grafts. Edited by B. W. Rycroft, O.B.E., M.D., D.O.M.S. With foreword by Sir Cecil Wakeby, K.B.E., C.B., LL.D Cloth. $13.50. Pp. 286; 13, with 155 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3; Butterworth & Co., Ltd., 88 Kingsway, London, W.C.2; 1367 Danforth Ave., Toronto 6, Ontario, Canada, 1955.

The chapters in this book on the anatomy and physiology of the cornea and the ultrastructure and chemical composition, with a discussion on the mucoids, salts, and metabolism, are all worthy of the reader's critical attention. Francois and Rabaey (1953) stated that the disappearance or the decrease of the mucoid substance of the stroma promotes vascularization. Neovascularization is still the mortal enemy of the corneal graft, and, when its causative factor or factors become known, a great step toward the elimination of corneal opacification will have been made. The pathology of corneal opacities is thoroughly described, with the aid of excellent photomicrographs. Paufique, the father of lamellar keratoplasty, states that the old prejudice against lamellar keratoplasty was based on the unavoidable opaque connective tissue formed behind the graft. He claims that this is now avoidable, due to the progress in asepses, advances in technique, and the use of antibiotics. He carefully describes and beautifully illustrates the technique of partial lamellar keratoplasty, using some of the instruments that are more often used in Europe than in the United States. He enumerates the postoperative complications of lamellar keratoplasty and their treatments now in vogue in Europe.

Some of the special methods as described by Sourdille, particularly the mushroom graft of Franceschetti with his apparatus, are given in detail. The general complications of corneal grafting are discussed by Tudor Thomas, who points out that gray streaks and haze of the donor cornea are likely to produce vascularization of the cornea and opacity. The use of citrated saline solution lessens the tendency of the iris to become adherent to the graft and is without danger, especially when the cornea shows only slight vascularization. Another important highlight of this chapter is the discussion of the treatment with antihistamines in the first two weeks. This is advocated to lessen the chances of any reaction to antigens contained in the corneal tissue. Frederick Ridley makes an important practical point in the preoperative temporary fitting of contact lenses. This procedure can be used to make a direct comparison between the apparent thickness of the cornea and the contact lens in the slit-lamp beam. This is of exceptional value where lamellar keratoplasty is contemplated. Dr. Marc Amsler introduces a valuable clinical procedure that is not generally done in the United States: a diagnostic puncture of the anterior chamber and the examination of the aqueous humor for its protein content and the enumeration of its cells. The presence of numerous cells indicates that inflammation of the uveal tract is still active, particularly if these cells are lymphocytes or even polymorphonuclear leukocytes. Dr. Amsler correctly states that, if perforating keratoplasties were always preceded by a careful study of the aqueous humor, they would present fewer disagreeable surprises for the surgeon, such as postoperative inflammations and secondary glaucoma. He also points out that keratography is useful for the study of asymmetrical and irregular curvatures of the cornea; it reveals the form that the graft takes once it is incorporated into the recipient cornea. Keratography offers an objective standard paralleling the subjective criterion of the visual acuity with the final operative result.

Under Methods of Preserving Tissue, Buschke (1951) states, "Since the stromal cells of the graft have to be alive at the time of its transplantation, storage methods entailing chemical preservation, freeze-drying, or quick-freezing in the absence of glycerol, merit no further consideration, since cells are known not to survive these treatments." The chapter on special instruments, corneal markers, and splints gives special attention to instruments used in Europe. Dr. Rycroft presents exhaustive reports on corneal grafts, as contained in the chapters by outstanding European pioneers, and has supplemented them with his own results and the reports of outstanding American ophthalmologists. The book is readable and amply illustrated. It should be in the library of any ophthalmologist who wants to keep up with what is happening in this field in Europe.

Currents in Biochemical Research 1956. Edited by David E. Green. Twenty-seven essays charting present course of biochemical research and considering intimate relationship of biochemistry to medicine, physiology, and biology. Cloth. $10. Pp. 697, with illustrations. Interscience Publishers, Inc., 250 Fifth Ave., New York 1; 88-90 Chancery Lane, London, W.C.2, England, 1956.

This volume records some of the work done by 32 authors in many important fields in biochemical research. The intent of the book, as stated by Dr. Green in the preface, was to give an over-all picture of the present status of significant problems in a particular field, to point out the present broad strategy used in attacking these problems, and then to speculate as to the paths most likely to be followed in future research. Much of the progress made on the many problems in biochemistry has been due to the development of new techniques in the isolation,

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

identification, and further characterization of biochemical substances. Such techniques include paper chromatography, spectrophotometry, electrophoresis, and the use of isotopes. In reading the various chapters, one is immediately impressed with the tremendous advances that have been made since the first volume was written 10 years ago. A glance at the titles of these essays suggests the vast amount of work that has been done in various phases of the enzyme study. A thorough reading of the book reveals even more the many related fields into which the study of enzymes has spread. At least eight of the essays are concerned directly with various general espects of enzyme chemistry, and most of the others devote a major portion of their material to more specific enzymes or enzyme systems. Included are such general topics as enzyme kinetics, enzyme complexes, induced enzyme formation, enzymes as reagents, enzymes in electron transfer, special problems in multiple enzyme systems, and the relationship between enzymes, coenzymes, nucleotides, and prosthetic groups.

Other relatively specific topics include a discussion on certain biochemical aspects of virus growth, bacterial fermentation, vitamin and growth factors, hormones, ribonucleic acids, porphyrin biosynthesis, sugar interconversion in nature, muscular and nerve activity, blood functions, and carcinogenesis. Subjects of a more general nature that are covered include problems of cellular biochemistry, biochemical problems in disease, chemical structure, and biochemical questions. Essays on various general aspects of protein structure and on the structure of insulin are also included. Each of the essays includes a bibliography. As shown by the varied subject matter presented, the field of biochemistry is broad and complex. It borders on genetics, cytology, physiology, and theroretical chemistry. Much of the material should be of interest to physicians.

Cytology of the Blood and Blood-Forming Organs. *By Marcel Bessis, Director of Research Laboratory, Centre national de transfusion sanguine, Paris, France. Translated by Eric Ponder. Cloth. $22. Pp. 629, with 405 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England, 1956.*

Since its inception, morphology has been the cornerstone of hematology, and hematology, which was once a rather drab subject, has expanded into physiopathology, immunology, and chemistry. Despite this, the cell has retained its preeminence due largely to the development of neomorphology. At one time, morphological studies were represented simply by the use of blood and bone marrow smears stained with one of the Romanowsky stains. In recent years, phase microscopy has allowed the observation of unstained material in the cell that is unseen with staining techniques. All manner of cytochemical methods have been developed for studying specific enzymes and other chemical materials in the cell. The motion picture technique, particularly with the use of time lapse has been developed to a high degree for the study of the actual life and death of a cell. Finally, electron microscopy has opened the door to the observation of materials within the cell consisting of only a few molecules. In all of these advances the author has pioneered, and, in fact, he has created in this book a new framework of morphological hematology. His remarkable phase microscopy pictures, his extraordinary electron microscopy, and his research with the aid of motion pictures have become well known to hematologists, particularly those with a knowledge of French. This book should serve to introduce his work to many English-speaking readers. Eric Ponder has done a fine job of translation. Dominating the book are the extraordinary electron and phase contrast photomicrographs of blood cells, which give a new dimension and insight into minute cellular structures. This English translation is an excellent reproduction of the original French treatise published in 1954; in addition, in many areas the text is greatly expanded, particularly in the fields of platelets, megakaryocytes, and electron microscopy. Orthodox morphology is by no means neglected, but neomorphology is here in full force and beauty. The book is excellently printed, the type is legible, and the photomicrographs are superb. Despite its high price, the book is a necessity for all those who work in the field of hematology.

Progress in Clinical Obstetrics and Gynaecology. *By T. L. T. Lewis, M.B., B. Chir., F.R.C.S., Obstetric Surgeon, Guy's Hospital, London, England. Cloth. $12. Pp. 594, with 90 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., Portman Sq., London, W.1, England, 1956.*

This book is designed to put in concise form the present knowledge of various conditions in the field of obstetrics and gynecology. Each chapter considers one problem. With such broad coverage, it is inevitable that the subjects are discussed in a condensed fashion. The author emphasizes things of practical significance at the expense of more basic studies of equal importance. He has also chosen to build up the data behind what are apparently his own conclusions. The British viewpoints and work are stressed, which makes it surprising to find, for example, such incomplete reports as those dealing with the anemias of pregnancy. The discussions of some of the malignant diseases are so condensed as to be grossly incomplete. There are some references at the end of each chapter; but these give altogether too much stress to the British literature, which in itself is incomplete, and almost none to the non-English-language literature. There is no reference to any studies by the author himself. The book does not, then, carry the authority of a reference book but is designed as a superficial but quick source of practical information for postgraduate teaching rather than as a book for graduate study. It is not an adequate source, as the author admits, for the specialist. It is well printed, with few typographical errors, on glossy paper. There is a moderate number of illustrations. The language is clear and concise. There is a good index. The book is recommended for the general practitioner doing work in obstetrics and gynecology, for the intern, and for those who need to understand the British approach to these practical problems. Subsequent volumes should limit the number of subjects to be considered and discuss them in greater detail.

The Premarital Consultation: A Manual for Physicians. *By Abraham Stone, M.D., Associate Clinical Professor of Preventive Medicine, New York University College of Medicine, and Lena Levine, M.D., Associate Medical Director, Margaret Sanger Research Bureau, New York. Cloth. $3. Pp. 90, with 11 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England, 1956.*

As is stated in the introduction to this book, premarital counseling is an extension of preventive medicine in the family unit. That it is important would seem to be an indisputable fact, yet, unfortunately, far too many physicians tend to shrug it off as something that has nothing to do with medicine. Inquirers are referred to psychologists or marriage counseling agencies that, even though admittedly providing excellent services, still cannot give the all-inclusive guidance the physician can and should offer. As the authors point out, this type of assistance is not beyond the scope of the general practitioner, despite the tendency to assign it to various specialty fields. After instructions on taking a premarital history and making necessary examinations are given in the manual, there is a chapter, which gives extensive guidance, dealing with interview of the couple. Interspersed throughout this chapter are questions and answers exchanged by the three participants. Information is provided on sexual adjustment, family planning and contraceptive methods, social and emotional factors in marriage, and the physiology of sex. This is followed by a brief and simplified discussion of genetics, with specific consideration of mental defects, epilepsy, and other rather common conditions. Especially helpful are sections in the appendix dealing with use of the vaginal diaphragm, marriage laws of the states, and birth control laws. This volume should be of interest and assistance to many physicians.

Accidental Poisoning in Childhood: A Reference-Guide to the Chemical Constituents of Common Household Substances, Together with Treatment Recommendations for Their Accidental Ingestion by Children. *Prepared by Committee on Accident Prevention, American Academy of Pediatrics, and written by Edward Press, M.D., M.P.H., Field Director, American Public Health Association. Cloth. $3. Pp. 131. American Academy of Pediatrics, 1801 Hinman Ave., Evanston, Ill.; published by Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill., 1956.*

In 1950, the American Academy of Pediatrics took official notice of the problems and hazards of poisoning by appointing a committee on accident prevention. Dr. Edward Press, working through this committee has now compiled a summary of the literature on the constitution of various household chemicals and methods of treatment. This booklet is divided into three main sections: Treatment Procedures, List of Toxic Substances and

Suggested Treatment, and Toxic Constituents of Household Products. For quick reference, these three sections have been set off from one another by pages of a different color. Since this booklet was compiled primarily to aid in treating children who have accidentally ingested household poisons, much of the recommended treatment is broken down into dosages for infants and young children. The author has also pointed out that the suggestions given are only a guide and "must not be used mechanically or one will slip into sloppy and ineffective 'slide-rule' medicine." Since it is almost physically impossible to include up-to-date information on the ingredients of all household products, the author has chosen to include a number of representative items. He has, however, included a list of references that may be consulted for additional information. Despite the fact that the scope of the book is limited to household poisons, its clarity of style and ease of reference provide an excellent guide for the physician who is called on to treat all types of accidental poisoning in children.

Surgery for General Practice. By Victor Richards, M.D., Professor of Surgery, Chairman of Department of Surgery, Stanford University School of Medicine, San Francisco, California. Cloth. $17.50. Pp. 947, with 476 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1956.

This textbook is a unique contribution. The author drew on his associates working in specialized fields in the same clinic, and the experiences cover a span of many years. The concept of treating the total patient rather than a diseased segment of his body is continually emphasized. The subjects discussed include local anesthesia, hemorrhage, shock, injury, surgical infection and chemotherapy, anticoagulants, burns, plastic surgery, tumors, surgical disorders of all parts of the body, hypertension, intractable pain, peripheral nerve surgery, and fractures. The limits of a textbook for general practitioners are difficult to define with accuracy. The underlying philosophy of the author in emphasizing the obligation to treat the whole patient is commendable. One may envision a simple problem initially, but it may rapidly become complicated. The author, therefore, has encompassed in this book methods of surgical treatment that will conduct patients safely through problems of changing complexity. The author has intentionally omitted a bibliography. This is not a book of operative techniques but one emphasizing the principles of surgery for the average physician. The tables, diagrams, and line drawings are effectively placed, precise, clear, and unusually illuminating. This book should be found high on the roster of timely and outstanding contributions. Every physician should have the fundamental surgical knowledge it presents.

Urology. By B. G. Clarke, M.S., M.D., F.A.C.S., Associate Professor of Urology, Tufts University School of Medicine, Boston, and Louis R. M. Del Guercio, M.D., Assistant Resident Surgeon, St. Vincent's Hospital, New York. Cloth. $6.50. Pp. 245, with 163 illustrations. Blakiston Division, McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C. 4, England, 1956.

This book is intended to give a brief presentation of the subject matter of special urologic interest to the undergraduate student and the general practitioner. It has a well-arranged short essential text complemented by a sufficient number of line drawings, diagrams, and pictures to partially replace lengthy detailed descriptions. As the authors remark, "For the leisurely reader, this material amplifies the text in much the same way as a series of short clinics on the commoner urogenital diseases." A selected list of references is provided with each chapter. Of the many textbooks on urology published in the past few years, this one is most suitable for the classroom work of the undergraduate student. There are some apparent omissions. Pneumaturia in a person with diabetes or pneumaturia associated with an enterovesical fistula is not mentioned. The discussion on the differential diagnosis of bladder tumors does not mention the necessity for recognizing irradiation granulomas, inflammatory areas, surrounding enterovesical fistulas, foreign bodies, or areas of encrusted cystitis. The importance of diabetes as a cause of renal papillary necrosis and persistent urinary infection is omitted. The character of the book suggests that the experience of the authors has been largely one of hospital care, with a paucity of reference to the more common genitourinary conditions that are seen in routine office practice.

Rosenau Preventive Medicine and Public Health. By Kenneth F. Maxcy, M.D., Dr.P.H. With 27 contributing authors. Eighth edition. Cloth. $15. Pp. 1465, with illustrations. Appleton-Century-Crofts, Inc., 35 W. 32nd St., New York 1, 1956.

This second revision of Rosenau's widely used textbook to be compiled by Dr. Maxcy appears five years after the previous edition. In that time Dr. Maxcy has retired from his chair in epidemiology. The words "public health" have replaced "hygiene" in the title. This was done to give better indication of the scope and purpose of the book, which remain unchanged. There has been no change in the list of contributors. The author states that about 44% of the text has been revised to bring it up-to-date. The length of the text has not been increased, but a more adequate index has been provided. The addition of such subjects as Coxsackie virus and adenovirus infections, epidemic nephritis, and West Nile encephalitis without increasing the size of the book has been accomplished by condensing some of the older material, omitting some of the graphs and tables, and in a few pages setting the lines closer together. The revision of the sections on tuberculosis and ionizing radiations was especially well done, and the latter is a matter of increasing interest. This book continues to be the outstanding work in its field. It contains much information that should be of value to the general practitioner and is an indispensable item in the library of the public health specialist.

The Morphology of Human Blood Cells. By L. W. Diggs, M.A., M.D., Professor of Medicine and Director of Medical Laboratories, University of Tennessee and City of Memphis Hospitals, Memphis; Dorothy Sturm, Instructor, Memphis Academy of Arts; and Ann Bell, B.A., Instructor in Medicine, University of Tennessee. Cloth, loose-leaf. $12. Pp. 181, with 54 illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1956.

This textbook, presented in atlas form, approaches the study of blood cells from the developmental and structual point of view rather than from that of the specific disease entity. The authors are to be commended on this emphasis, for a sound knowledge of the basic difference between normal and pathological cells is of great clinical value. The illustrations, in a separate section for easy reference, are of exceptional quality and are well integrated with the accompanying text. The use of commonly applied synonyms in addition to the standard terminology sponsored by the American Society of Clinical Pathologists and the American Medical Association, and the indexing of all terms, adds to the value of this reference book. The section on techniques and methods provides a useful review of these procedures, rather than a basic set of instructions, and describes some of the less common but occasionally needed stains. More could have been included on bone-marrow procedures. While the authors have prepared the book primarily for medical students and student technologists learning about blood cells for the first time, the text, perhaps due to its brevity, appears to require a substantial histological background. The book should be of value to the practicing physician who makes his own examination of blood smears.

The Recovery Room: Immediate Postoperative Management. By Max S. Sadove, M.D., Professor of Surgery (Anesth.) and Head, Division of Anesthesiology, University of Illinois College of Medicine and Research and Educational Hospitals, and James H. Cross, M.D., Clinical Assistant Professor in Surgery, University of Illinois College of Medicine, Chicago. With contributions by 24 authorities. Cloth. $12. Pp. 597, with illustrations. W. B. Saunders Company, 218 W. Washington Sq., Philadelphia 5; 7 Grape St., Shaftesbury Ave., London, W.C.2, England, 1956.

Twenty-six persons have contributed to this book. They have attempted to discuss in great detail the postoperative management of patients in their institutions who have undergone various procedures. The most extensive chapter deals with the management of circulation, shock, respiration, and nutrition. This book should be of value to an institution that desires to set up a recovery room, and it should be useful as a means of evaluating a recovery room already in existence. Moreover, the book should be instructive to surgeons who do not have the facilities described but who might wish to use some of the measures advocated in the postoperative care of patients. The book is well indexed, is printed on excellent paper, and is illustrated extensively. The sources of some of the illustrations are not adequately indicated by the authors.

QUERIES AND MINOR NOTES

SIDE-EFFECTS OF STEROID THERAPY IN CHILDREN

To the Editor:—*What undesirable side-effects have been reported from the use of steroid therapy (corticotropin, cortisone, prednisone) in the treatment of children over a short period of time and in long-range therapy? There appears to be considerable apprehension in the use of the steroids in growing children.* *George L. Popkin, M.D., Rockville Centre, N.Y.*

Answer.—The undesirable side-effects of pharmacological courses of steroid therapy in children over a short period of time are largely those concerned with potassium deficiency and salt retention, with resulting edema. When administered over long periods of time, steroids may reduce the individual's resistance to infection by inhibiting antibody formation and by increasing the dissemination of bacteria or viruses through the tissues to such an extent that he is made more vulnerable and fails to show any clinical evidence of response. For these reasons it is thought fatal cases of chickenpox (varicella) occur in children who are receiving this form of therapy. Again, steroid therapy may change the clinical picture of chickenpox to such an extent that diagnosis is difficult, i. e., by altering the appearance of the dermatological manifestations, or it may permit the rash to continue to occur in characteristic "crops" over a period of four to five weeks.

Untoward effects have also been reported among children with pulmonary tuberculosis, and there is a steadily increasing feeling that herpes zoster and ophthalmia are aggravated by either oral or local use of steroids. The administration of cortisone to hamsters and monkeys prior to infection with the virus of poliomyelitis changes nonparalytic to paralytic poliomyelitis. Prolonged steroid therapy may so usurp the function of the adrenal glands that they may not resume their normal activity when the agent is withdrawn for an indefinite period. Thus, corticotropin may logically be used at the end of prolonged steroid therapy, with gradually decreasing doses. To these effects must be added the "moon face," obesity, and pigmentation of adrenal cortical hyperfunction (Cushing syndrome).

SUDDEN DEATH

To the Editor:—*I was consulted by the coroner concerning the death of a woman who allegedly had been hit in the abdomen by the blunt side of an ax. Death was almost instantaneous. Autopsy revealed no marks on the body, and the findings were negative except for those of acute alcoholism. Is it possible that cardiac arrest could have been instituted by a severe blow over the solar plexus without leaving any telltale marks on the body?* *M.D., North Carolina.*

Answer.—Many cases are on record of acute fatal circulatory failure after injuries that would not ordinarily be regarded as dangerous. Thus, a blunt impact over the solar plexus, precordium, or a testis, pressure on the carotid sinus, or sudden dilatation of the rectum may be immediately fatal. Postmortem examination in such circumstances may disclose no gross or microscopic evidence of trauma. The mechanism responsible for such a death may be vagocardiac inhibition or reflex systemic vasodilatation.

In evaluating such a situation, it should be borne in mind that a person may die unexpectedly and suddenly from natural causes without any postmortem evidence as to the nature of the fatal disease. Thus, a sudden death should not be attributed to cardiac arrest or to reflex vasodilatation due to a blunt impact unless (1) the occurrence of the impact was well documented and (2) a complete postmortem pathological and toxicologic examination failed to disclose the cause of death.

HYPOCALCEMIA IN INFANTS

To the Editor:—*I would appreciate information regarding hypocalcemia with laryngospasm in newborn infants, with particular reference to the incidence between breast-fed and formula-fed babies. Is a commercially prepared formula more prone to giving rise to this condition?*

Boyd C. Hindall, M.D., Lake Geneva, Wis.

Answer.—Laryngospasm is one symptom of hypocalcemia. It is usually accompanied by other signs of tetany, such as carpopedal spasm. It must be differentiated from laryngeal stridor and trauma due to too energetic aspiration of the pharynx in newborn infants. Tetany usually occurs in formula-fed babies and rarely in breast-fed infants. Breast milk has a calcium phosphorus ratio of about 2:1, while cows milk has about a 1:1 ratio. This high phosphorus ratio, combined with hypofunction or immaturity of the parathyroids, seems to be the cause of tetany of newborn infants. There is usually a low serum calcium level, below 6.5 to 7 mg. per 100 cc., and a high phosphorus level of over 6 mg. per 100 cc. Some commercial formulas are usually made from cows' milk, with a calcium-phosphorus ratio of about 1:1. It is recommended, when cows' milk is used as a prophylaxis against hypocalcemia or tetany in infants, that it be diluted 1:2 or 1:3 with water.

MENSTRUAL HEADACHES

To the Editor:—*A 32-year-old woman has had occasional mild to moderate headaches associated with her menses for several years. For the past couple of years these headaches have been occurring with increased frequency and increased intensity just prior to and/or during the menses. Powerful analgesics have given but slight relief. Are any other measures of value to help relieve this incapacitating symptom?*

M.D., Georgia.

Answer.—Some women with a similar complaint have been greatly helped by the administration of ammonium chloride. The patient should be asked to refrain from adding table salt to her food during the two weeks before the onset of the menstrual bleeding. During this time she should take 0.6 gm. of ammonium chloride three times a day. Another simple and effective agent is testosterone propionate. The patient may be given 25 mg. hypodermically on the 10th and the 3rd day before the expected menstruation, or, better still, she can take a 10-mg. tablet of methyltestosterone, or a 5-mg. tablet, sublingually or buccally, daily for 10 days before the expected onset of menstrual flow.

RIDGE OVER FOREHEAD OF YOUNG BOY

To the Editor:—*A boy, now 2 years old, has a disfiguring ridge over the frontal or metopic suture. This is associated and continuous, with a vertical white line over the middle of his nose. Several local pediatricians say it will disappear. However, this deformity, far from disappearing, has, I believe, become more prominent. His head appears to be abnormally long and narrow. This boy is a premature child. Is there anything that can be done to remove this deformity?* *M.D., Canada.*

Answer.—In the absence of further history and physical findings, especially developmental data, neurological findings, and the skull measurements, it is assumed for the purpose of this reply that such findings are normal. The long and narrow shape of the head is not unusual for a child of premature birth. Indeed, some clinicians feel they can frequently detect such children even in the school-age group. This head shape may persist or may eventually become less conspicuous, actually or relatively, as further head and body growth takes place. An osseous ridge palpable or visible over the metopic suture is also not uncommon in premature or full-term infants. When it occurs, it is more apparent in children with narrow heads. The ridge usually be-

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

comes less conspicuous in later years, since it is uncommon among older children and adults. A palpable ridge over the metopic and sagittal sutures in the presence of a long and narrow head might make one suspicious of craniostenosis of these sutures. An x-ray of the skull will rule out this possibility. Neurological findings may not be present until the child is 2 years of age or older. The vertical white line over the midline of the nose has been seen in some children. Its cause and significance are obscure. In the absence of pathological findings, therapy is not warranted for the bony ridge or the white line in the early years of the child's life. The proportionate differences in growth in the early years makes the head deformity more conspicuous, and in most instances it can be expected to become less apparent.

IDENTIFICATION OF THE BLIND

To the Editor:—*Please discuss conditions under which a blind person is identified in the United States. In Germany, a special band is worn on the left arm. In France and Belgium, a blind person is identified by a white cane. In Europe, conditions under which these marks of identification are distributed are the same everywhere: a person must have less than 10% of normal vision to be identified as blind. What are the conditions in the United States under which canes are distributed?*

Daniel M. Rolett, M.D., New York.

Answer.—There is no distinguishing mark by which blind persons are identified in the United States. In fact, there is a definite wish on the part of many blind persons to avoid being conspicuous, quite contrary to the desire of blind beggars who wear dark glasses in order to attract attention and obtain pity for their handicap. All states do have laws restricting the use of white canes to blind persons and, in general, giving blind persons certain rights of way in crossing streets and roads. These laws differ somewhat, and it is recommended that details be obtained by physicians from their own state or local agency for the blind.

DATING OF SEMINAL STAINS

To the Editor:—*Can the stains produced by dried semen be dated?*

M.D., Alabama.

Answer.—Dried stains produced by semen cannot be dated with any degree of accuracy. If seminal ejaculate is dried rapidly on a reasonably clean surface, the spermatozoa may remain intact, the antigenic properties of the fluid may persist, and its acid phosphatase may resist deterioration for many months. Thus, excellent preservation of cellular, immunologic, and chemical characteristics of the fluid does not necessarily indicate that the stain is recent, nor does their deterioration necessarily indicate that the stain is old.

HOSPITALIZATION FOR OVERWEIGHT

To the Editor:—*A recent article in the* New Jersey Medical Journal *states that patients more than 50 lb. (22.7 kg.) over their recommended weight who have failed to reduce on ambulatory treatment should be hospitalized for one to two weeks for good preventive medicine. Despite much additional authoritative evidence in the literature that confirms the value of this, some members of our hospital staff feel that a busy hospital should not waste bed space for such a condition; other members feel that encouraging hospitalization for such obese patients will actually save bed space by lessening the frequency of heart disease and other complications of obesity. We would appreciate an opinion.*

Leonard Casser, M.D., Cresskill, N. J.

Answer.—It is not possible to offer a categorical answer to this question, because of the variables involved in the persistence of overweight. The question as to whether a patient who remains overweight on ambulatory treatment should or should not be hospitalized can only be determined on the basis of the patient and not on the basis of a given amount of overweight per se. Overweight individuals adhering meticulously to a carefully planned and fully observed dietary regimen will lose weight unless there is an underlying metabolic or endocrine abnormality, emotional disorder, cardiovascular or renal problem, or deficiency disease. The persistence of overweight where an adequate reducing regimen has been outlined and strictly adhered to always merits further study to rule out functional or organic factors that may have been overlooked. Whether this should be through further study in the physician's office or through the medium of a period of hospitalization for additional diagnostic study and therapeutic supervision is a matter that can be determined solely on what seem to be the inherent needs in any given situation.

COIN LESIONS SHOWN IN CHEST FILMS

To the Editor:—*A routine chest film of a 60-year-old patient showed a coin lesion in the middle lobe of the right lung. There was no history of illness or undue exposure to tuberculosis. The Mantoux test was positive. All other laboratory work, including Papanicolaou's stain of sputum, was negative. All cultures and guinea pig tests were negative. Resection was done. The pathologist reported a "well encapsulated, calcerous mass measuring 1 cm. in diameter. The lining of cavity is granular. Section shows well demarcated tubercle surrounded by epitheloid lymphocytes and Langerhans' cells." The diagnosis was pulmonary tuberculosis. Cultures from the resected specimen were negative for acid-fast bacilli. No organisms were demonstrated. Is a diagnosis of tuberculosis justified in this patient? If not, what etiological agents could produce such a lesion?*

M.D., Louisiana.

Answer.—In this case the finding of "a well demarcated tubercle surrounded by epitheloid lymphocytes and Langerhans' cells" seems to justify a diagnosis of tuberculosis. On the other hand, that the tuberculosis is open and clinical seems problematical. This probably should be classified as closed, healed tuberculosis, and the patient should be considered well after removal of the lesion. It might be well to keep him on therapy with antituberculosis drugs for a number of months, as a precautionary measure. A good many of the coin lesions with calcification in them have been found to be caused by histoplasmosis, and differentiation between a nodule of this kind caused by tuberculosis and one caused by histoplasmosis is difficult. In the pathology department with which this consultant is familiar, these nodules are all called "granulomas" and are not said to be caused by either tuberculosis or histoplasmosis unless the sections show tubercle bacilli or the histoplasmosis organism.

VITAMIN A AND LOSS OF HAIR

To the Editor:—*Is there any evidence that taking large doses of vitamin A makes the hair fall out from the scalp, as stated in a syndicated newspaper article? If so, what is the dose of vitamin A that can be prescribed safely when such therapy is indicated?*

M.D., Connecticut.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—Diffuse alopecia is sometimes associated with other frank signs of chronic or subacute hypervitaminosis A, such as hepatomegaly, fissuring of the corners of the mouth, and thickening and tenderness of the bone cortex in certain areas. Large doses of vitamin A (e. g., 5,000 to 50,000 I. U. daily) can be administered with safety for a week or 10 days in patients with signs of frank or latent deficiency. For ordinary prophylaxis, daily dosages should be limited to 3,000 I. U.

Answer.—The question regarding hypervitaminosis A and hair loss has a timely answer in a report by Elliott and Dryer in The Journal (161:1157 [July 21] 1956), where a case of hypervitaminosis A in an adult is reported. No hair loss was noted in this patient who received vitamin A in a dosage of 50,000 units three times a day for over seven months. This report also refers to other cases of hypervitaminosis A described in the literature where hair loss was noted along with symptoms referable to the bones and joints, notably bone tenderness, and skin changes. The dosage level of vitamin A that produces symptoms of hypervitaminosis A undoubtedly remains quite variable because of numerous factors subject to considerable biological variability.

MAINTAINING TISSUE TONE WHILE REDUCING

To the Editor:—*Would general body massage, done by a trained physiotherapist, be useful to maintain good tissue tonus in a patient who has been hospitalized to reduce his overweight of 50 lb. (22.7 kg.)? He has not yet developed signs or symptoms of additional disease. Are there any other benefits to "general body massage?" How often would it be recommended?* *Leonard Casser, M.D., Cresskill, N. J.*

Answer.—Opinion varies as to the extent of usefulness of massage in maintaining "tissue tonus" in a patient who has lost weight. Depending on the method of application and type of massage used, the psychic effect can be either a stimulative one or a sedative one. Blood flow to and from and lymph return from an area may be increased by the use of massage, and, secondary to this, a mild increase in metabolic activity may result. It is doubtful that massage alone can be expected to produce the desired effect in the patient who has lost weight. Probably more effective in bringing about this desired result would be the use of such active exercise as the patient's physical limitations permit. The benefits derived from carefully prescribed and graduated activity will undoubtedly exceed any of those derived from general body massage given every other day.

REMOVAL OF FLUORIDES FROM WATER

To the Editor:—*Will a water softener remove the fluoride compound such as is being used by the city of Chicago in their fluoridation program?* *John B. Jacobs, M.D., Chicago.*

Answer.—The ordinary household type of water softeners will not remove fluoride compounds from water. The commercial type of water softener known as a demineralizer will remove a major portion of the fluoride compounds added to water in fluoridation programs. These demineralizers will remove fluoride compounds so long as they are ionizable. Should a small amount of fluoride combine with organic (unionizable) compounds, these will not be removed.

ARTERIOSCLEROSIS AND DIET

To the Editor:—*A patient who eats cottage cheese twice daily rarely eats meat or fish. Would this be a good diet for one who has angina pectoris or arteriosclerotic heart disease? In other words does this kind of cheese produce too much cholesterol for such a patient? He adds moderate amounts of cream to the cheese.* *M.D., Indiana.*

Answer.—The diet outlined above is certainly not a desirable diet for a patient with atherosclerotic heart disease for several reasons. 1. It is necessarily too high in fats (including cholesterol and saturated fats). 2. Cottage cheese being the main source of protein, it is probably lacking some of the essential amino acids, vitamins, and minerals. This constitutes a dietary imbalance that, according to modern concepts regarding the pathogenesis of atherosclerosis, probably has deleterious effect on the vascular tree, particularly the coronary arteries. The patient should be advised to modify his dietary habits by substituting lean meats for at least part of his cottage cheese–cream intake. In general, a well-balanced diet deriving not more than 25 to 30% of the daily calories from fats and containing liberal amounts of fresh and cooked vegetables and whole grain products, is considered as optimal at present.

LACTATION IN INFANCY

To the Editor:—*A 10-month-old girl has milk in one breast. A small amount can be expressed on pressure. What, if anything, should be done? Is it likely to go away of itself?* *M.D., Virginia.*

Answer.—The presence of a small amount of thin milky secretion in the breast of an otherwise normal 10-month-old female infant has no significance. Spurious lactation in infancy is considered to result from stimulation of the breasts by maternal hormones that pass through the placenta to the infant during fetal life. The condition requires no treatment and can be expected to clear spontaneously if the breast is not irritated by tight clothing or manipulation.

BATHING NEWBORN INFANTS

To the Editor:—*Please review the current trend of thinking concerning the bathing of newborn infants with a mild soap and water as opposed to a method of oiling them with one of the acceptable baby oils. Various sources indicate that most of the larger obstetric hospitals have completely abandoned the use of oils.*

James M. Covington Jr., M.D., Wadesboro, N. C.

Answer.—Neither method is satisfactory. The current thought is best expressed by the Standards and Recommendations for Hospital Care of Newborn Infants (American Academy of Pediatrics, 610 Church St., Evanston, Ill., 1954), section 7, page 34: "No water or oil bath should be given during the hospital stay"; page 81: "Blood should be removed with cotton and water. Only unsightly amounts of vernix caseosa are to be removed. This should be done with sterile cotton. The skin thereafter should be left alone. Buttocks are to be cleaned with warm tap water with as little rubbing as possible. If needed, oil may be used over the diaper area."

RECURRENT BILIARY COLIC

To the Editor:—*A 50-year-old woman with a typical clinica history of recurrent biliary colic showed on three differen occasions a nonfilling gallbladder on Graham-Cole serie: There is no history of jaundice. At operation the gallbladd and biliary tree appear normal to visualization and palpatio The pancreas is apparently normal to palpation. What, if an procedures should be performed at the operating table?* *M.D., New York.*

Answer.—In the absence of objective evidence of disease the gallbladder at operation, cholecystectomy or cholecystostor should not be done. Careful exploration of the abdomen shou be made to exclude the possibility of chronic disease elsewhe The results after removal of a gallbladder that appears norn have not been good in a large proportion of patients. A hi incidence of biliary dyskinesia has been encountered. If syr toms persist after recovery from the operation, it might be w to place the patient on a low-residue, nonlaxative diet and administer belladonna and phenobarbital. In many patie hypermotility of the colon rather than disease of the gallblad is responsible for these symptoms.

PULLING TEETH DURING POLIOMYELITIS SEASON

To the Editor:—*The following quotation from the* Newsletter of the Medical Society of the State of New York *may be of interest in connection with the Query and Minor Note on "Pulling Teeth During Poliomyelitis Season" in* The Journal, *Sept. 29, 1956, page 527. "The State Health Department's recommendation that poliomyelitis vaccination continue during the summer does not apply to elective injections of other than polio vaccine. Probably a person who has received two or three injections of poliomyelitis vaccine faces little risk of getting paralytic polio even if the elective procedures are carried out in an area where the disease is prevalent. However, since the number of persons who have completed the course of three injections is still relatively small, the Department feels that the wisest course for this summer is to recommend postponement both of such elective injections and of elective nose, throat and mouth operations, especially in areas where polio is prevalent. Drs. Jonas Salk and David Bodian, with whom we have discussed the question, are in accord with this policy. As in the past, the avoidance of immunizations in infants under six months of age is not recommended since the hazard of polio is far less in this age group than the hazard of the other diseases against which infants are routinely immunized."*

State Officials Favor Vaccine Grants Extension • •
Democrats Set to Organize Committees Again • •
Casualty Care Program Undergoing Reevaluation • •
Cerebral Palsy Collaborative Study Launched • •
Military Surgeons Hear VA Research Potential • •

ENDORSEMENT OF HEALTH PROGRAMS BY STATE HEALTH OFFICIALS

Salk Vaccine.—The first public endorsement of extension of the Salk vaccine grants program for another year has been made by state and territorial health officers. This was one of the recommendations during their annual conference in Washington, D. C., with the surgeon general of the Public Health Service and the chief of the U. S. Children's Bureau. Without elaboration, the group voted that "the federal government should continue its financial participation in the poliomyelitis vaccine program for the next fiscal year."

Dr. Leroy Burney, PHS surgeon general, earlier in the session spoke at length on the poliomyelitis program, but he took no stand on whether it should be extended beyond next June 30. He noted that for the first time since the vaccine was introduced manufacturers report they have on hand more than 17,000,000 cc. cleared and undistributed. He estimated total cases of the disease by the end of this year will amount around 16,000, the lowest since 1947.

He said it would seem reasonable to assume that vaccination has played an important part in holding down incidence of paralytic poliomyelitis this year. With a good supply on hand he said that now is the time to protect the unprotected—infants and preschool children, elementary and high school children, college students and expectant mothers—and to complete the three-injection schedule.

Funds for Health.—State health officials also made the following recommendations: (1) extension of the Hill-Burton hospital construction program for another five years beyond June 30, 1958, with the full authorization of 210 million dollars for funds for both the basic and the clinic-nursing home programs; (2) an increase in funds for water pollution control construction grants, from the present 50 million dollars a year to 100 million dollars, and a total authorization of at least 1 billion dollars; similarly an increase in funds for air pollution control; (3) development by the PHS of legislation dealing specifically with the prevention and control of chronic disease and the promotion of the health of the aged, including a state grant-in-aid program; and (4) promotion by the PHS of a bill that would permit the PHS to cooperate with communities in construction of hospitals jointly serving Indians and non-Indians and that would make available to non-Indians space in existing Indian hospitals as well as medical services, subject to proper safeguards for rights of the Indians.

The Association of State and Territorial Health Officers meeting at the same time recommended that its president name a committee for long-range planning in public health, including promotion of legislation. The association elected these officers: Drs. Franklin D. Yoder, Wyoming state health officer, president; Herman Hilliboe, New York, vice-president; and Mack L. L. Shanholtz, Virginia, secretary-treasurer.

ELECTIONS AND HEALTH PROGRAMS

With at least another two years of coalition government ahead, the Democrats are set to organize the House and Senate again starting Jan. 3. Excepting the House Interstate and Foreign Commerce Committee, all committees concerned in varying degree with health matters will be headed by the same chairmen as in the 84th Congress. Rep. Oren Harris (D., Ark.) will assume the full chairmanship of the Interstate Committee in January, to replace Rep. Percy Priest (D., Tenn.) who died after the adjournment of the 84th Congress.

The elections brought the defeat of a veteran member of the House Armed Services Committee, Rep. Dewey Short (R., Mo.). He played a part in the last Congress in the bill commissioning osteopaths in the armed services. Returned to the Congress after a lapse of two years is Dr. Will Neal (R., W. Va.). This brings the total of physicians in the 85th Congress to five. The others are Drs. Ivor Fenton (R., Pa.), Antonio Fernos-Isern of Puerto Rico, Walter Judd (R., Minn.), Arthur Miller (R., Neb.), and Thomas Morgan (D., Pa.).

Chairmen of the committees important to the medical profession for the upcoming session include Senators Lister Hill of Alabama, Labor and Public Welfare; Richard Russell of Georgia, Armed Services; Harry Byrd of Virginia, Finance; Olin Johnston of South Carolina, Post Office and Civil Service; and John McClellan of Arkansas, Government Operations. Those in the House include Representatives Jere Cooper of Tennessee, Ways and Means; Carl Vinson of Georgia, Armed Services; Olin Teague of Texas, Veterans Affairs; Tom Murray of Tennessee, Post Office and Civil Service; and William Dawson of Illinois, Government Operations.

There is every reason to believe that with the President barred by constitutional amendment from a third term, Democrats in Congress will look carefully into any medical or other domestic bills proposed by the administration. At the same time Democrats may be expected to press for their own program with an eye on retaining control of Congress in 1958 and recapturing the presidency in 1960.

OSTEOPATHS IN THE ARMED FORCES

The Department of Defense has laid down the rules it will apply to commissioning of osteopaths as military medical officers, an authorization voted by the last Congress. To be eligible for a commission, an osteopath must meet the following requirements, among others: 1. He must be a graduate of a college of osteopathy "whose graduates are eligible for licensure to practice medicine or surgery in a majority of the states, and be licensed to practice medicine, surgery, or osteopathy in one of the states or territories of the United States." 2. He must be recommended by one of the three military surgeons general and "possess such qualifications as the secretary concerned may prescribe." 3. He must have completed (*a*) a minimum of three years of college work prior to entering college of osteopathy, (*b*) a four-year course with a degree of doctor of osteopathy from a school approved by the American Osteopathic Association, and (*c*) 12 months or more of internship or residency training approved by

---

From the Washington Office of the American Medical Association.

the American Osteopathic Association. The regulations were signed by Dr. E. H. Cushing, deputy Assistant Secretary of Defense for health and medical matters.

CIVIL DEFENSE

The country's civil defense casualty care program is undergoing a reevaluation by a 10-man medical task force. The group will make recommendations for defining the broad scope of medical care in the event of enemy attack on the nation and also will review lists of civil defense medical supplies and equipment and their functional packaging. The Federal Civil Defense Administration explained that the reevaluation stems from two logistical field tests of the casualty care program that centered around the agency's 200-bed emergency hospital. The first test was staged by the 68th Medical Group at Fort George G. Meade, Md., last April, when over 400 simulated casualties were processed through the hospital. A second test was held in June at Fort Sam Houston, Texas, with the Brooke Army Medical Center and the Army Medical Service School staffs. A simulated bomb drop produced 823 casualties, who were processed through collection points, treatment centers, and an emergency hospital.

The agency found it would have to plan for a larger number of immediate casualties and provide care for a longer period after an attack than previously planned. Earlier assumptions of the FCDA were based on caring for casualties for a three-week period after an attack. The 10-man committee includes Col. Joseph R. Schaeffer, Walter Reed Army Research Institute; Dr. James B. Mason, American College of Surgeons; Dr. Harold C. Lueth, Chairman, American Medical Association Committee on Civil Defense; Dr. Max E. Lichter, member of the A. M. A. Committee; Dr. Max M. Van Sandt, director of the FCDA medical care division; Milton C. Skolaut, U. S. Clinical Center; Major Harriet C. Werley and Capt. Eveline C. Hughes, Walter Reed Research Institute staff; Ruth C. Smith, director of Nurses, Delaware County Hospital; and Margaret K. Schaefer, chief nurse, FCDA health office.

LONG-TERM RESEARCH

The Public Health Service has announced the start of a broad coordinated research program that will seek to identify factors responsible for cerebral palsy, mental retardation, blindness, and deafness. The collaborative study is expected to take 10 to 20 years to complete, and at its peak more than 6,000 persons will be studied annually. Data to be collected by some 10 participating medical institutions will include complete family history, pregnancy and prenatal histories, a detailed account of events at birth, and a complete physical and psychological history of each child during his initial stay at the hospital.

Infants who show signs of stress, defects in development, or neurological problems will be selected for follow-up and will receive periodic psychological and neurological examinations. The PHS expects that the studies will clarify the role of heredity, brain injury and brain hemorrhage, lack of oxygen, difficulty in breathing, prenatal and postnatal infections, and anemia of the newborn infant in the development of neurological disorders.

Awards of more than $700,000 for a four-year study in this field have been announced for Yale University School of Medicine and Brown University. Yale's grant for the first year is $107,799 and Brown's, $97,633. More than a million dollars a year will be awarded under the collaborative program that is being coordinated by the National Institute of Neurological Diseases and Blindness. The institute will analyze all data obtained from the participating medical centers.

The study at Yale will be under the general direction of Dr. Gilbert H. Glaser, associate professor of neurology, and the study at Brown, under Dr. Eric Denhoff, medical director of the Meeting Street School, institution for the crippled. Studies at Brown will be made through the Cerebral Palsy Clinic at Rhode Island Hospital and the Providence Lying-In Hospital.

RESEARCH BY THE VA

The Veterans Administration has a serious responsibility to carry out medical research in the disabilities and diseases of the aging veteran population, according to the deputy chief medical director of the VA. Dr. Roy A. Wolford, addressing the 63rd annual meeting of the Association of Military Surgeons of the United States, noted that diseases of older veterans are primarily of a chronic nature and usually require long-term hospitalization.

He stated: "There has been a significant increase in the number of veterans hospitalized with heart disease, respiratory difficulties and diseases of the blood vessels, cancer, diseases of the digestive and genito-urinary system, arthritis and other bone and joint disorders. Their great number provides the Veterans Administration an opportunity to investigate these diseases in order to be able to offer more effective methods of diagnosis, treatment and rehabilitation. Nowhere else in the world are found patients in all stages of these diseases in such large number or under conditions so suitable for clinical investigation as in Veterans Administration hospitals."

Col. Sheldon S. Brownton of the office of the Assistant Secretary of Defense for health and medical affairs outlined the Defense Department program for encouraging medical schools to include in their curriculums those phases of medicine encountered in disaster situations, both military and civilian. He said that the Public Health Service and the Federal Civil Defense Administration are now providing funds for this program along with the Defense Department.

The delegates to the meeting elected Col. Amos R. Koontz as president, and these vice-presidents: Col. Charles R. Mueller, Brig. Gen. H. H. Twitchell, Major Gen. Wallace H. Graham, Dr. John W. Cronin, and Major Gen. James P. Cooney.

PERSONNEL

Dr. Martha May Eliot is retiring at the end of this year as chief of the United States Children's Bureau, Department of Health, Education, and Welfare. Dr. Eliot, who has been chief of the bureau since 1951, will become professor of maternal and child health at Harvard University. . . . Forrest E. Linder, Ph.D., formerly with the United Nations Statistical Office, has been appointed director of the government's new program for annual surveys of illness and disability in the U. S. The program was authorized by the last Congress, and $700,000 is available this fiscal year. Dr. Linder, who received a doctor of philosophy degree from Iowa State University, was one-time deputy chief of the U. S. Office of Vital Statistics.

IMMEDIATE MANAGEMENT OF THE INJURED URETER

Vincent J. O'Conor, M.D., Chicago

• *Serious injuries to the ureter have often resulted during trauma, such as stab and gunshot wounds, to the abdominal or pelvic organs, but they also occur occasionally during surgical procedures on neighboring structures, diagnostic procedures such as cystoscopy, and therapeutic procedures such as irradiation. Preoperative urographic study is important in planning the operative attack on certain abdominal, pelvic, and retroperitoneal spaces. Preoperative introduction of ureteral catheters should be utilized more frequently to facilitate identification of the ureters during difficult dissections. The unintended inclusion of a ureter in a ligature must be corrected promptly; the release of such a ligature is more readily accomplished by teamwork between the surgeon and the urologist. The possibility that a ureter has been injured should always be considered whenever oliguria or anuria is observed during the first eight hours after any surgical operation in the vicinity of the ureters. If evidence of injury or ligation is found, prompt repair, with provision for tissue drainage, is imperative.*

The ureter is frequently injured during surgical or urologic manipulative procedures. Gynecologic operations, such as hysterectomy, either vaginal or abdominal; the removal of the ovaries or fallopian tubes; excision of intraligamentous cysts or tumors; and vaginal repair for prolapse of the uterus, may be accompanied by ureteral injury. Operations on or within the abdomen, especially resections of the sigmoid and rectum; unusual conditions of the appendix, especially when retroperitoneal; the removal of atypical pancreatic and mesenteric cysts; and other less common procedures, are sometimes complicated by ureteral injury. Occasionally, a portion of the ureter, along with a segment of the bladder, is present in an inguinal hernial sac. In such a case, injury of the ureter may occur during surgical repair. In cystoscopic procedures, especially during ureteral manipulation of calculi, the ureter may be torn or perforated. Strictures of or kinks in the ureter, especially when long-standing ureteritis has been present, will present anatomic changes that predispose the ureter to injury by even the slightest trauma.

The most common ureteral injury brought about by the urologist is that due to perforation from the various instruments designed to facilitate the passage of ureteral calculi. Perforation of the ureter secondary to general body trauma is unusual. Injury due to external stab and gunshot wounds is seen in wartime but is uncommon in time of peace. After irradiation, the ureter may become necrotic and perforate into the surrounding tissues or into an adjacent viscus; but, more commonly, the wall becomes thickened and stenotic, and ureteral obstruction and hydronephrosis result. Ureteral injuries have become somewhat more frequent in recent years due to the increasing number of radical surgical procedures in the treatment of carcinoma of the lower part of the intestine, uterus, and pelvic adnexa. A marked increase in the number of injuries associated with cystoscopic procedures has been noted in the past 10 or 15 years.

The problems surrounding possible injury of the ureter are much more difficult and obviously more complicated for the abdominal surgeon and gynecologist than are those for the urologist. The latter is dealing directly with this structure and will be aware of the possibility of injury at all times. Failure to recognize the accident at the time of operation rules out the opportunity for immediate repair, and the most favorable time for repair of such ureteral damage is at the time of the mishap or as soon afterward as possible. The longer the situation exists unrecognized, the more difficult the anatomic correction and the more serious the complications.

Prevention of Ureteral Injury

Teamwork between the urologist and the gynecologist or abdominal surgeon will greatly lessen the number of surgical accidents to the ureter and bladder. While there is no single method that will insure prevention of these injuries—and it is obvious that they may be expected to occur even in the hands of the most experienced and capable physician—a preoperative knowledge of the anatomy and function of both kidneys and ureters is of great value to the surgeon.

From the Urologic Department of Chicago Wesley Memorial Hospital and Northwestern University Medical School.

Read before the Section on Surgery, General and Abdominal, at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

These can usually be demonstrated by a satisfactory excretion urographic study. If the information is incomplete, a retrograde study should be done. The careful surgeon will insist upon having these data before performing operative procedures that might be complicated by ureteral injuries.

Anomalies of the ureters and kidneys and possible distortions and deviations from their normal courses will be demonstrated by excretion or retrograde pyelograms. Renal fusion, renal ectopia, changes due to previous urinary infections, and the presence of cysts or tumors should be apparent before the surgical procedure. It is surely not too much to ask that an excretion urographic study be done prior to elective operative interventions of such magnitude that ureteral ligation or injury might result during a difficult dissection. So many lesions of the upper urinary tract are symptomless, or silent, that preoperative urograms should seem as important to the surgeon as do blood chemistry studies and other commonly applied laboratory procedures. Intestinal tumors occasionally involve the ureter by encirclement without localizing symptoms.

The urologist has, to a considerable degree, convinced the gynecologist and the abdominal surgeon of the value of use of the indwelling urethral catheter prior to and immediately after extensive operative procedures on the structures adjacent to the ureters and bladder. I urge the placing of indwelling ureteral catheters before the operation as well. Prior to the discovery of modern urinary antiseptics, there was some justification for feeling that the risk of setting up infection in the upper urinary tract might outweigh the help that the presence of these catheters might give in identifying the ureters more readily; however, this objection lacks validity today. It is true that the placing of catheters entails a cystoscopic procedure carried out by a well-trained person, who must see that the catheters are properly inserted and that they do not slip down during the operation. The latter can readily be effected by temporarily suturing the ureteral catheters to adhesive tape attached to the indwelling urethral catheter. It is true that occasions will occur where the ureters cannot be easily identified even with the catheters in place. However, in most of these instances the ureteral injury will become rapidly apparent by the appearance of the catheter during the course of the dissection. The objection that, by having catheters in place, the surgeon will be given a false sense of security against ureteral injury does not warrant serious consideration. I favor preoperative ureteral catheterization, and at Chicago Wesley Memorial Hospital there is an understanding that some member of the urologic service will be available for this purpose at all times.

Therefore, prevention of ureteral injury requires (1) recognition of the fact that such injuries can and will occur in the most experienced hands; (2) recognition that a knowledge of the relationship of the ureters to the abnormal structures that one is planning to remove should be obtained preoperatively by urography; and (3) recognition that the preoperative placing of ureteral and urethral catheters will assist the surgeon in avoiding a surgical accident to the ureter and bladder. The surgeon should be especially diligent in identifying the ureter (1) where it crosses the bifurcation of the iliac vessels; (2) in the ovarian fossae; and (3) where it passes behind the uterine artery. When the dissection is deep in the pelvis, he should at all times have in mind the location of the bladder wall and the intravesical portion of the ureter.

Most of the avoidable injuries to the ureter result from lack of vigilance in the placing of clamps and ligatures. Curiously enough, it seems that more ureteral and bladder injuries follow procedures where the dissection was reported as easy and satisfactory than where it was reported as difficult. In patients with extensive chronic inflammatory disease, large uterine or ovarian tumors, and infiltrating neoplasms of the colon, the surgeon will more often be accurately aware of the danger of ureteral injury and will go to greater pains in identifying the ureter in an early stage of the surgical dissection.

Treatment of Ureteral Injury

The immediate treatment of injury to the ureter (I am not taking into consideration delayed treatment) may be relatively simple or annoyingly complicated. When accidental ligation is recognized during operation, release of the ligation, with or without the passage of a ureteral catheter, will usually be adequate. If section of the ureter has occurred, one must accurately identify the proximal and distal segments and unite them, preferably over a catheter, by direct end-to-end anastomosis. Chromic absorbable surgical suture (0000) on an atraumatic needle is the suture of choice. Two or three mattress sutures suffice.

Since the immediate management of an injured ureter entails not only anatomic restoration but also insurance against urinary extravasation, the provision for adequate drainage, both intraureteral and alongside the ureter, must be of prime consideration. The introduction of a ureteral catheter by the cystoscopist while the surgeon is searching for or attempting repair of the severed ureter may be most helpful. Likewise, the point of catheter arrest in the case of ureteral ligation may quickly define the area to be examined by the operating surgeon. If the situation does not warrant prolonged search for the area of injury or if repair is too difficult or considered unsatisfactory, nephrostomy should be performed after the abdominal wound has been closed, with provision for adequate drainage. It is well known that complete, sudden, simple ligation of the ureter is usually followed by an asymptomatic renal atrophy preceded by a complete unilateral renal suppression. All too often the surgeon may be tempted to follow this easy path out of the difficulty of unilateral ureteral injury. However, this would be most unwise unless previous renal functional and urographic tests had demonstrated a normal kidney on the unaffected side. Even then one would recommend nephrostomy reluctantly, except in the unusual instance where later surgical procedures or complications might outweigh the loss of function of one kidney.

Releasing of ligation should always be seriously considered when complete anuria has been shown by cystoscopic examination to be due to bilateral ureteral occlusion. In the past, there has been a high mortality from this secondary operative procedure; and the surgeon has, therefore, preferred to perform a bilateral nephrostomy or pyelotomy. The release of a ligation can be greatly simplified if the surgeon and urologist cooperate in its performance. The surgeon reopens the laparotomy wound and, with the aid of the cystoscopist, can readily detect the points of constriction when the ureteral catheters (preferably 7 to 9 F. in size) are used to prod the area of obstruction. After release of a ligation, the catheters should be passed to the renal pelves and left in place for from 5 to 10 days. Without the help of the urologist, the surgeon may conduct a prolonged search for the areas of ligation, remove the wrong sutures, and generally grope in the edematous tissue without finding the offending ligatures.

In my experience, the most satisfactory manner of handling the problem of intraureteral drainage is to have the surgeon insert a 6 to 9 F. ureteral catheter, either woven, latex rubber or polyethylene, so that one end is in the renal pelvis and the other end coils up in the bladder. The latter end is then grasped with a forceps or cystoscopic rongeur and pulled out through the urethra. An indwelling urethral catheter should be placed in the bladder and the ureteral catheter fastened securely to it to prevent its slipping down the ureter into the bladder. If the ureter has been injured low in the pelvic portion, within 3 to 5 cm. of the bladder, reimplantation of the proximal portion to the bladder should be effected, using either the pull-through-and-suture technique or the eliptical anastomosis with mucosa-to-mucosa suture as described by Nesbit. When irreparable injury has occurred in the lower half of the ureter, one can either transplant it to the sigmoid or, if possible, effect a ureteroureterostomy. I have never performed the latter procedure, but it has been carried out successfully by Higgins, Parke Smith, and others.

Prevalence of Ureteral Injuries

Any patient who shows oliguria or complete anuria during the first eight hours after operation should be suspected of having ureteral injury or ligation, if the surgical procedure has involved the region of the ureters. In unilateral occlusion, there may often be no symptom whatever, but partial anuria, pain in the flank or abdomen, and elevated temperature may suggest the condition.

Ureteral injuries from perforation during the cystoscopic extraction of calculi from the lower part of the ureter have increased materially in recent years. Mechanical stone extractors are usually the instrument of injury. At the time of extraction, the ureter may be more vulnerable to puncture because of the inflammatory or necrotizing action of a long-impacted calculus. Ureteral injuries occurring as a result of cystoscopic procedures and those associated with external trauma, such as gunshot and stab wounds, make up a chapter too vast to consider here. Rusche and Hager have completed a comprehensive study of 103 ureteral injuries encountered by them during the years 1930 to 1950. The increase in ureteral injuries after cystoscopic attempts at ureteral stone extraction was emphasized, as were such injuries due to gunshot wounds. They felt that, despite the increase in the number of patients subjected to extensive radical pelvic and abdominal surgery, a comparison of the period 1940-1950 with the preceding decade indicated that the number of surgical injuries remained about the same.

Summary

The gynecologist, general surgeon, and urologist must constantly bear in mind the possibility of ureteral injury during operative procedures in the abdomen, pelvis, and retroperitoneal spaces. Preoperative excretion urographic studies are most important in considering the operative attack. Preoperative introduction of ureteral catheters should be utilized more frequently to assist the surgeon in more readily identifying the ureter. These catheters should be fastened to the indwelling urethral catheter. The release of a ligation is more readily accomplished by teamwork between the surgeon and urologist. Early surgical repair, with adequate provision for tissue drainage, is paramount after injury or ligation has been discovered.

720 N. Michigan Ave. (11).

PRIMARY CARE OF THE URINARY TRACT IN SPINAL CORD INJURY

Herbert S. Talbot, M.D., Boston

• *The structural changes that follow retention of urine in a paralyzed bladder must be prevented by adequate drainage from the beginning. With a catheter in place, the bladder regains its ability to fill and empty by reflex action with a certain regularity. It can be conditioned by the method of tidal drainage within a period of 6 to 12 weeks. Meanwhile a program of high fluid intake, acidulation of the urine, and muscular exercise is carried out to prevent lithiasis. The catheter can then be removed, and the observance of a certain program of fluid intake and other habits enable many patients to maintain an adequate urinary capacity, to empty the bladder completely, and to get along without wearing any apparatus.*

The management of the bladder in patients with spinal injury or disease has two aims: to provide the patient with a micturitional function that will not impede his efforts toward rehabilitation and to preserve the integrity and function of the upper urinary tract. Fortunately, these aims are not incompatible; indeed, the best assurance of a healthy upper urinary tract is a normally functioning bladder. If this can be achieved and if, at the same time, the hazard of formation of renal calculi because of disturbed calcium

---

Chief of Paraplegia and Urology, Veterans Administration Hospital (West Roxbury), Boston.

Read in the Panel Discussion on Rehabilitation of Patients with Paraplegia before the Section on Physical Medicine at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

metabolism can be obviated, the disastrous train of events that has in the past led so many of these patients to invalidism and death may be averted.

There are two principles upon which the course of management that meets these demands is based. First, any functional disturbance, such as that caused by impaired innervation, will eventually result in reciprocal structural alteration; furthermore, if the dysfunction leads to secondary consequences, such as infection, secondary changes will develop and may become so marked that, even if the innervation were to be restored, the end-organ might remain incapable of normal activity. The object, therefore, is to prevent the development of such changes, to recognize them if they have already developed when the patient is first seen, to evaluate their contribution to the dysfunction, and, finally, to treat them if possible. The other basic principle is that the bladder is a spinal reflex organ with an overlay of controls from higher centers. Primary neurogenic dysfunction may result from involvement of the spinal center itself or from interruption of the pathways through which it communicates with the brain.

To guard against structural alteration, one must insure adequate drainage from the beginning. Overdistention leads to changes in the bladder wall; these are hastened by infection, which soon develops. Even when the patient can void, if there is residual urine (which is often the case), infection will follow. Catheterization is not without its risks and inconveniences, but these add up to a good deal less than the danger of infection in an inadequately drained urinary tract. Furthermore, by preserving the structural integrity of the bladder, early drainage hastens the day when, the process of retraining having been completed, artificial drainage may be discontinued and the patient may void naturally through the urethra.

Having secured the advantages of early drainage, one may expect that, as the patient emerges from the period of spinal shock and as the reflex activity below the level of the lesion is resumed, the bladder, although deprived of its controls from higher centers, will fill and empty reflexly with some degree of rhythmical regularity. This is the so-called automatic bladder; but the term is a bad one, and the function represented is not satisfactory. Such a bladder tends to be hypertonic; its emptying contractions are inefficient, and, as a result, it accumulates a considerable amount of residual urine. There is, of course, no control of micturition. In the name of expediency, treatment has often taken the form of permanent suprapubic drainage, permanent urethral catheterization, or the wearing of some cumbersome type of incontinence apparatus. Most of these undesirable eventualities can be avoided.

The Reflex Bladder

Management is based upon the fact that reflex activity of any kind can be conditioned to greater consistency and efficiency. Tidal drainage provides a method of applying this conditioning process and achieving that degree of consistency and efficiency that is the primary requisite of good function. If the patient is seen early, before any complicating factors have developed, this can be accomplished in an amazingly short time, perhaps as little as six weeks. It should seldom require more than three months. The catheter may then be removed and, by combining a controlled fluid intake with careful habit training, the patient may maintain an adequate capacity, empty his bladder completely, and have reasonably good control, so that it is unnecessary for him to wear any apparatus. It should be possible to achieve and maintain such a result in at least two-thirds of all patients. The program for prevention of calculi is simple but effective. It includes a high fluid intake (3,500 to 4,000 cc. daily), acidulation of the urine, muscular activity to avoid the mobilization of calcium from the skeleton, and adequate drainage. On such a regimen, the incidence of primary renal calculus should be less than 2%. The weeks immediately after injury are most critical.

This is not the time to discuss the exact techniques employed in the routine urologic care of these patients, such as the conditioning of the reflex bladder, the details of habit training, the indications for nerve blocks or nerve interruptions in special cases—and I should like to emphasize that these seem to me to be indicated only in special cases—and the indications for and technique of transurethral resection, which, in my experience, has been necessary in perhaps one out of every four patients. It should be remembered that there is no place for mere expediency in the attack on this problem. Nothing but the best will do if the two aims mentioned earlier are to be achieved. If they are not, the patient cannot anticipate a successful rehabilitation and probably will not live very long; he will certainly not enjoy good health.

Comment

It is only fair to point out, however, that this method of treatment is not easy to follow. It requires meticulous daily attention to detail and seemingly endless explanations to patients, nurses, attendants, and, in particular, to other doctors who are concerned in the patient's care. Above all, it demands the understanding and the willing cooperation of the patient, particularly during the difficult weeks of habit training shortly after the removal of the catheter. There is no way of avoiding this if the best results are to be obtained; I am not aware of any short cuts. The various surgical procedures that have at one time or another been suggested (some of which still have a useful place) are not substitutes for the fundamental program of conditioning of the reflex bladder but rather are supplements to it, to be employed when and if they are required, according to the needs of the individual patient. The other expedients to which I have referred briefly are easier for the doctor and make fewer demands upon the patient's understanding and cooperation. The only thing to be said for the more difficult approach recommended here is that it gives the majority of patients a much healthier urinary tract and keeps them alive and well longer.

NEUROSURGICAL ASPECTS OF TREATMENT FOR PATIENTS WITH SPINAL CORD INJURIES

Irving S. Cooper, M.D., New York

• *The first decision for the neurosurgeon after an injury to the spinal cord is whether any immediate neurosurgical maneuver is indicated. Neurological and roentgenographic examination determine whether fracture-dislocations need to be reduced, whether traction or laminectomy are necessary, and whether post-traumatic fragments of bone, intraspinal hematomas, or herniated intervertebral disks require attention. In many cases early laminectomy is actually the conservative course of action. Later problems for the neurosurgeon, from three months to several years after the injury, concern especially the intractable pain and spasticity that generally accompany paraplegia. Various procedures, including chordotomy, offer reasonable hope of relief of pain; alleviation of spasticity may be afforded by peripheral neurectomy, subarachnoid alcohol block, rhizotomy, or subtotal spinal chordectomy.*

Since I shall discuss only the aspects of the care of patients with spinal cord injuries that are directly related to neurosurgical management, it will be necessary to integrate these remarks with those of the other speakers on the panel (this issue, pages 1203-1204 and 1208-1209) in order to arrive at an over-all picture of management for patients with spinal cord injuries. As Dr. Covalt has stressed, the patient with spinal cord injuries should be taken directly to the x-ray department so that roentgenograms might be obtained without any additional moving of the patient. It is at this point, while the patient is still in the x-ray department, that a decision should be made as to whether neurosurgical care is immediately indicated, assuming that the neurosurgical consultant has been called to see the patient. After a detailed neurological examination and appraisal of the roentgenograms, the first decision that the neurosurgeon is called upon to make is whether any immediate neurosurgical maneuver is indicated.

Early Neurosurgical Treatment

In cases of fracture-dislocation of the cervical spine in which reduction must be carried out, this is usually performed properly by skeletal traction applied to the skull. The method that is commonly used is the application of Crutchfield tongs to the crown of the skull or wires passed through trephine openings in the skull. Thus, in a great majority of cases of fracture-dislocation of the cervical spine, proper reduction with decompression of the spinal cord, which is the initial treatment of choice, can be accomplished by skull traction. In cases in which skeletal traction properly applied has not been able to reduce the dislocation or in which a subarachnoid block persists despite adequate use of traction, cervical laminectomy with decompression is indicated. Another indication for open operation is progressive increase in neurological deficit despite satisfactory skeletal traction. In some instances of violent injury to the cervical portion of the spinal cord, acute herniation of the intervertebral disk also occurs. Usually, clinical and roentgenographic studies will aid in the diagnosis of this lesion, although occasionally myelography is necessary. In such instances, laminectomy with decompression of the spinal cord should be performed.

In cases of thoracic and lumbar fracture-dislocation, the subject of laminectomy versus more conservative management continues to be controversial, although an increasing number of neurosurgeons now seem to feel that laminectomy and decompression is the treatment of choice in almost every case. It has been my own policy to recommend that laminectomy be performed early in every case of paraplegia that is caused by injury of the thoracic and lumbar spine. It is my opinion that early, routine laminectomy in such cases is actually the conservative course of action and that it can be done safely and without causing any delay in the ultimate rehabilitation of the patient.

There are many reasons why laminectomy should be performed, some of which have already been enumerated in early reports. Very briefly, some of the reasons for laminectomy are as follows: 1. In the thoracic and lumbar region it is an operation that can be performed quickly, under local anesthesia if necessary, without interfering with the stability of the spinal column and with a mortality rate that is practically nil. 2. There is no way during the immediate post-traumatic period in patients demonstrating complete paraplegia to ascertain, by either neurological examination or roentgenographic examination, whether there has been an anatomic transection of the spinal cord. An examiner is not justified by either clinical examination or roentgenologic examination in concluding that the spinal cord has been irreparably damaged. The only way one can determine early, in patients demonstrating complete loss of motor and sensory function, whether the spinal cord is anatomically transected is by direct exploration. Therefore, the patient should not be denied laminectomy because the examiner has the impression that the spinal cord is already hopelessly injured. 3. It can be considered that in some cases the removal of depressed laminas and other post-traumatic fragments of bone as well as intraspinal hematomas may have a beneficial effect upon future spinal cord function. 4. Wide débridement with intradural exploration may help to prevent late arachnoiditis and other later complications, such as pain and spasticity. 5. If wide decompression of the injured area of the spinal cord is performed shortly after injury, early mobilization and rehabilita-

---

Read in the Panel Discussion on Rehabilitation of Patients with Paraplegia before the Section on Physical Medicine at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

tion may be instituted more safely than if the patient still has spinal cord compression. 6. Paraplegic patients logically conclude that direct exploration and decompression of the spinal cord should be attempted, if there is not some definite medical contraindication, before they are asked to resign themselves to a lifetime of paraplegia and a long period of rehabilitation for their paralyzed extremities.

Alleviation of Sequelae

During the late phases of care for the patient with spinal cord injuries, that is, from three months to several years after injury, the neurosurgeon may be able to play a role in alleviating some of the undesirable sequelae of paraplegia. For the purpose of this discussion, I shall limit myself to two of the most intractable and distressing complications of spinal cord injury, pain and spasticity. Although these phenomena are not both invariably present in the same patient, there is some justification for considering pain and spasticity simultaneously. Both of these phenomena are paradoxical neurological sequelae of spinal cord injury. In the case of pain, this sensation is usually referred to areas rendered anesthetic and analgesic by the spinal cord lesion, so that heightened pain sensation is present in an area from which the application of painful stimuli cannot be appreciated. Likewise, spasticity in patients with paraplegia reflects exaggerated involuntary motion of muscles that cannot be moved voluntarily. Thus, these phenomena, namely, pain referred to analgesic areas and exaggerated activity in paralyzed muscles, are considered to be physiologically related. Moreover, in evaluating the etiology of these distressing sequelae, there is considerable evidence that not only the destructive elements of traumatic lesions but also the irritative effects of such injuries must be taken into account. For these reasons, pain and spasticity may be considered together.

Management of Pain.—Approximately 75% of the patients who incur spinal cord injury will, at some time during their course, complain of some type of severe pain. Because of the nature of such an injury, which may render a large part of the body numb, pain in these patients is particularly difficult to evaluate. No single classification of pain in paraplegic patients has been suggested that can be considered inclusive. Moreover, an etiological classification is not feasible at this time, inasmuch as the individual roles of the sympathetic nervous system, spinothalamic tract systems, and unrelated pathways have not yet been elucidated in these cases. Since there are some obvious differences in the mechanisms productive of pain during the early weeks after injury and those productive of pain after this period, it is well to consider pain early and late after spinal cord trauma.

Early Pain: A surprisingly small percentage of patients complain of severe pain over the site of vertebral injury. Many vertebral fracture-dislocations are unattended by local pain. In my experience, local discomfort is more common in cases of cervical fracture-dislocation than in fractures in other regions of the vertebral column. The treatment dictated by consideration of spinal cord lesion, as outlined earlier (that is, early skeletal traction in cases of cervical lesions and early laminectomy in cases of thoracic or lumbosacral lesions), will invariably alleviate the pain produced by the bony abnormality. In the cases in which spinal fusion is indicated, this procedure will also lessen the likelihood of prolonged local pain. Consequently, local pain over the site of vertebral fracture seldom becomes intractable and is usually managed without difficulty.

The two common neurological causes of pain in the nerve root are cartilaginous compression and complete intraspinal subarachnoid block. The presence of a complete subarachnoid block, particularly in the lower thoracic or lumbar region, will often produce severe pain in both lower extremities. This pain is often sharp and lancinating in character, as well as constant and excruciating. It may be diffuse throughout the extremities. It is sometimes accompanied by burning paresthesias. The pain is aggravated by extension of the back, coughing, sneezing, or other activities that tend to increase intra-abdominal and thus intraspinal pressure. Roentgenologic examination may provide evidence of narrowing of the intraspinal canal, and the presence of a subarachnoid block is confirmed by spinal puncture with careful manometric studies. Once this block is demonstrated, early laminectomy with decompression of the block is indicated. Surgical decompression will usually result in prompt relief of pain due to this cause. Since the presence of an intraspinal block is in itself indication for laminectomy, further discussion of pain due to such a cause is not necessary.

Pain due to compression of one or more nerve roots even in the absence of an intraspinal block is not infrequent in cases of vertebral fracture-dislocation. Compression of such roots may be due to anterior dislocation of a fractured lamina, posterior dislocation of part or all of the body of a fractured vertebra, protrusion of bony fragments into an intervertebral foramen, or traumatic protrusion of an intervertebral disk. The occurrence of the latter phenomenon is more common than had formerly been thought and has been emphasized recently, particularly as a cause of neurological damage in the cervical region.

Radicular pain due to one of the afore-mentioned causes of nerve root compression is recognized by those qualities peculiar to root pain: 1. The pain follows the anatomic distribution of one or more nerve roots. 2. Paresthesias along the same distribution are not uncommon, particularly in cases of incomplete transection of the spinal cord. 3. The pain is aggravated by coughing, sneezing, or straining. 4. The pain is usually intensified at night after the patient has been in an extended or hyperextended posture for some time. 5. The pain is usually sharp and lancinating in character.

Careful neurological evaluation and roentgenologic study will usually indicate the site at which radicular compression is occurring. Roentgenographic demonstration of a fracture extending through one of the intervertebral foramens, an extreme narrowing of an intervertebral disk space, or an obvious bony abnormality may indicate the vertebral site of nerve root compression. In some instances, in the absence of such roentgenologic findings and in the absence of a subarachnoid block, contrast myelography may be utilized as an adjunctive aid in evaluating the site and cause of nerve root compression following spinal injury. However, this latter procedure is to be avoided in such cases whenever possible. Many spinal cord injuries are accompanied by subarachnoid or intramedullary hemorrhages, arachnoidal lacerations, and other types of lesions conducive to fibroblastic reaction. Superimposed upon such a nidus, the introduction of iodized oil (Lipiodol) or iophendylate (Pantopaque) may contribute to the development of an adhesive arachnoiditis. This is a common finding in cases in which exploration is done one or more years after injury, and such arachnoiditis is undoubtedly a contributing factor in production of the sequelae of spinal cord trauma.

Surgical exploration and decompression is the treatment of choice in cases of pain due to nerve root compression. Hemilaminectomy, foraminotomy, or removal of a protruded intervertebral disk, depending upon whichever proves to be indicated, will often relieve radicular pain. Treatment of this type of injury to the spinal cord or cauda equina will be more successful in those cases in which decompression is carried out early, before the pain has become constant and before the patient has become dependent on narcotics.

One other cause of pain in paraplegic patients during the early days following spinal cord injury is the presence of concomitant injuries to other body parts, such as a ruptured spleen or traumatic hemothorax. Such a category is too obvious to require further elaboration and is mentioned only for the sake of completeness. However, I have seen patients in whom extraspinal injuries had been overlooked because of the initial examiner's preoccupation with the major symptom of paraplegia. Vigilance in a complete physical examination obviates such errors.

Late Pain: Pain of an intractable nature is more often a complaint of the patient three or more months after injury than during the early post-traumatic period. This pain has been classified by several authors. Most writers seem agreed that pain in the lower extremities may be of an intermittent, sharp, lancinating, radicular quality; a diffuse, dull aching quality; or a burning causalgia-like quality. The first type is most frequently seen in cases of injury to the cauda equina, while the second type is more commonly encountered in injuries of the spinal cord proper. The diffuse burning type of pain may be present in cases of injury to either the spinal cord or the cauda equina. Although the burning pain complained of by persons with paraplegia is similar to that usually described as causalgic, this type of pain in paraplegic patients is seldom, if ever, entirely relieved by sympathectomy. Holmes postulated that such persistent burning pain might be due to changes in the anterolateral columns of the spinal cord. Förster's investigations demonstrating that the entire pain pathway in the spinal cord is excitable substantiated Holmes' hypothesis. This still offers the best physiological explanation for the presence of diffuse aching, burning, tingling, or other nonradicular pains of the insensitive lower extremities of the paraplegic patient.

It has been my experience that all the categories of pain described in the preceding paragraph (that is, the radicular type of lancinating pains; diffuse, deep aching pain; or constant burning, tingling pains occurring in the insensitive paralyzed lower extremities), present three months or later after spinal cord injury, are best treated by bilateral high thoracic or cervical spinothalamic chordotomy. Like most neurosurgeons, I have had disappointing results with the use of spinothalamic chordotomy for pain in some paraplegic patients. However, if patients are selected who have not yet become addicted to narcotics and whose pain is not psychologically motivated, and if such patients are operated on under local anesthesia to allow instant appraisal of the level of analgesia achieved, the incidence of successful relief of pain will be reasonably satisfactory.

Relief of Spasticity.—In persons with traumatic paraplegia, spasticity of the paralyzed lower extremities becomes marked enough to impede rehabilitative measures in approximately 40% of those with injuries to the cervical and thoracic portions of the spinal cord. The relief of this spasticity will often enable a bedridden paraplegic patient to become ambulatory and self-sufficient. The four types of neurosurgical procedures that will alleviate intractable spasticity in the paraplegic patient are as follows: (1) peripheral neurectomy, (2) subarachnoid alcohol block, (3) rhizotomy, and (4) subtotal spinal chordectomy.

Peripheral Neurectomy: The resection of peripheral nerves has rather limited usefulness in relief of spasticity in paraplegic patients. It is confined largely to resection of the obturator nerves for relief of adductor, or scissors, spasticity. When the incapacitating spasticity is largely confined to the adductor muscles of the thighs, the procedure of choice is bilateral transabdominal obturator neurectomy. This procedure can be performed easily and provides immediate relief. The nerve is approached retroperitoneally through a McBurney abdominal incision and is readily identified as it emerges from the medial side of the psoas muscle to cross the brim of the pelvis. Stimulation of the nerve to produce adduction of the thighs positively identifies it prior to resection.

Subarachnoid Alcohol Block: Subarachnoid alcohol block has emerged as the single most useful and most applicable method available for relief of paraplegic spasticity. The indications for subarachnoid alcohol injection are essentially those previously applied to anterior rhizotomy. The chief indication is intractable spasticity of the lower extremities, which have no useful motor or sensory function. Enough time should have elapsed from the time of injury so that the lesion may be known to be stationary; this eliminates the possibility of future neurological recovery. This procedure has certain advantages over anterior rhizotomy: it is safer and more easily performed and is free of the hazards of major surgical procedure. Its effects are immediate and, in most instances, of long duration. It is, however, not selective. Thus, if certain nerve roots, such as those to the detrusor urinae, are to be excluded, this method is contraindicated in favor of selective anterior rhizotomy. Such contraindications, however, are rare, particularly since it has been demonstrated that satisfactory autonomic micturition and sexual potency in the male can develop after subarachnoid alcohol injection.

The technique of subarachnoid injection I now use is as follows: The patient is placed on his side in bed, and the foot of the bed is elevated 18 in. An 18-gauge spinal puncture needle is inserted at the first lumbar interspace. A syringe containing 15 cc. of dehydrated alcohol is attached to the needle, and the alcohol is injected at the rate of 1 cc. every 15 seconds. An assistant constantly checks the patient's vital signs and the level of anesthesia during the injection. The injection is continued until both legs have become completely flaccid or until 15 cc. of alcohol has been injected. The patient is then turned on his back and kept in this position for four to six hours. He is allowed out of bed on the following day. If the injection has not produced satisfactory flaccidity, it is repeated the following day, with an additional 10 cc. of alcohol being used.

Rhizotomy: Rhizotomy, or intraspinal resection of nerve roots, is the time-honored method of relieving paraplegic spasticity, used since the introduction by Förster of posterior root section for spastic paraplegia. The fact that posterior rhizotomy alone did not provide adequate relief of spasticity led Munro to develop the technique of anterior dorsolumbar rhizotomy. This method requires laminectomy and division of all anterior nerve roots from the 10th thoracic through the 1st or 2nd sacral. The last firm dentate ligament is usually regarded as indicating the level of the first lumbar nerve root, although this relation is not invariable. If one is anxious to avoid sacrificing the motor supply of the detrusor urinae (usually the second and third sacral roots), these roots can be positively identified by stimulating each sacral root individually and at the same time recording the intravesicular pressure. Unless one is desirous of sparing certain nerve roots, such as those which innervate the urinary bladder, or unless some sensation exists in the lower extremities, subarachnoid alcohol injection is probably to be preferred to anterior rhizotomy.

Subtotal Spinal Chordectomy: Occasionally one is faced with the problem of recurrent spasticity after subarachnoid alcohol injection. In these circumstances the operation of anterior rhizotomy is made very difficult by the dense adhesive arachnoiditis produced by the prior alcohol injection. This arachnoiditis usually makes positive identification of individual roots impossible. In such cases, one may resort to subtotal resection of the spinal cord. This subtotal chordectomy involves resection of the spinal cord and nerve roots below the level of the 9th or 10th thoracic segment. The operation requires a laminectomy extending from the 9th or 10th thoracic to the first lumbar level and is performed more quickly and easily than is anterior dorsolumbar rhizotomy. McCarty has demonstrated that removal of the entire cord in man below the second thoracic level is not incompatible with life. In my experience, removal of that section of the spinal cord below the ninth thoracic level has had no untoward or unexpected sequelae.

Summary

During the early management of the patient with spinal cord injury, the neurosurgeon may contribute to the neurological evaluation. He may perform skeletal reduction of cervical fracture-dislocation and laminectomy as well as decompressive procedures when these are indicated. The principal sequelae that often require the attention of neurosurgeons during the later phase of this problem are intractable pain and spasticity. There are various neurosurgical methods that may be utilized in the management of these sequelae.

REHABILITATION OF THE PARAPLEGIC PATIENT

Donald A. Covalt, M.D., New York

• *The end-result in rehabilitating the paraplegic patient is preparing him for a job, or at least preparing him for further vocational training that will result in a job. Total rehabilitation requires the cooperative services of the neurosurgeon, urologist, orthopedic surgeon, and physiatrist. The series of activities presented, which follow definitive care, are directed to the paraplegic patient's adjustment to walking and daily living.*

The rehabilitation of the paraplegic patient can only be accomplished with the closely knit cooperation of the neurosurgeon, urologist, orthopedic surgeon, and physiatrist. On admission, the patient should be taken directly to the x-ray room so that the neurosurgeon, having been called in to see him, can decide upon the advisability of surgery. The physiatrist should be called early to see the patient, who should be put on a Stryker frame or sponge-rubber mattress and turned every two hours. Particular attention should be paid to the skin over the sacrum and over the knees, as well as to that over the ischial tuberosities and the two trochanters. These areas should be cleansed carefully, massaged lightly, and oiled with some bland ointment or oil each time the patient is

Associate Professor, Department of Physical Medicine and Rehabilitation, New York University College of Medicine, and Associate Director, Institute of Physical Medicine and Rehabilitation, New York University—Bellevue Medical Center.

Read in the Panel Discussion on Rehabilitation of Patients with Paraplegia before the Section on Physical Medicine at the 105th Annual Meeting of the American Medical Association, Chicago, June 12, 1956.

turned. It is important that the patient be placed in a neutral anatomic position, and, if necessary, splints should be put on to preserve the right angle of the foot on the ankle.

The physical therapist should be given instructions about exercising the joints of the patient's paralyzed extremities through a complete range of motion. Also, the patient should be given exercise for stretching the Achilles tendon. While the patient is in bed, either waiting for a laminectomy or recuperating from the operation, he should be given exercises to strengthen the muscles of the upper extremities. These are the muscles that will help him to walk after he is given braces. Particular attention should be paid to the triceps and latissimus dorsi muscles

I do not recommend use of the triangular overhead bar, as some do, to aid patients in pulling themselves up into a sitting position, the patient only needs enough strength in the biceps to feed himself. Therefore, our patients are instructed to push themselves up with their hands placed behind them. This utilizes the triceps muscles and enables the patient to gain a sitting position. As soon as clearance is obtained from his neurosurgeon and/or orthopedic surgeon, the patient should be placed on a tilted board, with straps over his chest, hips, and knees, and should be allowed to stand in a vertical position. To start with, he should be allowed to stand at an angle of 25 to 30 degrees and only for a few minutes. This should be gradually increased, so that at the end of two weeks he should be standing in a vertical position for at least one hour a day. We know from research work that has been done[1] that an hour of standing a day will keep the calcium in the long bones of the legs and help to prevent urinary calculi and infection, which is the killer of paraplegic patients.

Braces should be ordered as soon as possible. We use as a rule of the thumb the 10th thoracic vertebra as a starting point. Those patients with lesions at T-10 and above are usually given double bar long braces with pelvic band and Knight spinal attachment for the back; those with lesions from T-10 to L-1 are given double bar long leg braces with pelvic band; and those with lesions below L-1, depending upon the musculature present, are given long leg braces.

Walking and Daily Living

The patient is brought to a standing position in the parallel bars and is usually started out with a "drag to" gait; he then advances to a "swing to" gait and, finally, a "swing through" gait. As soon as he is proficient in the parallel bars, the bars are eliminated and he is given crutches and taught to ambulate, at first with assistance and later by himself. The patient must be taught to climb curbs. We usually start with a 2-in. curb and graduate to a 4-in. curb and, finally, a 6-in. curb. Next, the patient must be taught to climb stairs. This is ordinarily taught with a one-hand rail and one crutch, the patient being allowed to carry the other crutch.

Also, the patient must be given an intensive course in activities of daily living. This would include training in transfer activities such as those from the bed to the wheelchair and back again, from the wheelchair to the toilet and back again, and from the wheelchair to a standing position and back again. He must be taught how to dress himself as well as all personal hygiene activities. Last, but not least, the patient must be taught to drive his own car, utilizing some of the simple hand-control devices that can be installed very inexpensively. Bowel and bladder training is most important. Bowel function is controlled by means of careful diet and the use of glycerin suppositories every other day. The majority of our patients do develop an automatic bladder control. However, since many of these patients return to active lives, they must be protected by some type of rubber urinal.

While the paraplegic patient is finishing his physical restoration, it is important that vocational possibilities be explored. In that way, when the patient is ready to leave the rehabilitation center he will know that he is prepared either to go to a job or to take further vocational training that will result in a job.

Summary

The patient with paraplegia should be kept on an active rehabilitation program from the time he is admitted to the hospital until he is discharged. He should be taught to become as self-sufficient as possible. Vocational possibilities should be explored, so that he may return to a job as soon as possible or may go on to further vocational training. Early rehabilitation procedures help to prevent the complications to which these patients are so liable. Later, the program must become more active and should include training in ambulation with braces, wheelchair activities, and hyperdevelopment of the patient's remaining muscles.

Capillary Thrombosis.—Capillary thrombosis is observed in a number of conditions. Extensive involvement has been reported in a variety of diseases, such as rickettsial infections, disseminated lupus erythematosus, periarteritis nodosa, malignancy, aplastic anemia, and thrombotic thrombocytopenic purpura. The pathogenesis is as yet undetermined. Moschcowitz was the first to report an instance of thrombotic thrombocytopenic purpura, this he did in 1925. He believed the thrombi consist of agglutinated erythrocytes, and pointed out that there is no evidence of primary vascular disease. Altschule ascribed the lesions to damage to the vascular endothelium, with secondary deposition of platelets. Muirhead and associates reported one case in which there were extensive endothelial proliferation, "platelet" thrombi and simultaneous "glomerulitis." Gore suggested that the earliest prethrombotic lesion in thrombotic thrombocytopenic purpura is a swelling of the subendothelial hyaline material, followed by rupture of the endothelium, with deposition of platelets on the injured spot and formation of a bimorphic thrombus. Endothelial proliferation and organization of the thrombus would then take place, only to be followed by new depositions of platelets, bringing about thrombocytopenia. Two of his five patients had a leukemoid blood reaction. In most cases reported, a shift to the left, with immaturity, was noted in smears of peripheral blood, but leukemia was ruled out. The clinical picture is rather typical, although not specific for the condition.—K. O. Husebye, M.D., J. M. Stickney, M.D., and W. A. Bennett, M.D., "Platelet" Thrombosis in Leukemia, *Annals of Internal Medicine,* May, 1956.

ABO BLOOD GROUPS AND DISEASE

Joseph A. Buckwalter, M.D., E. Bruce Wohlwend, M.D., Donald C. Colter, M.D., Robert T. Tidrick, M.D.
and
Lloyd A. Knowler, Ph.D., Iowa City

• *The existence of an association between certain diseases and the ABO blood groups was investigated by studying the blood-type frequencies of 158 patients with pernicious anemia, 908 with gastric carcinoma, 1,839 with peptic ulcer, 866 with carcinoma of the breast, 395 with carcinoma of the lungs, 256 with carcinoma of the colon and rectum, 456 with leukemia, 327 with congenital anomalies, and 184 with ulcerative colitis, and comparing them with the blood-type frequencies observed in blood donors. The strongest association found concerned peptic ulcer; statistically significant associations also were found for gastric carcinoma and pernicious anemia. Patients with pernicious anemia were distributed between groups A and O in the ratio 1:0.78, while the control patients exhibited the ratio 1:1.10. So great a difference in a sample of this size would have been found as an accident of sampling less than 5 times in 100, and is therefore accepted as significant. The incidence of gastric carcinoma was also greatest in persons with blood type A; that of peptic ulcer was greatest in persons with blood type O. The data suggested, but did not suffice to prove, an association of blood group with pulmonary and mammary carcinoma. No evidence was found of association with carcinoma of the colon and rectum, leukemia, ulcerative colitis, or congenital anomalies.*

Although the first half of the 20th century has seen the rapid expansion of the science of genetics, there has not been comparable growth in that branch concerned with human inheritance. This is related to a long gestation period, small family size, and a scarcity of characteristics inherited in a sufficiently simple manner to make practical a study of the genetic mechanisms involved. Undoubtedly, the impossibility of bringing about experimental mating in humans has played a major part. The blood groups, however, provide the specialist in human genetics with an almost ideal tool for use in his studies. Being all-or-none characteristics, they are readily classified, and their method of inheritance is exactly known. A practical illustration of the latter is their use in paternity problems. That considerable thought has been given to the possibility of an association between the ABO blood groups and disease is indicated by the numerous reports since 1920. Most of the early studies were done elsewhere than the United States. The results of these investigations were conflicting and inconclusive. At the time of the comprehensive review by Lessa and Alarcao[1] in 1949, there still was no convincing evidence of such an association, although Levine, Katzin, and Burnham[2] in 1941 had demonstrated the role of rhesus blood types in erythroblastosis fetalis.

In 1951, Struthers[3] found that, in Scotland, there was an increased (higher than expected) frequency of blood type A among children dying of bronchopneumonia during the first two years of life. Widespread interest was kindled among geneticists, immunologists, general biologists, and clinicians by the report of Aird, Bentall, and Fraser Roberts[4] in 1953 indicating a highly significant increased frequency of blood type A and decreased (lower than expected) frequency of blood type O among 3,632 patients with gastric cancer in England and Scotland; similar findings were subsequently reported by Hollander[5] from Switzerland, Køster, Sindrup, and Seele[6] from Denmark, and our group[7] from the United States. In 1954, Aird and co-workers[8] reported data indicating an even more highly significant association with peptic ulcer characterized by an increase in O and decreases of the other blood-type frequencies in 3,011 patients. These findings were confirmed by Clarke and associates[9] in Great Britain, Køster, Sindrup, and Seele[6] in Denmark, and our group[10] in the United States. However, our results indicated no significant difference between duodenal and gastric ulcer, whereas the other investigators obtained dissimilar findings for the two; gastric ulcer did not show the highly significant increase in type O and decrease in type A noted for duodenal ulcer.[9] McConnell, Pyke, and Fraser Roberts[11] have found a significant increase in frequency of blood type A in male patients with diabetes mellitus in England, which they feel merits only a tentative conclusion of an association; there was no evidence of a similar association in women. Likewise, there does not appear to be an association to age of the patients, as was earlier suggested.

The failure of earlier studies to demonstrate the existence of the now-noted associations may be explained by the small size of the series, absence of disease specificity with regard to patient groups studied, unsatisfactory controls, and the failure to use proper methods of statistical analysis. However, since these considerations have been appreciated, in addition to the positive findings discussed above, the results of other, negative investigations have been reported. From England, in 1954, Aird and others[8] reported no association for carcinoma of the colon and rectum (2,599 cases), breast (1,017 cases), and bronchus (998 cases); McConnell, Clarke, and Downton,[12] in 1954, reported none for 777 cases of carcinoma of the lung. The initial evidence of an association of the ABO blood groups to toxemia of pregnancy has not been supported by later data collected by the same authors and Dickins and co-workers.[13] In 300

From the Department of Surgery, College of Medicine, and the Department of Mathematics and Astronomy, State University of Iowa.

Read before the Section on Preventive and Industrial Medicine and Public Health at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

cases of gynecologic cancer, Krokfors and Kinnunen[14] in Finland in 1954 were unable to find evidence of an association. Maxwell and Maxwell[15] in 1955 reported their findings indicating no association in 2,147 patients with essential hypertension in Scotland.

This report is concerned with the results of the investigations of the ABO blood-type frequencies in patients with several diseases at the State University of Iowa Hospitals. The authors of previous investigations done in the United States concluded there was no evidence for an association of the ABO blood groups and the diseases studied; these investigations are discussed in other communications.[16]

Clinical Material and Procedure

The case material was provided by patients seen at the University Hospitals, except for some of the cases of gastric carcinoma, peptic ulcer, and breast carcinoma, as will be indicated. To insure the high degree of homogeneity with regard to categories of disease vital to this study, only patients with ironclad diagnoses were included. Microscopic proof was required for the carcinomas, while unequivocal clinical findings were regarded as mandatory for other diseases. In addition to the diagnostic criteria, the only other factor acting to select cases was information concerning the patient's blood type. The case records of all patients with the various diagnoses made available by the record room files were reviewed and included if satisfying the two forementioned requirements. To eliminate possible errors resulting from collection by multiple investigators, we selected and recorded all the data. Innumerable statistical studies were made feasible by transferring the collected data to punch cards and then using machine methods for tabulation and sorting.

TABLE 1.—*Blood-Type Distribution in Groups Studied*

Blood Type	A University Hospitals Donors		B Des Moines Donors		C Controls*		D University Hospitals Patients†	
	No.	%	No.	%	No.	%	No.	%
O	2,149	45.8	743	45.8	2,892	45.8	1,124	45.8
A	1,953	41.7	672	41.4	2,625	41.6	1,000	40.8
B	423	9.0	147	9.1	570	9.0	246	10.0
AB	165	3.5	61	3.7	226	3.6	84	3.4
Total	4,690	100.0	1,623	100.0	6,313	100.0	2,454	100.0

* Combined data (col. A and B).
† Patients with peptic ulcers or neoplasms excluded.

TABLE 2.—*Blood Types in Controls and in Patients with Pernicious Anemia*

	Type O	Type A	Type B	Type AB	Total
Pernicious anemia	59	76	14	9	158
Controls	2,892	2,625	570	226	6,313
Totals	2,951	2,701	584	235	6,471

The procedure employed in analyzing the data was to compare the blood-type frequencies noted in groups of patients with those observed in a normal population sample. Healthy blood donors who were friends and relatives of the patients and who came from the same geographical area and had similar ethnological and anthropological origins were used. In table 1 are recorded the data collected by tabulating the blood types of consecutive blood donors at a Des Moines and the University Hospital blood bank. In column C are the combined data, which were used as controls for comparison with the blood-type frequencies noted in the patients. Note the close agreement of the blood-type frequencies of University Hospital patients receiving consecutive transfusions, excluding only those with diagnoses of peptic ulceration or malignancy, with those of the blood donors used as controls.

TABLE 3.—*Frequency of Types O and A in Patients with Pernicious Anemia and in Controls*

	O	A	Totals	Type A, %
Pernicious anemia	59	76	135	0.5630
Controls	2,892	2,625	5,517	0.4758
Totals	2,951	2,701	5,652	

The statistical significance of differences noted between the patients' and the controls' blood-type frequencies was tested by the chi-square method, which naturally weights the disease to match the size of the control group. An additional test in the form of the method of difference in percentages based upon the normal curve theory has been applied to the data at hand. In a consideration of the various methods of examining these data, comparison of the differences in the frequencies of the four blood types between patients and controls is the obvious and perhaps first one that should be applied. For example, let us examine all of the blood-type findings in the patient and control groups for pernicious anemia at the 5% level of significance (table 2). In this case chi square equals 6.772 with 3 degrees of freedom. Since the value of chi square at the 5% level of significance with 3 degrees of freedom is 7.815, we have a result that is not regarded as significant at the 5% level. However, we observe that $0.05<p<0.10$, and so it might be worthwhile to conduct an additional study involving more data or to examine these data in greater detail.

Since in the instance of each disease studied, more than 85% of the patients had blood type O or A, and since the major differences from the controls most often occurred in O and A, it was believed desirable to examine the data as to the statistical significance of the reciprocal changes in frequencies of the O and A blood types. This afforded an opportunity to compare the results with those of other investigators who for the most part have used this method of analysis.

TABLE 4.—*Blood Types in Patients with Gastric Carcinoma and Peptic Ulcer and in Controls*

	Blood Type O		Blood Type A		Blood Type B		Blood Type AB	
	No.	%	No.	%	No.	%	No.	%
Gastric carcinoma (908 cases)	383	42.2	416	45.8	84	9.2	25	2.8
Peptic ulcer (1,839 cases)	983	53.5	679	36.9	134	7.3	43	2.3
Controls (6,313 donors)	2,892	45.8	2,625	41.6	570	9.0	226	3.6

In particular, let us examine the frequencies with which types O and A occurred in the patients with pernicious anemia and compare them with the frequencies in the controls. The following 2 × 2 contingency table (table 3) states that among this total of 5,652 persons there were 59 who had pernicious anemia and whose blood was of type O. Calculations based on the subtotals show that, if there were no association between blood type and pernicious anemia, 65 patients would be expected to show this combination simply by chance, for 2,701 × 135/5,652 = 65 (approximately). But the figure actually found, namely, 76, exceeds the expected number by 11. The following calculation of chi square for a fourfold table (which has 1 degree of freedom) shows that so great a discrepancy between the actual and the expected would occur by chance less than 5 times in 100:

TABLE 5.—*Number of Patients with Carcinoma of the Breast by Blood Type and Hospital*

	Blood Type			
	O	A	B	AB
University Hospitals (571 cases)	244	253	56	18
Iowa Methodist Hospital (Des Moines) (138 cases)	57	63	9	9
Mercy Hospital (Iowa City) (157 cases)	69	67	16	5
Totals (866 cases)	370	383	81	32

$$X^2 = \frac{[(59)\,(2{,}625) - (76)\,(2{,}892)]^2\,(5{,}652)}{(2{,}951)\,(2{,}701)\,(135)\,(5{,}517)} = 4.012$$

From tables of chi square it can be seen that a value of 4.012 corresponds to a value of p between 0.02 and 0.05, and it can be asserted, therefore, that the frequency of blood type A was significantly higher among the patients with pernicious anemia than among the controls.

Further consideration based upon the difference in percentages based upon the normal curve theory:

$$t = \frac{0.5630 - 0.4758}{\sqrt{\dfrac{(0.5630)\,(0.4370)}{135} + \dfrac{(0.4758)\,(0.5242)}{5{,}517}}} = \frac{0.0872}{0.0477} = 1.83$$

yields a value that is slightly lower than that at the 5% level. However, any test that reveals a significant difference should not be overlooked. Consequently, this study suggests that the frequency of blood type A is significantly higher in patients with pernicious anemia than in the controls. In addition to the two methods illustrated, other comparisons taken two and three at a time (such as O and B or O and A and B) were made where indicated. Only the results of the first two comparisons will be reported.

TABLE 6.—*Blood Types of Patients with Carcinoma of the Breast*

Blood Type	Patients No.	Patients %	Difference in % from Controls	X^2	Level of Significance (Probability)
O	370	42.7	−3.1	2.861	$0.05 < p < 0.10$
A	383	44.2	+2.6	2.877	$p > 0.10$
B	81	9.4	+0.4		
AB	32	3.7	+0.1		
Total	866	100.0	0.0		

Results

The findings for patients with gastric carcinoma and peptic ulcer are summarized in table 4. When the blood-type frequencies noted in the patient and control groups were compared, levels of significance for the observed differences were noted at 2% for gastric carcinoma and 0.1% for peptic ulcer. The detailed data and discussion concerned therewith are included in other articles.[16] In table 5 are recorded the data, collected from three hospitals, relative to carcinoma of the breast. No significant differences were found between the blood-type frequencies of the patients from the different hospitals. For purposes of the further statistical analysis, these data were combined. The results of the O-A and the O-A-B-AB comparisons are recorded in table 6. Of interest is the chi-square value for the O-A comparisons indicating a level of significance at 10%, as compared with the O-A-B-AB comparison, where there was no evidence of significance.

Patients with carcinoma of the lung were studied as one sample and were not subdivided by cell type. As will be noted in table 7, the O-A comparison was significant at the 5% level. That is, the observed discrepancy between the expected and the actual would arise by accidents of sampling 5 times in 100. That it did so arise seems the more likely when one notices that, in the examination of the entire group, the differences among the four types could have arisen by chance 10 times in 100 and are therefore not to be considered significant. This may be due to the fact that the slightly increased AB and decreased B frequencies in the patients as compared with the controls balanced one another. The data with regard to patients with carcinoma of the colon and rectum appear in table 8. No evidence of statistical significance was discovered when comparisons of the O-A or the O-A-B-AB differences were made. When colonic (153 cases) and rectal (103 cases) carcinoma were examined separately, likewise no evidence of an association to blood type was found.

TABLE 7.—*Blood Types of Patients with Carcinoma of the Lungs*

Blood Type	Patients No.	Patients %	Difference in % from Controls	X^2	Level of Significance (Probability)
O	202	51.1	+5.3	4.643	$0.02 < p < 0.05$

Total	256	100.0	0.0		

Although most of the leukemias studied were either lymphatic or myeloid in type, small numbers of the less common ones were included. No evidence of an association to the ABO blood groups was found (table 9). The congenital anomalies studied have included those of the nervous, cardiovascular, respiratory, genitourinary, and gastrointestinal systems. Inspection of the combined data recorded in table 10 indicates that no statistically significant differences were found. Study of each separate group failed equally to show evidence of statistically significant differences. No evidence was found to suggest an association between the ABO blood groups and ulcerative colitis. These data are recorded in table 11. Although relatively few cases were available for study, evidence suggesting an association to the ABO blood groups, as already illustrated, was found in patients with pernicious anemia. These data are recorded in table 12. It will be noted that the evidence was strongest when the O and A comparison was made.

Comment

In the evaluation of the results of this or any similar study, reliable controls have been regarded as most important. This reliability is determined by whether or not the controls are truly representative of the population from which the patients came. For reasons stated in another article,[10] our controls would seem to compare favorably with those used by the other authors. The possible existence of unrecognized factors acting to select blood donors and thus altering the results of the comparisons with control patients has been considered. Whether blood donors are satisfactory controls and whether the concept of normal population controls for these investigations is valid are two questions not finally answered, which are the subject for continuing study.

TABLE 9.—*Blood Types of Patients with Leukemia*

Total	327	100.0	0.0		

As mentioned before, rigorous diagnostic criteria must be insisted on in categorizing patients for study. Patients who could not be regarded as having ironclad diagnoses were rejected. Pernicious anemia presented a particularly good example of this point. Although more than 600 cases were noted in the record-room files, only 158 of these patients were judged to have ironclad diagnoses, with achlorhydria, macrocytic hyperchromic anemia, megaloblastic bone marrow, and proper response to therapy. Absence of information relative to blood type eliminated a substantial number of patients.

The findings in gastric carcinoma agree with those reported by Aird, Bentall, and Fraser Roberts,[4] Hollander,[5] and Køster, Sindrup, and Seele.[6] Similarly, with the exception of the previously indicated difference in regard to gastric ulcer, our findings in peptic ulcer are in accord with those reported by Aird and co-workers,[8] Clarke and associates,[9] and Køster, Sindrup, and Seele.[6] Aird and co-workers [8] found no significance in the differences of the blood-type frequencies between controls and patients with carcinoma of the breast. Our finding indicating an increase in type A frequency of a level of significance at 10% for the O and A comparison is not to be interpreted as conclusive evidence of an association between mammary carcinoma and the ABO blood groups. It will be interesting to observe the results of future studies of this kind.

TABLE 11.—*Blood Types in Patients with Ulceratice Colitis*

Blood Type	Patients No.	Patients %	Difference in % from Controls	X^2	Level of Significance (Probability)
O	80	43.5	−2.3	0.552	$p > 0.10$
A	82	44.6	+3.0	0.773	$p > 0.10$
B	15	8.1	−0.9		
AB	7	3.8	+0.2		
Total	184	100.0	0.0		

A similar situation exists for lung carcinoma, for which Aird and associates [8] and McConnell, Clarke, and Downton [12] found no data of statistical significance. There is a need for study of more cases before proper interpretation at the 5% level of significance found for the O and A comparisons may be made. It is of interest that here, as in mammary carcinoma, comparison of the four blood-type frequencies rather than just O and A showed no statistically significant differences, the rather large differences in O and A frequencies being neutralized by absence of differences for types B and AB. In our series, 12.5% of 348 patients were Rh negative as compared with 15.7% of the controls; this difference is not statistically significant. There is an obvious need for collection of more data regarding this point.

TABLE 12.—*Blood Types of Patients with Pernicious Anemia*

Blood Type	Patients No.	Patients %	Difference in % from Controls	X^2	Level of Significance (Probability)
O	59	37.3	−8.5	4.012	$0.02 < p < 0.05$
A	76	48.1	+6.5	6.722	$0.05 < p < 0.10$
B	14	8.9	−0.1		
AB	9	5.7	+2.1		
Total	158	100.0	0.0		

The failure to find any evidence of significance for the differences observed in colonic and rectal carcinoma, leukemia, ulcerative colitis, and in patients with congenital anomalies, although not excluding the possibility of an association between these diseases and the ABO blood groups, makes it seem unlikely. In view of the similar findings of Aird and others [8] for carcinoma of the colon and rectum, the possibility of such an association in these disorders seems most unlikely. The findings reported by Tinney and Watkins,[13] in

1941, support the absence of any statistical significance for the data concerning leukemia. We are unaware of other similar data pertaining to ulcerative colitis or congenital anomalies.

Because of the heretofore recognized relationship between gastric carcinoma and pernicious anemia,[18] it is of a particular interest to note that evidence exists of an association to the ABO blood groups characterized by an increase in type A and decrease in type O frequency. These findings are in accordance with those of Aird [19] and differ from those of Køster, Sindrup, and Seele.[6] The implications of the association of pernicious anemia, gastric cancer, and the ABO blood groups, in view of the evidence of the role of heredity in gastric cancer,[20] are interesting and merit further investigation.

The level of statistical significance for the differences in the blood-type frequencies between the groups of controls and patients is a function of the size of that difference and the number of patients available for study. This latter factor has played a major role in our investigations, the size of our series of patients being limited by the number of patients (1) satisfying the diagnostic criteria and (2) for whom blood-type information was available. In the instance of each disease studied, with the possible exception of duodenal ulcer, it would have been desirable to have had more cases. However, from a practical point of view it is apparent that the investigator in the instance of each disease can have only a finite number of cases. Although the results based upon a relatively small number of cases are often inconclusive, two purposes may be served in reporting them. The findings may indicate the need for collection of more data or, when they are added to series already collected, may result in convincing evidence of a previously suspected association. Conversely, a previously suspected association may be made less acceptable. A real danger exists, however, of drawing unwarranted conclusions from series of insufficient size, serving thereby to confuse and discredit these researches.

The findings concerning gastric cancer, peptic ulcer, and pernicious anemia support the attractive hypothesis of a relationship between the ABO blood groups and the pathological physiology of the stomach and duodenum in these patients. The evidence of a relationship to the secretion of free hydrochloric acid [10] fits nicely with this concept. It remains to be proved that ulcerogenic and carcinogenic or, conversely, protective attributes are exercised by the mucopolysaccharide blood group substances.

The evidence of associations for diseases not related to the gastrointestinal tract suggests that the association of blood group and disease may be related to broad anatomic, biochemical, and physiological considerations, thus relating disease and heredity. A possible role in natural selection is suggested for the ABO blood groups by these findings. Whether these and other speculations have basis in fact must await the collection of more data, with careful adherence to the criteria that have been established, and the results of basic investigations of the underlying mechanisms. Although the possibility that the findings merely indicate a chance association between the ABO blood groups and disease rather than a causal relationship becomes less likely with the report of each group of data confirming the association, the former possibility has not as yet been excluded. Likewise, an anthropological explanation based on the possibility that there are population strains with high or low incidences of certain diseases becomes progressively less tenable with the accumulation of similar data from different population groups throughout the world.

Summary

Conclusive evidence of an association between the ABO blood groups and disease has been found. Gastric carcinoma occurs more frequently in persons with blood type A than in those with the other blood types, peptic ulcer more frequently in those with blood type O, and pernicious anemia more frequently in those with blood type A. No evidence of such an association was found in patients with carcinoma of the colon and rectum, leukemia, ulcerative colitis, or those with congenital anomalies. In cancer of the lung and breast, more data will need to be collected before the equivocal findings may be properly interpreted; in view of the failure of other investigators to find evidence for an association, much more convincing data must be collected before the possibility of associations for these diseases may be claimed.

Addendum

Since this article was submitted for publication, in addition to the associations for gastric carcinoma and pernicious anemia we have found evidence of associations between rheumatic heart disease, hip fracture, and the ABO blood groups. Evidence has also been found of similar associations in a Negro population group.

This study was supported in part by a grant from the American Cancer Society.

PEPTIC ULCERATION AND ABO BLOOD GROUPS

Joseph A. Buckwalter, M.D., E. Bruce Wohlwend, M.D., Donald C. Colter, M.D., Robert T. Tidrick, M.D.
and
Lloyd A. Knowler, Ph.D., Iowa City

• *The incidence of the four blood types O, A, B, and AB was studied in 1,301 patients with duodenal ulcer, 469 with gastric ulcer, and 69 patients with both gastric and duodenal ulcers. The three distributions so obtained were compared with the distribution found in a reference of 8,767 people without ulcers. Type O was more frequent among the ulcer patients than in the reference group, and calculations of probability showed that the association between type O and peptic ulcer was statistically significant. It was shown not to be secondary to any influences of sex, age, rhesus blood type, or occupation. Among a group of 529 patients who had histamine tests, however, the frequency of type O was significantly greater among those who reacted with an increase of free hydrochloric acid than among those in whom no increase of acid occurred.*

In 1921, 21 years after Landsteiner's [1] classic blood-group work, Buchanan and Higley [2] reported a study of the possible relationship of the ABO blood groups to various diseases, including peptic ulceration. These authors concluded that there was no relationship to any disease for which sufficient data were available to justify a conclusion. The data reported by Ugelli [3] in 1936 and Lessa and Alarcao [4] in 1949 show an increased (higher than expected) frequency of blood type O in patients with peptic ulcer. The failure to recognize the significance of these data may be attributed to the difficulty in obtaining suitable population control groups, a preoccupation with the study of multiple diseases, the small size of the series, and a failure to apply suitable methods of statistical analysis. In 1954, Aird and co-workers [5] demonstrated convincingly that a highly significant relationship exists between peptic ulceration and the ABO blood groups in Great Britain. Their data indicate that persons with blood type O are about 35% more likely to develop peptic ulceration than are those with the other types. Similar findings have since been reported by Clarke and associates [6] from Liverpool and Køster, Sindrup, and Seele [7] from Denmark.

The initial effect of these observations has been to give interested clinical and basic investigators alike a sense of fulfillment of the expectation, based on genetic considerations, that the relationships between diseases and blood groups that should exist, do in fact. Ford [8] hinted at this in suggesting the possible relationship of blood groups to natural selection. It is possible that a door has opened through which a way may be seen to further research leading to the solution of heretofore unfathomable problems related to the broad considerations of disease and heredity. As yet, satisfactory explanations for the observed phenomena have not been provided. The immediate need is for the collection of similar data from other population groups throughout the world. The present report concerns such investigations carried out in the United States; the authors of two previous reports from this country concluded that there was no association between the ABO blood groups and peptic ulceration.[9]

Materials and Methods

The bulk of the clinical material for this study was provided by patients admitted to the University Hospitals from 1940 to 1956. Five other Iowa hospitals provided the remainder. Data obtained from the Iowa City and Des Moines blood banks have been used to determine the frequency of blood types in the population from which the patients came. Since the percentage of Negroes among the blood donors did not differ significantly from the 2.1% noted among the otherwise Caucasian patient groups, race did not contribute to the observed differences in blood-type frequency. In table 1, columns A and B, are recorded the number of individuals of each blood type and the percentage of the total group this number represents (subsequent-

---

ly referred to as blood-type percentage). Since there were no significant differences noted between the Iowa City and Des Moines donors in regard to the ABO group frequencies, they have been pooled and are henceforth referred to as controls (column C). A further indication of the reliability of these donor groups as representative population samples is provided by a comparison of the blood-type frequencies noted with those of a random sample of patients at University Hospitals, with only those with peptic ulcer and neoplastic disease excluded (table 1, column D). Statistical analysis of these data has been completed by methods to be described.

TABLE 1.—*Blood-Type Distribution in Groups Studied*

Blood Type	A University Hospitals Donors		B Des Moines Donors		C Controls*		D University Hospitals Patients†	
	No.	%	No.	%	No.	%	No.	%
O	2,149	45.8	743	45.8	2,892	45.8	1,124	45.8
A	1,953	41.7	672	41.4	2,625	41.6	1,000	40.8
B	423	9.0	147	9.1	570	9.0	246	10.0
AB	165	3.5	61	3.7	226	3.6	84	3.4
Total	4,690	100.0	1,623	100.0	6,313	100.0	2,454	100.0

* Combined data (Col. A and B).

† Patients with peptic ulcers or neoplasms excluded.

To ensure reliability of the data, it was essential to establish sound diagnostic criteria, which were then painstakingly applied in the selections of the cases. Either an anatomic or an ironclad clinical diagnosis of peptic ulcer was required. *In the patients with* anatomic diagnoses, comprising more than 80% of the clinical material, the diag*nosis was established* at the time of operation by gross and/or microscopic findings. The surgeon's operative note and pathologist's reports were the source of this information. Differentiation of duodenal from gastric ulcer was similarly determined; a third group of patients having both duodenal and gastric ulcers was included. Patients having lesions located at the pylorus, in whom it was impossible to determine whether the ulcer was duodenal or gastric, were excluded. By ironclad clinical diagnosis is meant a convincing history and positive evidence of ulcer on radiological and/or gastroscopic examination.

TABLE 2.—*Type of Ulcer, Blood Type, and Hospital of Patients Studied.*

* Data from Iowa City and Des Moines veterans hospitals combined.

To eliminate possible errors resulting from collection by multiple investigators, a team composed of three of us (E. B. W., D. C. C., and J. A. B.) selected and recorded all the data. On a separate card for each patient was recorded the desired information culled from the patient's case record. This included the following: identifying information, age, year seen, sex, race, occupation, primary and secondary diagnoses, method of diagnosis and treatment, gastric acidity, histamine-test response, Rh blood type, and, most important, the ABO blood group. Innumerable correlation studies were made feasible by the transference of the collected data to IBM punch cards and the use of machine tabulation and sorting methods.

TABLE 3.—*O-A and O-A-B-AB Comparisons for All Patients with Ulcer*

Ulcer	Blood Type	Patients: No.	Patients: %	Difference in % from Controls	X^2	Level of Significance (Probability)
Duodenal	O	698	53.7	+7.9	20.340	$p<0.001$

	AB	43	2.3	−1.3		
	Total	1,839	100.0	0.0		

The only factors affecting case selection were our diagnostic criteria and the availability of blood-typing information. Through the record room files of the respective hospitals, the records of all patients with a diagnosis of peptic ulcer were scrutinized. Only one in six patients with a clinical diagnosis met our requirements and could be included in the study. In examination of the data, comparison has been made of the frequency of each blood type observed in the disease and control samples. The statistical significance of observed differences has been tested by the chi-square method, which naturally weights the disease to match the size of the control group. Aird and co-workers[5] have amply discussed the importance of this latter calculation in making most efficient use of the data at hand. The validity of the analyses has been further tested by application of the method of differences in percentages based upon the normal curve theory.

Results

In table 2 are recorded the numbers of patients, tabulated by hospital and lesion, with each blood type. Comparison of the data collected from the individual hospitals, with the exception of the University Hospitals, would appear to be meaningless because of the small numbers of patients. No significant degree of heterogeneity was shown to exist between the hospital groups. Therefore, in the further examination of the data, those data from the six hospitals have been combined and are considered as one sample.

TABLE 4.—*Blood Types O and A with Reference to All Patients with Ulcers and to Controls*

	Blood Type			
	O	A	Totals	Type O, %
All ulcers	983	679	1,662	59.15
Controls	2,892	2,625	5,517	52.42
Totals	3,875	3,304	7,179	

The blood-type frequencies observed in patients with duodenal, gastric, and both ulcers were compared with those of the controls. For those who desire to do so, gene frequencies may be calculated by Fisher's method as described by Dodson and Ikin,[10] which is merely another way of presenting the data *showing the same relationships*. In table 3 are recorded the numbers of patients with each blood type by lesion, blood-type percentages, the increase or decrease of blood-type percentage of the disease as compared with the control group, chi-square values for the O-A and the O-A-B-AB comparisons, and the levels of significance indicated. A reciprocal difference is observed in the relative portions of the O and A types. When the data were analyzed by O-A, O-A-B, O-A-B-AB comparisons, etc., it became apparent that the simplest, most practical method of analysis was to study the significance of the reciprocal changes noted in the O and A blood-type frequencies. This is because the greatest discrepancies occur in blood type O and also because about 85% of the patients have either O or A blood type. Since this type of analysis has been used by previous workers, it also affords an opportunity to compare our results with those of similar studies being reported from different areas of the world. Since the other comparisons added little interest to the present discussion, only two results are recorded in the table, namely (1) the relative frequencies of types O and A and (2) the relative frequencies of types O, A, B, and AB.

For an example, suppose we examine the relationship of the blood types O and A with respect to ulcers of all types (table 4).

The calculation (1,662)(3,875)/7,179=897 shows that, if there were no relationship between blood group and ulcers, in a sample of this size one would expect to find ulcers in 897 patients of type O, purely as a matter of chance. In reality there were 983. The difference between the actual and the expected figures is therefore 86. The probability that so great a difference might occur simply as an accident of sampling is found by the following computation of chi square:

$$X^2 = \frac{[(983)\ (2,625) - (679)\ (2,892)]^2\ (7,179)}{(1,662)\ (5,517)\ (3,875)\ (3,304)} = 23.26$$

A 2 × 2 contingency table has one degree of freedom. From tables of chi square one obtains, for 1 degree of freedom and a chi-square value of 23.26, a value of p less than 0.0005. This means that it is extremely unlikely that the above difference arose purely by chance; the difference is highly significant. We therefore assert that the incidence of ulcers of all kinds was significantly higher in patients with type O than type A blood, or that the incidence of type O among patients with ulcers of all kinds was higher than among the controls. This result is confirmed by the use of method of differences in percentages based upon the normal curve theory:

$$t = \frac{0.5915 \quad - \quad 0.5242}{\sqrt{\frac{(0.5915)\ (0.4085)}{1,662} - \frac{(0.5242)\ (0.4758)}{5,517}}} = \frac{0.0673}{0.0138} = 4.88$$

which again is highly significant since the value of t is greater than 3.

Notice that differences of the greatest magnitude, similar for each of the patient groups, occurred with regard to blood type O. Note the negative differences of lesser magnitude for the other three blood types in each group of patients. Disparity in the size of samples of patients is chiefly responsible for the differing levels of significance (probability) for the three groups, and it is possible that, if a comparable number of patients with gastric or both gastric and duodenal ulcers had been available, significant differences comparable to that for duodenal ulcer might have been observed. In the succeeding treatment of the data concerned with the specific characteristics of the groups of patients, the patients with duodenal, gastric, and both

TABLE 5.—*O and A Blood Types with Regard to Various Factors*

Row	Factors	Patients No.	Blood Type	Patients No.	Patients %	Difference in % from Controls	X^2	Level of Significance (Probability)

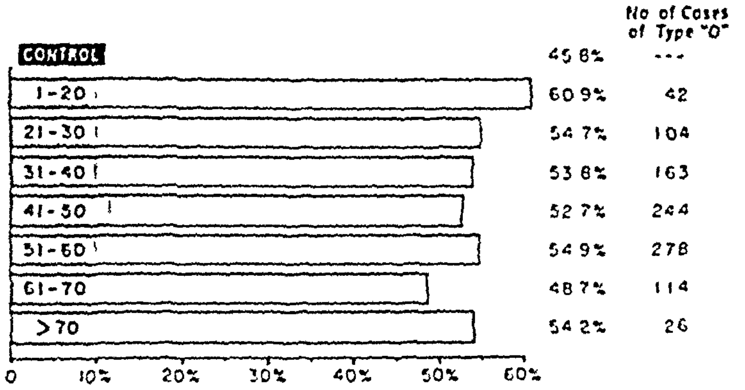
			A	51	44.3	+2.8		

ulcers have been combined and are considered as one sample. This was desirable not only because it simplifies the presentation but also because the possibility that a statistically significant relationship would be missed as a result of insufficient numbers of patients in a sample was thus reduced. When indicated, independent analyses for each group were done.

In view of findings that indicated an association between peptic ulcer and the ABO blood groups, it became important to explore the possibility that certain characteristics of these patients might have a relationship to the demonstrated association. Such a relationship would offer additional support for the main association and might provide a promising approach leading ultimately to an understanding of the causes responsible. In table 5 are recorded the data relative to Rh blood types, sex, methods of diagnosis, treatment, and gastric acidity. The numbers of patients for whom such information was available are indicated; in none of the categories studied was such information obtained for all 1,839 patients with ulcers. Here, likewise, the reciprocal changes in O and A frequencies were employed in analysis of the data.



Percentage of patients with peptic ulcer with blood type O, by decade of age. The frequency of type O among patients of all ages was 53.5%, while it was 45.8% for the controls.

Changes in B and AB frequencies were as expected; the analyses of the B and AB changes added nothing to our present considerations and are not recorded.

Of the 1,473 patients in whom the Rh blood type was determined, 1,228, or 83.4%, were Rh positive; when this was compared with the 84.3% noted in the controls, no significant difference was found. When the same analysis was performed for each blood type, i. e., comparison of positive and negative in patients and controls with blood type O, etc., no significant difference was found. These data were examined in another way in row 1, where the ABO blood-type frequencies noted within the positive and negative groups were compared; again, no significant difference was demonstrated. It may be concluded that Rh type appears to have no relationship to the ABO blood group–peptic ulcer association.

With those from the two Veterans Administration hospitals excluded, there remained 1,472 patients, of which number 1,194, or 81.1%, were men. Row 2 shows that there was *no significant* relationship between sex of the patient and the ABO blood group–peptic ulcer association. As has been stated, in addition to the bulk of patients with diagnoses established at the time of surgery, those with ironclad clinical diagnoses were included. Although comparison of these two groups, in row 3, indicates a higher frequency of blood type O in those patients with surgical diagnoses, no significant difference was demonstrated. Likewise, none was found when patients treated with and without surgery were compared (row 4).

Information concerning gastric analysis, specifically that concerned with free hydrochloric acid, was obtained for 804 patients. After scrutinizing the data regarding degrees of free acid, we decided that the most meaningful method of analysis was to compare those patients with decreased or negligible amounts of free acid and those with normal or increased amounts. Row 5 shows that the apparent differences in blood-type frequencies do not indicate a significant difference. When these two groups of patients are subdivided into those treated with and without surgery, in row 6, it is of interest to observe the O and A frequencies similar to those of the controls in the small group of patients with low acid and no surgery; no statistical significance was demonstrated in the analysis of the four subgroups; 3 degrees rather than 1 degree of freedom were present. When the 529 patients who had histamine tests performed are studied (row 7), there is seen to be a significant difference, indicating that those having an increase in free acid, as compared with those having no increase in free acid, have a stronger association between the ABO blood groups and peptic ulceration. When the blood-type percentages of the patients with ulcers were examined by decade of age, nothing was found to suggest a relationship of age to the ABO blood groups–peptic ulcer association. This is illustrated in the figure by the absence of significant differences in blood type O frequency when the various decades are compared; similarly, no significance was noted for blood types A, B, and AB. Occupation and social and economic status were studied and appeared equally devoid of significance.

Comment

Of the foremost importance in the interpretation of the findings of this study is the degree of homogeneity or heterogeneity of the controls and patients. In this respect, a relatively stable agricultural population would seem to have advantage in providing source material, as compared with the constantly shifting population found in metropolitan and urban areas, which must necessarily result in relatively more heterogenous groups of controls and patients. Our controls and patients were relatives or friends, with similar genetic, ethnic, and anthropological origins, coming from the same geographical region. A relatively insignificant number of first-generation and second-generation immigrants, from other countries or from elsewhere in the United States, are included. Evidence of the high degree of homogeneity is provided by similar blood-type frequencies observed in the two groups of blood donors and the similar findings noted in an unselected group of patients, with only those with peptic ulcer and neoplastic disease excluded. The use of patients from several hospitals with similar facilities and standards of clinical practice and drawing their patients from the same population group would seem to reduce the chance that the results would be distorted by screening factors related to any one hospital.

The most important single point that emerges from this study is the close agreement of the findings with those previously reported. The level of statistical significance of the association between peptic ulceration and the ABO blood groups is of the same high degree reported by Aird and associates[5] and Clarke and associates[6] in Great Britain and Køster, Sindrup, and Seele[7] in Denmark. Since the Iowa population is derived chiefly from northern European stock, rather minor anthropological differences probably exist between the samples studied. However, in table 6 it will be noted that real differences in blood-type frequencies in controls do exist; for example, of British and Danish controls, 47.1 to 49% and 40.6%, respectively, had blood type O. With each new population group studied, the attractive hypothesis that the findings have an anthropological basis related to population strains with high and low incidence of certain diseases becomes less tenable. However, it may be abandoned only if the results of similar studies conducted in anthropologically dissimilar populations confirm the reported findings. Such studies would also provide strong evidence that there is causal relationship between the ABO blood groups and peptic ulceration rather than just an association.

Our failure to find significant differences between patients with duodenal and gastric ulcers is in sharp disagreement with the findings of Clarke and coworkers[6] and to a lesser extent with those of others. Our findings of a relatively higher frequency of type O than was found by the other workers in gastric ulcer, coupled with a relatively decreased one in duodenal ulcer, are of interest. In table 6 are recorded the data reported by the various investigators (macroscopic diagnosis of duodenal and gastric ulcer) showing the increase or decrease in blood-type percentages of patient groups as compared with the control group. In view of the close agreement noted in duodenal ulcer, it is difficult to find a plausible explanation for the differences observed for gastric ulcer. The accumulation of additional data from these and other sources should ultimately provide the answer to this question.

Of the many avenues that suggest themselves for study, one of the most promising would seem to be the study of the possible relationship of the secretion of blood-type substances. Such data should permit testing of the hypothesis of the possible protective or ulcerogenic effects exercised by these substances upon the mucous membranes of the stomach and duodenum. The possibility exists that as yet undiscovered red blood cell or other associated and similar antigens linked to known type-specific substances may act locally or systemically, being responsible for the findings. Our results suggest that ulcer patients with higher levels of free hydrochloric acid have higher frequencies of blood type O than those with lower acid levels; this could be related to local tissue factors or to more fundamental individual differences. The findings of Struthers[11] and McConnell,[12] as well as our own findings,[13] suggest the existence of similar relationships between the ABO blood groups and disorders other than those of the gastrointestinal tract. This may be a clue suggesting that we are dealing with basic anatomic, biochemical, and physiological differences related to the genetic make up of the individual and, thus, linked to the ABO blood group.

The findings relative to the various clinical characteristics studied are difficult to interpret. Although statistical significance has been shown to exist only for the histamine studies, the total findings related to gastric acidity suggest a relationship here and indicate a need for the collection of more data. In view of a chi-square value approaching a level of significance when comparison of those patients with clinical and surgical diagnoses is made, it is of interest to speculate regarding the possible meaning of these findings. The most interesting and challenging suggestion is that this may be evidence that the ulcer diathesis is more severe in patients with type O than any other type, leading more often to surgical therapy. More probable is the possibility that not all clinical diagnoses were ironclad and thus an unknown number of patients without ulcer were included, lowering the frequency of blood type O in the group with clinical diagnoses. Collection of more data should provide more satisfying answers regarding the possible relationship of these clinical characteristics to the ABO blood groups–peptic ulcer association.

* The discrepancy with table 3 results from the exclusion of patients with ulcers in whom the diagnosis was established by nonsurgical methods

At this time, the explanation for and meaning of the observed association between peptic ulceration and the ABO blood groups remains in the realm of speculation. Although the current evidence does not permit any conclusions to be drawn regarding the possible relationship of these findings to the etiology and pathogenesis of peptic ulceration, a promising new territory has been opened up, exploration of which may ultimately provide some of the long-sought answers to these and other equally pressing questions. As noted in our preliminary report,[14] the findings do suggest that the ABO blood groups may well participate in the process of natural selection.

Summary

In a comparison of the frequencies of the ABO blood types of 1,839 patients with duodenal and/or gastric ulceration with those observed in a representative sample of the population from which the patients came, a highly significant association was noted to exist between the ABO blood groups and peptic ulceration, characterized by an increase in O and reciprocal decreases in the three other blood-type frequencies; the findings are similar for duodenal and gastric ulceration. The level of free hydrochloric acid and whether the diagnosis was anatomic or clinical may possibly have a definite relationship to the association observed, while sex, age, rhesus blood type, and occupation appear to have none.

EXPERIENCE WITH ARTERIAL HOMOGRAFT BANK

REPORT OF ONE HUNDRED CONSECUTIVE ARTERIAL HOMOGRAFTS

William S. Blakemore, M.D., Herndon B. Lehr, M.D.
and
Brooke Roberts, M.D., Philadelphia

• *An arterial homograft bank was established to supply freeze-dried segments of human arteries for use in surgery. Analysis of the results from the first 100 preparations used shows that 36 were used in repairing aneurysms of the abdominal aorta and 24 in relieving arteriosclerotic obstruction in peripheral arteries, with results considered good in 24 and 20 cases respectively. Uniformly good results were obtained in 13 cases of obstruction of the terminal portion of the aorta and 11 cases of coarctation. Mortality was high in ruptured, but low in unruptured, aneurysms of the abdominal aorta. The preparation of materials for the arterial homograft bank can be undertaken by large community hospitals without additional highly trained personnel.*

Many of the technical surgical procedures requiring the use of arterial homografts and the maintenance of arterial homograft banks can easily be provided by large community hospitals without additional highly trained personnel. To encourage others to establish similar banks, the following experiences are presented. An artery bank was first established at the Hospital of the University of Pennsylvania in 1953. A description of methods of preservation that have been used and an analysis of the results of the first 100 consecutive cases in which grafts from this bank were used is presented. This bank has supplied the needs of the Hospital of the University of Pennsylvania and on request has now supplied grafts to 24 other hospitals in the surrounding area. These institutions are in turn asked to help in procuring other grafts.

Methods of Preservation of Grafts

When the bank was established, freeze-drying was selected as the method of preservation and a freeze-drying unit was built.[1] It was of simple construction (fig. 1), and the total cost of the equipment was less than $500. It has required essentially no maintenance. Originally the grafts were all obtained under sterile precautions from fresh cadavers free of infection or malignant disease and were then placed in lactated Ringer's solution, to which antibiotics were added. The grafts were then refrigerated until the freeze-drying process was started. The freeze-drying was accomplished by quick freezing in a mixture of acetone and dry ice, and then the grafts were dried for 36 hours at low pressure (50 to 150 μ Hg). The grafts were then stored in test tubes sealed with rubber stoppers and capped with sealing wax after evacuation of the tube to a pressure of approximately 150 μ.

In the last year this method has been modified in several ways. The grafts are no longer taken under sterile conditions, and any human arteries not showing gross abnormality are considered suitable. Before freeze-drying, the grafts are sterilized with a 1% solution of beta-propiolactone, according to the method

---

From the Harrison Department of Surgical Research and the Department of Surgery of the School of Medicine of the University of Pennsylvania.

developed by Szilagyi and co-workers.[2] Grafts are now kept in sealed glass tubes ridged in order that they may be snapped open easily when needed (fig. 2). These grafts are then reconstituted in 0.9% saline solution, and their branches are tied off with suture ligatures after reconstitution. Prior to the use of sterilization of the grafts, it had become exceedingly difficult to obtain an adequate supply of grafts that fulfilled our criteria. Since the change in method of procurement and sterilization, some of these difficulties have been encountered with less frequency, and, as more interest has developed in the use of arterial homografts, it is becoming easier to obtain material.

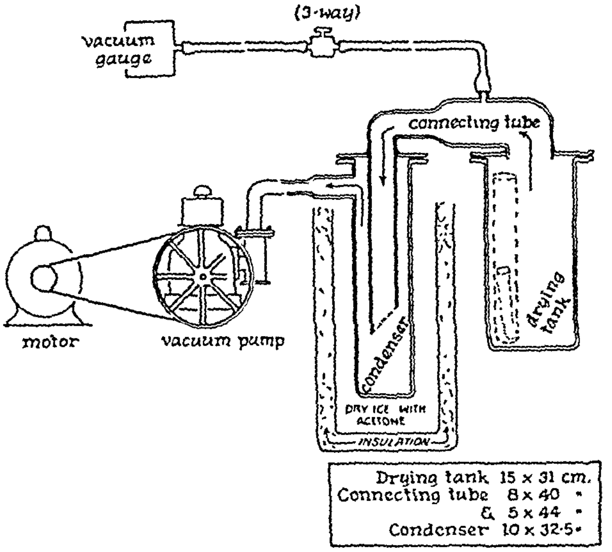

Fig. 1.—Diagram of freeze-drying apparatus.

The sealing of the grafts in glass ampuls has several advantages over the older method: the loss of vacuum that occurred in 10 to 20% of the test tubes when sealed with wax and rubber stoppers is prevented; the danger of contamination is reduced at the time the ampul is opened; and it is possible to sterilize the ampul itself by chemical means so that it can be handled freely by the surgeon. This procedure does, however, require the services of an experienced glass blower, and, if such is not available, rubber stoppers and sealing wax can still be used to obtain a satisfactory seal.

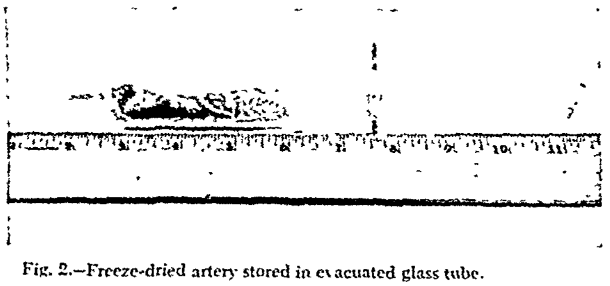

Fig. 2.—Freeze-dried artery stored in evacuated glass tube.

Results with First 100 Grafts

In the table we have tabulated the results obtained from the use of the first 100 consecutive grafts from the bank. It has been possible to obtain follow-up data from every patient in whom they were used. The operative procedures were carried out by 17 different surgeons in 10 different hospitals, but 79 of the 100 grafts were used in the Hospital of the University of Pennsylvania. This table shows a representative cross section of the use of arterial homografts in vascular surgery today. In the analysis of these data we have listed results as good when there was definite improvement after the operation. For example, in patients with obstruction of the terminal portion of the aorta (Leriche's syndrome), if the circulation to both feet was improved after the operation the results have been called good even though pulses may not have been restored to the feet. The results have been listed as fair if the patient has been harmed in some manner even though the over-all result has been an improvement, i. e., after successful removal of an abdominal aneurysm, one patient had a small embolus that blocked one anterior tibial artery and he lost portions of three toes. When the operative procedure resulted in further loss of circulation but not in death, the results have been listed as poor. The patients who died within 30 days after operation have been listed under the column "Died."

Results Obtained from Use of 100 Arterial Homografts at Hospital of the University of Pennsylvania

Disease for Which Graft Used	Total	Good	Fair	Poor	Died
Aorta					
Abdominal aneurysms	36	24	1		11
Thoracic aneurysms	4	2			1
Coarctation	11	11			
Obstruction of the terminal portion of the aorta (Leriche's syndrome)	13	13			
Saddle embolus	1				1
Peripheral arteries					
Arteriosclerotic obstruction	24	20	1	3	
Aneurysm	4	3		1	
Tetralogy of Fallot (Blalock operation)	2	2			
Trauma	3	2		1	
Tumor	1	1			
Thrombosis, superior vena cava	1			1	
	100	79	2	6	13

Examination of the results in abdominal aneurysms shows an operative death rate of 30%. Seven of the 11 deaths, however, occurred in nine patients with ruptured abdominal aneurysms—a group in whom the mortality is inevitably high. In the last 23 consecutive patients having unruptured abdominal aneurysms, there has only been one operative death—a mortality rate of less than 5%. The four patients who died after removal of unruptured aneurysms died of the following causes: (1) pulmonary embolus, (2) uremia, (3) myocardial failure after resuscitation of cardiac arrest while under anesthesia, and (4) rupture of the graft on the 28th postoperative day. This graft failure was the only one encountered in this series of 100 cases and occurred as a longitudinal split at the proximal suture line. There is some question about the reconstitution of this graft, in that it is believed to have been handled before it was completely reconstituted.

Among the patients having coarctation of sufficient length to preclude end-to-end anastomosis, the results of grafting have been excellent. Gross,[3] in a larger series, has also reported good results. We likewise have had satisfactory results in the use of these grafts in patients having the tetralogy of Fallot. Homografts from the bifurcation of the aorta were inserted in 13 patients with obstruction of the terminal portion of the aorta, and all showed some improvement postoperatively.

In the table we have classified the common iliac arteries and any artery distal to them as peripheral arteries. By clinical evaluation, we have found only two late postoperative obstructions in the entire group, and many of the cases have been followed for from one to three years. This is in contrast to the report of Warren.[4] Of our two patients having late obstructions, one was operated on three months later because of thrombosis in another portion of his femoral artery and not in the graft. Another graft was successfully placed in his leg, and the pulse in his foot was again restored. The second patient has reverted clinically to her preoperative state, and additional procedures are contemplated.

Among the peripheral aneurysms that were replaced by grafts, three were in the popliteal artery and one in the femoral. The single poor result occurred in a popliteal artery graft. Of the grafts listed under "Trauma," two were for acute injuries in children, one of the popliteal artery and the other of the brachial artery. The latter graft was unsuccessful, since the arm was gangrenous at the time of operation. The remaining graft was used for an arteriovenous fistula of the subclavian vessels after a gunshot wound. The single patient listed under "Tumors" had a pelvic carcinoma that involved an iliac artery, which was removed and successfully replaced. Only readily available grafts make such unexpected procedures possible.

The replacement of diseased, obstructed, or injured major vessels has gained widespread acceptance, and grafting procedures will undoubtedly be done more frequently in the future. The relative merits of homografts versus prostheses are undetermined, and time alone can give us the answer to many of the controversies. It is our opinion that the majority of surgeons today prefer to use a homograft if a suitable one is readily available. The main objection to the use of homografts has been the difficulty of obtaining and preparing them. We believe that, if banks of the type described here were established in most large communities, homografts could be made available throughout the country and their use greatly increased.

Summary

Experience with the operation of an arterial homograft bank at the Hospital of the University of Pennsylvania has shown that procedures requiring use of arterial homografts and maintenance of arterial homograft banks can be provided by large community hospitals without additional highly trained personnel. A bank of arterial homografts increases the scope of treatment of arterial lesions such as arteriosclerosis, tumor, or trauma.

HOW COMMUNICABLE ARE WARTS?

Roy L. Kile, M.D., Cincinnati

As early as 1896 Jadassohn[1] pointed out that warts may be transmitted from one person to another. The occurrence and regression of these lesions has furnished a fascinating and abundant stock of folklore. Over many years various and sundry remedies have been recommended for the common wart. Nearly every small community has a "character" possessed of special abilities capable of "bewitching" off warts. For some reason the full moon has become important as a factor assisting in the removal of these lesions. Varied remedies have been suggested by lay persons from a list too long to transmit here. These suggestions often come from people who are otherwise apparently quite intelligent. A complete review of the folklore connected with warts would make a fascinating subject for a treatise. Those of us in dermatology hear these stories almost daily.

• *The distribution of warts was studied in an orphanage where 58 children lived during the winter months. Warts were found in 15. The warts in some instances had been present when the child arrived; in other instances they appeared some time after the child's arrival. There were cases of spontaneous disappearance and subsequent recurrence. The distribution of the lesions on different parts of the body did not afford clues as to the method of dissemination, and the time relations of their appearance were not clear. Four out of 18 adults resident in a seminary cottage reported warts; again it was difficult to interpret the data because information as to the time relations and the distribution among other residents was incomplete. Much work on the transmissibility of these lesions must be done before standard hygienic measures can be established. Better knowledge of this virus infection is very desirable because these lesions are so common. They affected at least 20% of the residents in the seminary cottage and more than 25% of the children in the orphanage.*

Read before the Section on Dermatology at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956.

Warts as a Virus Infection

Zwick[2] in 1932 made an interesting review of the subject. He states that the principle of physical disease being cured by suggestion is as dramatically presented with warts as with any disease we know. Bloch[2A] postulated an effect through the vegetative nervous system, causing an unfavorable medium for the virus and hence its death. It has been known, for some years now, that warts are a virus infection. This has more recently been pointed out by Strauss and coworkers[3] in their finding of virus-like particles and inclusion bodies in such skin lesions. They were found in some but not all warts. It is generally conceded by those interested in this field that several strains of virus are the etiological agents for various warts. That they are definitely communicable, however, has not been proved. Clinical reports of possible communicability of warts, therefore, would seem in order. There has been a marked paucity of such reports in the literature. The most pertinent one to the group under consideration here is a study by Grigg and Wilhelm[4] in 1953 on the epidemiology of plantar warts among school children. They examined all the children in the public schools of Dixon, Ill., over a period of one year. Of the students, 4.47% were found to have plantar warts. Incidentally, this study was done entirely with plantar warts and no particular study was made of the other types of warts present. As a control Grigg and Wilhelm checked the students in the neighboring village of Amboy, Ill. There they found 0.72% of the children had plantar warts. They felt the percentages were significant enough to be classed as of epidemic proportions. In a fairly carefully worked out comparison they found the following facts: 1. There was no relation to showers or foot baths. 2. Most of the lesions were multiple. 3. Of the warts, 86.7% were at pressure points. 4. Of the total student group, 10.28% had warts elsewhere on their body. 5. There was no difference in the incidence of plantar warts in other members of the family between children with plantar warts and those without plantar warts. Furthermore, Grigg and Wilhelm were unable to isolate a virus from the specimens they examined. These studies were done for them at the University of Michigan, Ann Arbor, Mich.

More recently an editorial[5] has pointed out that, in an examination of 13,000 school children in England, 9.71 children per 1,000 had warts. It is generally known that warts are much more common in girls than boys.[6] In some series,[7] this difference is four to five times as great. This is an interesting observation, for their presence previous to puberty would make it hard to relate to any endocrine activity. One author[5] theorizes that perhaps girls had more contact with bathroom floors than their brothers. Actually the reason for this sex difference is not known. Two-thirds of the cases occur in the age group 11-15.

Observation of Warts

After reviewing the subject and the major pertinent literature, it was deemed worthwhile to report the following group of cases seen in an orphanage over a period of about 18 months. It became apparent that there was an unusual number of patients with warts being brought to the office from this particular orphanage (it is unfortunate that all the inmates are girls). Two of them had been observed with warts several years previously. Twelve patients with warts of various types were observed over an eight-month period. In several other children there was a definite history of warts having been present previous to the ones seen in this present review. Furthermore, one or two of the patients had warts on entering the orphanage; however, by far the majority of them had been contracted after they came there, and no previous warts had been noted in these individuals (see table). Some 58 children are in this orphanage in the winter, while for the summer about 30 remain. Most of them have one parent or are from broken families to whom they can go during the summer when school is not in session. Therefore, the percentage of 25.8% is rough. On the other hand, there probably are several other children in the orphanage who were not seen and who have warts. I have heard this on rumor from some of the children. Furthermore, some of the children who have had warts that have spontaneously disappeared have never been brought in. While a few plantar warts were noted, the majority of the lesions were on other parts of the body, and, in one instance, the only lesion present was on the lip.

*Data on Fifteen Female Patients with Warts in an Orphanage Group**

Age, Yr.	No. of Warts	Location	Date Noted	Duration When Seen
11	8-10	Hands and left foot	2/13/55	2 mo.
15	2	Hand	7/6/55	8 wk. (had warts as child; cleared and recurred)
10	1	Lip	1/12/55	2 mo.
9	1	Palm of hand	7/6/55	4 mo.
13	4	Hand	3/28/55	2 yr.
10	8-10	Hands and leg	7/6/55	4 mo.
6	10-15	Hands and foot	2/13/52	3 mo.
10	1	Plantar on great toe	2/17/54	1 yr.
13	2	Index finger	6/9/55	3 mo.
13	1	Plantar on heel	12/15/53	4 mo.
15	1	Plantar on ball of foot	9/19/53	6 mo.
11	2	Hands	9/55	2 mo.
9	2	Hands	11/20/54	1 yr.
13	4	Hand	6/22/54	1½ yr. (had warts as child; cleared and recurred)
14	1	Thumb	5/10/55	4 mo. (present before entering orphanage)

*Children in orphanage: 58 in the winter and 20 in the summer. Of the winter group, 25.8% were involved.

I have recently observed, over a period of two weeks, three brothers and a priest from the same seminary with warts on their hands. The priest also had several lesions on his feet. The lesions were quite typical and, with one exception, had appeared since they entered the seminary. The first one to have the lesions was the priest. They lived in a cottage of a group of 18.

Comment

How often have we all seen several members of one family with warts? How significant are these findings? I do not think we can pass by the possible communicability of warts of all types. There are many factors known by all of us that point to their method of spread.

For instance, it is well known that combing the hair, shaving, and similar acts definitely transplant the virus, causing new lesions. However, the spread of lesions from one individual to another is a little more difficult to establish. Undoubtedly it does occur. Whether any precautions should be taken in institutions or schools to isolate individuals with warts is another matter. The consensus seems to be that this is not necessary. It may be, however, that, in institutions such as the seminary or orphanage, individuals with warts should observe some precautions. How strict these should be is difficult to say. Certainly a great deal more work must be done on the transmissibility of these lesions before one can establish such standards. It is not my purpose here to try to set up these requirements but merely to point out the possible communicability of this virus infection of the skin that, while similar to the average virus infection in many respects, also has some interesting differences.

Vaccines of wart tissue are ineffective in the therapy of warts. I tried this therapy in a series of cases, some years ago, using both human wart tissue extracts and wart vaccine prepared from the cow. The results were unsuccessful and never published. Veterinarians employ a wart vaccine in the treatment of lesions on cows that I understand is quite successful. Warts on cows apparently are an entirely different virus, with immune reactions equally as different. This merely helps point out the complexity of the problem as well as the lack of knowledge about the spread of one of the commonest of all diseases. There are probably a number of strains of the virus, some of which may be more communicable than others. This has been pointed out by Blank,[6a] and it may well be the explanation of the variability in apparent communicability of these lesions.

Summary and Conclusions

In two groups of institutional residents the incidence of warts was about the same. Of children in a certain orphanage, 25% developed warts over a one and one-half year period. About 20% of the inmates of a small seminary group did the same over a much shorter period. It is felt that some strains of wart virus are more communicable than others, although this has not been proved. Simple precautions may help to prevent the spread of warts.

BLOOD ASCORBIC ACID LEVEL IN BIOFLAVONOID AND ASCORBIC ACID THERAPY OF COMMON COLD

Warren L. Franz, M.D., G. Winthrop Sands, M.D.
and
Henry L. Heyl, M.D., Hanover, N. H.

• *The incidence and course of common colds were followed in 89 medical students and nurses who volunteered in a study of the efficacy of naringin, a bioflavonoid extracted from grapefruit peel and used in remedies for colds. One group of 22 subjects received 333 mg. of naringin and 65 mg. of ascorbic acid three times daily for three months; a second group received naringin only, another ascorbic acid only, and the fourth a placebo. These substances were administered in capsules as nearly alike as possible. Symptoms of colds were systematically recorded, and the levels of ascorbic acid in the blood were determined periodically. The average level of ascorbic acid in 22 men who were to receive ascorbic acid by mouth was initially 0.96 mg. per 100 cc. of blood; after 12 weeks of taking only ascorbic acid the average for this group was 1.41 mg. per 100 cc. of blood. In all groups and at all stages, the blood ascorbic acid levels for males were significantly lower than those for females. There was no evidence that the naringin affected the ascorbic acid level of the blood, prevented colds, or cured them.*

During the past year treatment with the bioflavonoids has been widely publicized as a means of preventing or modifying the common cold. One of the reasons given for the effect has been that they potentiated ascorbic acid (vitamin C) in alleviating cold symptoms. Since there was no convincing proof available, either in support or in denial, we undertook a pilot study to explore the validity of these statements. Within the limits of this study, the bioflavonoid tested showed effect neither on the incidence or cure of colds nor on the ascorbic acid content of the blood. In the course of the study, interesting data were developed regarding the relationship of blood ascorbic acid levels to the incidence and cure of colds. These are reported in detail.

Method

The study was made on 89 volunteer medical students and student nurses for the three-month period from February to May, 1956. Four groups were established and given capsules (three times daily,

---

From the *Dartmouth* Medical School and the Hitchcock Foundation.

orally) made up as follows: group 1, bland placebo, group 2, naringin (bioflavonoid), 333 mg., and ascorbic acid, 65 mg.; group 3, ascorbic acid, 65 mg.; and group 4, naringin (bioflavonoid), 333 mg. (Naringin is an extract of grapefruit peel.) Every effort was made to disguise the contents of the capsules. All looked and tasted alike. Even the doctors conducting the study did not know the key to the code numbers used. Groups were assigned in rotation. Thus the first volunteer in line received bland placebo, the second naringin (bioflavonoid) and ascorbic acid, and the fifth bland placebo, as the rotation started over again.

Each subject received a regional physical examination and had blood taken for a determination of ascorbic acid level the day he started the study. All the volunteers were started on the regimen within a single week. Thereafter they continued taking their particular capsule for the three months of the study. At the 6-week and 12-week points in the study, determinations of blood ascorbic acid level were made on all 89 participants. The subject was instructed to report cold symptoms (such as coryza, headache, malaise, fever, or sore throat) the day of onset. At this time the physical examination and determination of blood ascorbic acid level were repeated. He was asked to take no specific cold remedies, not even aspirin or nasal sprays, during the course of the infection. He continued taking the same dosage of the capsule assigned to his group. No antibiotics were used. During the infection the same physician made a record (daily when possible) of the cold's progress or regression. On the fifth day the cold was evaluated as cured, improved, unchanged, or worse.

Two variables were accepted as calculated risks to the accuracy of the study: diet and individual reliability. Although the majority of the subjects ate in the same hospital cafeteria, precise control of their diet was felt to be beyond the scope of this essentially pilot study. We recognized, of course, the varying degrees of reliability with which 89 persons would take 3 capsules a day for three months; we believe, however, that close supervision and the medical orientation of the participants kept this factor of error at a minimum.

Tables 1, 2, 3, and 4 give the detailed blood ascorbic acid levels accumulated during this study. They are included in their complete form, partly because they are the basis for the conclusions of this pilot study and partly because comparable records of blood ascorbic acid levels in normal young adults are relatively rare. (Ascorbic acid blood levels were determined according to the technique of Roe and Kuether[1] under the supervision of John P. Davison, Ph.D., assistant professor of the physiological sciences in the Dartmouth Medical School.)

Results

Table 5 summarizes the effectiveness of bioflavonoid with and without ascorbic acid. When used alone, it produced the same results as a placebo. When used with ascorbic acid, the results were comparable to those with ascorbic acid alone. Table 6 indicates that the prolonged administration of bioflavonoid had no effect on the blood ascorbic acid level. Females consistently showed a higher blood ascorbic acid level than males (table 6—statistically significant at the 0.01 level). Most of those receiving ascorbic acid showed an increased blood ascorbic acid level. Those receiving ascorbic acid developed just as many colds as those not receiving it (table 5). In this small series, those receiving ascorbic acid showed more rapid improvement in their colds than those not receiving it (tables 1 to 5 inclusive—statistically significant at the 0.05 level).

Comment

Ascorbic acid deficiencies have been noted not only in classic scurvy but in other infectious and metabolic disorders, such as rheumatoid arthritis, rheumatic fever, tuberculosis, and certain virus infections. The importance of ascorbic acid in maintaining capillary integrity has long been recognized. We will discuss neither the related background nor the literature.

Recently certain naturally occurring substances have been found to have a related function in maintaining the integrity of the intercellular cement substance. The materials as a group have been classified as flavone glycosides and include such substances as hesperidin, rutin, and naringin. We are particularly concerned with those substances derived from citrus fruit peels, grouped together under the title of bioflavonoids. The significant literature on this subject was summarized at a meeting of the New York Academy of Sciences in 1955, which is reported in the annals of that organization.[2] Various articles in this monograph suggest a relationship between ascorbic acid and the bioflavonoids, with particular reference to their effects on capillary fragility. The monograph also reports the clinical use of the bioflavonoids and ascorbic acid in the treatment of disorders related to decreased capillary permeability. These include poliomyelitis, rheumatic fever, and bleeding related to pregnancy. The hypothesis that the bioflavonoids may prevent or modify colds is apparently based on this same property.

With this possibility in view, a number of drug compounds appeared on the market during the winter of 1955-1956 featuring a bioflavonoid content. Most of these compounds also contained such old cold treatment stand-bys as aspirin, caffeine, and ascorbic acid. The limited statements regarding this treatment of colds reported the use of the whole compound, without reference to specific studies based on the effect of the bioflavonoid alone.

We are reporting a pilot study on the effectiveness of one bioflavonoid per se. It is, of course, not definitive. But, in the absence of any comparable evaluation of a material whose commercial distribution is already widespread, we feel that even this limited study may be helpful to the medical profession. The approximately 300 determinations of blood ascorbic acid level were a by-product of the bioflavonoid study. The series is far too small to warrant conclusive interpretations, but the data raise several points of interest that may serve as points of departure in more definitive studies.

Summary

We are reporting a controlled pilot study of the clinical effect of bioflavonoids and ascorbic acid (vitamin C) on the incidence and cure of the common cold, correlated with serial determinations of blood ascorbic acid level on the 89 medical students and student nurses comprising the test group. The administration of a bioflavonoid had effect neither on the incidence or cure of colds nor on the ascorbic acid level of the blood.

This study was supported by grants from the Nepera Chemical Co., Inc., Yonkers, N. Y., and the Harriet M. Spaulding Charitable Trust.

Statistical analyses were done by J. Laurie Snell, assistant professor of mathematics, Dartmouth College.

All drug preparations were provided by the Nepera Chemical Co., Inc.

USEFULNESS OF BIOFLAVONOIDS AND ASCORBIC ACID IN TREATMENT OF COMMON COLD

Harry E. Tebrock, M.D., New York, Joseph J. Arminio, M.D., Ossining, N. Y.
and
John H. Johnston, M.D., West Hartford, Conn.

• *The evaluation of any drug used to treat the common cold must necessarily be based on clinical observations. Bioflavonoids and ascorbic acid, singly and in combination, were evaluated in a study on almost 2,000 persons as to their efficacy, not by symptom alleviation but as to whether it would shorten the course of illness. The overwhelming impression gained from the study presented is the singular lack of effect in altering the course of the common cold by either the bioflavonoid or the ascorbic acid.*

The objective evaluation of a new form of treatment for the common cold has always proved difficult. Since the viruses causing it have thus far completely resisted all attempts at direct annihilation through the use of antibiotics, no bacteriological studies on the disappearance of the causative organism have proved feasible, nor have any other laboratory tests been found of great use in estimating the individual's rate of recovery. Therefore, the evaluation necessarily has been based essentially on clinical observations.

Basically, treatment of the common cold has been limited to the relief of symptoms, the prevention of complications, and the general and specific supportive therapies that enable the body's own defense mechanisms to overcome the disease. Because the illness is essentially self-limited, with serious complications developing in only a small proportion of cases, any therapy that alleviates the patient's symptoms is called a cure until the test of time reduces it to the level of the other drugs that make the patient more comfortable but do not appreciably affect the underlying cause of the disease. To postulate that a given drug has a specific effect upon the disease, therefore, it must be shown that it does more than relieve symptoms. It should shorten the course of the illness. Furthermore, since there are innumerable drugs that make the patient more comfortable and alleviate symptoms, thereby creating subjective evidence that they are affecting the course of the cold, a cold cure should have an effect over and above the best of these relief medications. Lastly, in view of the fact that the evaluation of effect is almost entirely clinical, and therefore subjective from the point of view of either the patient or the observer, the beneficial result of the drug should be demonstrable in a controlled experiment in which personal bias has been entirely eliminated.

In the past decade, much attention has been given to the treatment of colds by the use of drugs that would enhance the body tissue's resistance to invasion. This has been at least in part behind the rationale for the use of such agents as antihistamines.[1] Even more recently, the administration of ascorbic acid (vitamin C) has been advocated,[2] both to raise the general resistance and on the theory that viral invasion is a function of capillary wall permeability that could be reduced by raising the ascorbic acid levels in the blood. On the basis of this theory, ascorbic acid has been added to a number of preparations used for the treatment of acute upper respiratory infections. The most recent approach to the problem has been an extension of this theory. It has been noted that the citrus bioflavonoids enhance the effect of ascorbic acid in maintaining or restoring to normal the integrity of the capillary wall.[3] In particular, they have been reported as directly combating virus infections by preventing the micro-organisms from penetrating the capillary endothelium.[4] It has been logically argued, therefore, that the bioflavonoids can exert a beneficial effect on the body's ability to resist the invasion of respiratory viruses, and several observers have reported cases that appear to substantiate this claim.[4] Because of the widespread interest in this attack on the problem of the common cold, it was felt that a definitive test of these agents would be of considerable value.

Since it is admitted that neither ascorbic acid nor the bioflavonoids have any in vitro effect on respiratory viruses,[7] such a study would have to be entirely clinical. It would be necessary to prove either that an appreciable number of colds were aborted in their early stages or that some or all of the symptoms were cleared up significantly earlier. The effect looked for would be more than a temporary alleviation of symptoms and should therefore be demonstrable even in the presence of other medicaments given merely to that end. To avoid any possibility of observer bias, the trials should be made on a completely blind basis.

Methodology

Since the bioflavonoids were postulated as acting in conjunction with ascorbic acid, it was felt necessary to study the effect of the two substances both singly and in combination. An experimental design was used that would permit the evaluation of each compound independently and also would demonstrate any synergistic effect obtained. The trials were therefore conducted with the following four preparations: (1) 250 mg. of bioflavonoid (lemon bioflavonoid complex 497, Sunkist Growers) plus 50 mg. of ascorbic acid; (2) 250 mg. of bioflavonoid; (3) 50 mg. of ascorbic acid; and (4) placebo.

The subjects were divided into four groups, each of which was given one of these preparations four times a day. In order to demonstrate that any effect ob-

---

Medical Director, Sylvania Electric Products, Inc. (Dr. Tebrock) and Medical Director, Pratt-Whitney and Company, Inc., West Hartford, Conn. (Dr. Johnston).

served was more than that obtainable through standard palliative practice, every patient received a preparation containing 325 mg. of salicylamide, 195 mg. of acetophenetidin, 65 mg. of caffeine, and 50 mg. of thonzylamine hydrochloride. This was done so that a patient not receiving ascorbic acid or bioflavonoid or a combination was actually receiving medication, which, in addition, acted as a control.

Use of these four preparations enables one, by means of a square experimental design, to simultaneously compare the effect of two drugs, both separately and together, and yet to use all the patients in each of the comparisons. In figure 1, each of the boxes represents an approximately equal number of patients receiving the drugs indicated. The effect of ascorbic acid (A in fig. 1) could be evaluated by comparing the upper two boxes and that of bioflavonoid (B in fig. 1) could be evaluated by comparing the two left-hand ones, but this would utilize only half the patients for each evaluation. If, however, the patients in the left-hand side of the square are compared with those in the right-hand half, the effect of ascorbic acid will be demonstrated using all the patients, since the two halves represent the same distribution except for the presence or absence of this factor. The patients indicated in the lower box of each half also receive bioflavonoid, but, since they are about the same proportion of the total, the effect of the latter will cancel out unless a marked synergism is present. The difference produced by bioflavonoid, irrespective of ascorbic acid, can be shown similarly by comparing the upper and lower halves. The amount of synergism or antagonism can be evaluated by determining whether the difference between OO (placebo) and AB is significantly greater or less than the sum of the difference between OO and AO plus OO and OB.

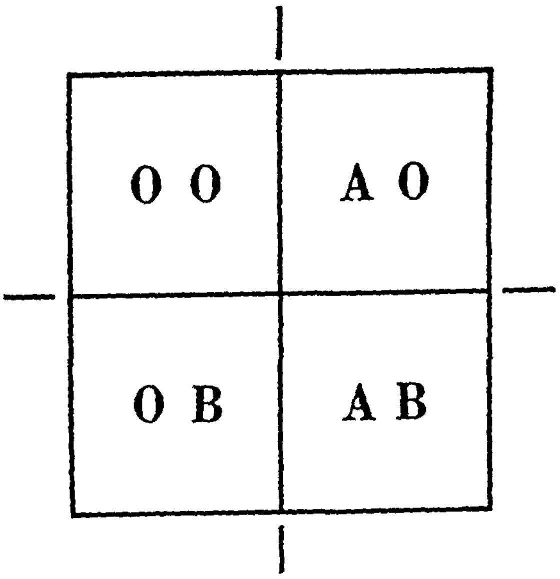

Fig. 1.—Diagram of square experimental design. O = placebo; A = ascorbic acid; and B = bioflavonoid.

The trials were conducted on subjects reporting to several outpatient industrial clinics under the supervision of the physicians conducting the study. A number of college, seminary, and private patients of one of the authors were also included. Medicaments supplied to these physicians were identified only by number, so that neither they nor the patients were aware of what was being given. Furthermore, in order to reduce the possibility of the clinical judgments being influenced by continued association of better results with one of the preparations, each of them was supplied under two numbers, making eight test groups in all to which the patients were assigned in rotation.

Because it was not feasible to reexamine the subjects daily, a single checkup after three days was decided on. It was felt that, if colds were aborted to any appreciable degree by one or both of the drugs, the number of cures after three days should be appreciably higher than in the controls. At the same time, while some alleviation of symptoms was expected in all groups, the proportion should be materially increased in any group receiving an effective therapeutic agent in addition to the palliative medicament. The three-day limit was selected because, with a longer interval, too many cases might resolve spontaneously, while a shorter time would not afford a chance for disappearance of symptoms even under effective therapy. Since the dispensaries were in operation from Monday through Friday, only those cases first seen on Monday, Tuesday, and Friday were included in the study, in order to permit a return at the proper time.

Patients coming to the dispensaries or private offices on those days were first examined. If a diagnosis of an acute upper respiratory infection was made, patients were admitted to the study and assigned to one of the eight test groups in sequence. Their symptoms, physical findings, and other pertinent data were then recorded on a special printed form, which was precoded for machine punching and tabulation. The patient was given sufficient medicament to provide four doses a day for three days and instructed to report back at the end of that time. To simplify compounding and dispensing the medicaments, the ingredients that varied from group to group were put into one capsule, while those given to all groups were put in another. Cough medicine and nasal decongestants were also dispensed if indicated and were recorded on the form. In the case of the industrial patient, when secondary bacterial infection appeared to be developing, he was recommended to his personal physician.

Symptoms to be recorded were limited to eight considered most characteristic of the common cold: running nose, sneezing, hoarseness, cough, malaise, headache, postnasal drip, and sore throat. Only their presence or absence at the initial visit was noted, to avoid the difficulty of grading their severity. The time since the onset of the first symptoms was also recorded, as was the patient's temperature at the initial visit. The notation of physical findings was also limited to those associated with acute upper respiratory infections. Nasal secretions were reported as none, slight or marked, or mucoid or purulent and nasal obstruction as none, partial or complete, or unilateral or bilateral. Pharyngitis was graded as none, mild, moderate, or severe. The diagnoses of pharyngotonsillitis or tracheobronchitis were recorded if present.

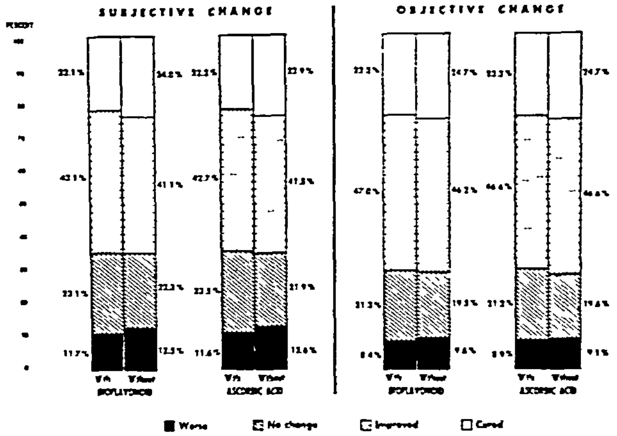

Fig. 2.—Subjective and objective change by drug groups.

At the examination on the third day, the presence or absence of the same symptoms was again recorded, and the physical findings were graded as before. The over-all change in the patient was evaluated, both subjectively and objectively, as worse, no change, improved, or cured. A note was made on whether the patient had taken all his pills and whether he had remained at work and on the number of days lost, if any. All these entries could be recorded on the study form simply by circling the appropriate finding under each heading.

Analysis of Results

Almost 2,000 individuals with acute upper respiratory infections between January and May, 1956, were used in the study. A small number were dropped for failure to report back on the third day, and a few study forms were not completely filled out, but the over 1,900 observations reported under all headings were a more than adequate sample to demonstrate any significant differences that might be produced by the drugs. The coded findings on each case were punched on IBM cards, which were then sorted by test group. These were tabulated for each observation and the distributions percentaged or converted to means. (Where appreciable differences in percentages or means were found, tests for statistical significance were made, using a chi-square test for percentage variations and a t-test for evaluating differences in means. Because of the many observations compared, differences were not considered significant unless the chance probability was 1% or less.)

Table 1 shows the distribution of the eight treatment groups by age and sex. The small differences noted were all accounted for by random sampling variation, and there were no statistically significant differences. The comparability of mean number of colds per year shown in this table indicates that the groups were also random with regard to patients' susceptibility to colds. These eight groups were com-

bined into two groups representing the patients receiving and not receiving bioflavonoids, and also the two different groups that did and did not receive ascorbic acid. The following tabulations are presented for all these combinations. Table 2 gives further evidence of the statistical comparability of the groups. The percentage of patients with pharyngotonsillitis and tracheobronchitis was not significantly different from group to group. Roughly the same proportion of patients required additional medicaments in each group, including antibiotics, nasal decongestants, and cough medicine, in addition to the medicaments under test, and none of these additional medicaments was given in a high enough percentage of cases to have seriously influenced the results of the study. The proportion of patients who did not take all their pills also did not vary significantly between groups. Cross tabulations (not shown) of all these factors against subjective and objective improvement indicated that the elimination of patients who received supplementary medicaments or did not take all their pills would not have appreciably affected the results of the study.

Table 3 shows the effect of bioflavonoid and ascorbic acid on the improvement after three days, judged by both the patient and the clinician. The distributions with and without each of the drugs are almost identical, for both subjective and objective change, with absolutely no statistically significant differences demonstrable. This is graphically illustrated in figure 2. The ameliorating effects of the two drugs on the patients' symptoms are evaluated in table 4. It will be noted that on initial examination the percentage of patients in each group having each symptom was strictly comparable. The number of patients having the symptoms at the end of three days was then tabulated, and the percentage decrease, based on the number originally reported, was calculated. In a few instances patients developed symptoms after the first visit, but these cases were canceled by others in which the symptoms disappeared, and the number in any event was too small to affect the statistical significance of the data. The difference in percentage decrease that might be attributable to drug effect is shown in the right-hand column. It clearly indicates that neither bioflavonoid nor ascorbic acid had more than a random effect on any of the symptoms of the patients.

The effect of the two drugs on nasal secretions is shown in table 5. Again the initial distributions are well within random limits. There is a noticeable drop in the percentage with mucoid secretions after three days, but this change is almost identical in the groups receiving and not receiving both bioflavonoid and ascorbic acid. There is an actual increase in the per-

centage of patients having purulent nasal discharges, probably representing the development of secondary bacterial infection, but once more no significant effect on this phenomenon can be attributed to the drugs being tested. The changes in nasal obstruction in the course of the respiratory diseases are tabulated in table 6. The distribution by degree of obstruction was almost identical before treatment in the test groups. There was a uniform decrease in the amount of obstruction in all groups, with no significant differences attributable to either of the drugs.

In table 7, the amount and severity of the pharyngitis found is tabulated. Again there were no appreciable differences in the distributions before therapy. There was a uniform decrease in the amount of pharyngitis found after three days, with neither of the changes in distribution exhibiting more than random variation.

Although this study was designed for outpatient follow-up, it was felt that the disposition and lost time might shed some light on the function of the drugs. Table 8 indicates that there has been no effect on these factors. The proportion of subjects sent home from work on the first visit could not be attributed to drug effect, but the uniformity noted is another indication of the comparability of the groups with regard to severity of infection. The percentage sent home on a subsequent visit might be an inverse index of the efficacy of the medication, but again there was no appreciable variation. The mean number of days lost, which would be a function of both initial severity and drug effectiveness, also showed no statistically significant differences.

On the theory that the effect of the drugs on capillary permeability might only be beneficial if they were given at the start of the illness, the data on patients treated within 24 hours of the development of symptoms were sorted out and tabulated in table 9 for subjective and objective change after three days. Not only was no difference of effect noticed between the patients who did or did not receive either of the drugs, but the distribution by improvement did not differ significantly from that in the total number of patients, regardless of the number of days since onset (table 3).

Since the study was conducted in the dispensaries or offices under the supervision of three different physicians, it was considered advisable to evaluate some of the findings in each separately, to determine whether any had achieved significantly different results than the others. This analysis for subjective change is shown in table 10. It will be noted that the distributions are noticeably different under the three auspices, with statistical significance at well beyond the 0.1% level between all of them. This is due either to variation among the institutions in the standards for determining the subjective changes or to factors in the composition of the groups or the collateral treatment, such as the inclusion of students and private patients. The locality and the infecting organism may also be a factor. It is interesting, also, that all areas of the United States were included in this study. That it was not due to either bioflavonoid or ascorbic acid is evident from the fact that, despite wide variation in distribution between institutional groups, there were no statistically significant differences due

TABLE 7.—*Decrease in Pharyngitis by Drug Groups*

to the two drugs within any of the groups. The percentage differences noted, particularly in the Pratt-Whitney group, are still within the limits of random variation for a group of this size.

When the study had been running for several months, a preliminary check on the cases already reported indicated no effect from the bioflavonoids. On the off chance that another compound might prove more effective, the medicaments were switched from lemon to orange flavonoid and the study continued. The difference in effect of these two products on subjective and objective change is shown in table 11. While the lack of effect is more evident in the lemon flavonoid group, the differences noted between the patients receiving and not receiving orange flavonoid did not reach statistical significance and can be completely accounted for by chance variation. It will be noted that the results with orange flavonoid were significantly worse than those obtained with the lemon flavonoid controls. This difference is probably due to a change in the severity of respiratory disease in the later months when the orange compound was being evaluated and emphasizes the importance of simultaneous controls as were used in this study.

Comment

The overwhelming impression gained from all these data is the singular lack of effect produced by either the bioflavonoid or the ascorbic acid. If any real clinical response were produced by either of these drugs in even an appreciable minority of the patients treated with them, significant statistical differences should have been evident in at least some of the factors observed. This is particularly so because of the large sample size and the exact comparability of the test groups for all observed factors at the start.

The lack of difference cannot be attributed to the limitation to a single reobservation. In any drug influencing the course of an acute self-limited disease, some changes must be noticeable in at least some of the symptoms after three days or else the effect is so negligible that it can be completely discounted. The procedure used did not evaluate the effectiveness of either of the drugs in preventing secondary bacterial infections and other complications, for which a minimum of a second reexamination after one week would have been necessary, because it had been designed to test the claim that the bioflavonoids, in conjunction with ascorbic acid, aborted or cured the common cold. Neither did it evaluate the use of these vitamins in prophylaxis against the common cold.

The study cannot be invalidated on the basis of too high a percentage of placebo reactors. It is well known that the majority of common colds are alleviated to some extent by the administration of any symptomatic therapy, and the improvement noted in the over 1,900 cases is about what one would expect after three days of such therapy. For the claims for the drugs being tested to be substantiated, there would have to have been present an effect over and above that found for the entire group, and this difference was completely lacking.

It will be noted that no analyses were performed on the individual drug groups to evaluate synergism or antagonism. In the absence of any differences between the combined groups specific for bioflavonoid and for ascorbic acid (see section on methodology), it seemed necessary to look for such effects. It is statistically possible for two drugs to both have a beneficial effect but to be completely antagonistic and cancel each other, in which case the analysis used would yield a false-negative result. An unusual effect of this kind, however, would be immediately apparent by simple inspection of the data at the time the groups were combined, and it was not noted.

Thus far there is no convincing evidence that bioflavonoids or ascorbic acid can alleviate a cold when used alone or in combination with other therapies, and our evidence confirms the conviction that bioflavonoids or ascorbic acid are without specific effect in such conditions. Although some might argue that much higher doses of either bioflavonoids or ascorbic acid are necessary to demonstrate a curative effect, we emphasize that the patients in this study received 200 mg. of ascorbic acid and 1 gm. of bioflavonoid per day, levels generally considered adequate to affect the capillary permeability. Since the usefulness of these compounds in reducing capillary fragility has generally been applied to long-standing conditions, there is no reason to believe that massive doses would achieve the rapid effect necessary in conditions as acute as a cold.

Summary

The effect of 1 gm. of bioflavonoid and/or 200 mg. of ascorbic acid administered daily in aborting or curing the common cold was tested in a controlled double-blind trial on over 1,900 subjects. The medicaments were given, either singly or in combination, in addition to the usual treatment used to alleviate symptoms. No appreciable effects were observed after three days on subjective or objective improvement; on disappearance of running nose, sneezing, cough, hoarseness, malaise, headache, postnasal drip, or sore throat; on decrease in nasal secretions or obstruction or pharyngitis; or in time lost from work. In our opinion neither of these drugs in the dosage given has any significant effect in altering the course of the common cold.

CLINICAL NOTES

A SIMPLE AID IN CALCULATION OF DIETS

Ralph J. Slonim Jr., M.D., Baltimore

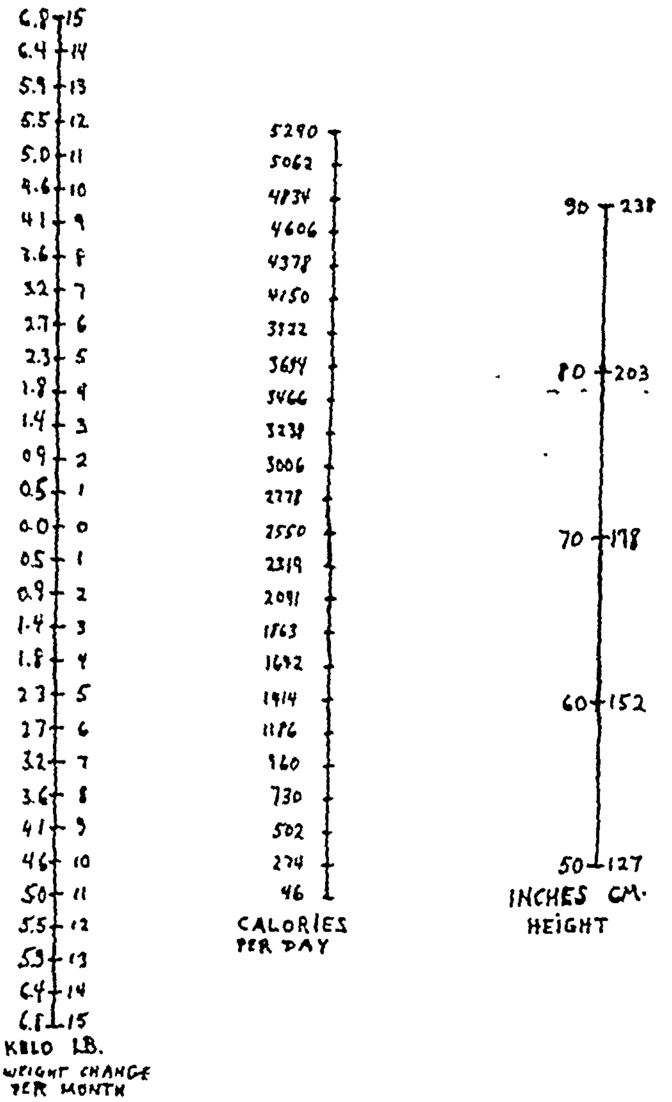
In the construction of diets for alteration of the body weight of adults, certain assumptions have long been employed. Though not entirely accurate, they have the merit of utility and may be stated briefly as follows: 1. For every individual there exists an "ideal" body weight, which may be calculated by a rule of 110 lb. (49.9 kg.) for a person 5 ft. (152.4 cm.) tall, with 5 lb. (2.3 kg.) added for each additional inch. It is customary to allow a variation of 10% in this value, depending on body build. 2. A person who is mainly sedentary requires a daily dietary allowance of 35 calories per kilogram of body weight. If he eats 35 calories per kilogram of his ideal weight, his actual weight, regardless of what it is, will remain constant. If he does heavy labor, however, his caloric requirement may be as high as 40 or 50 calories per kilogram per day. 3. If a person eats more than 35 calories per kilogram of his ideal weight per day, he will gain weight at the rate of 1 gm. of fat plus 1 gm. of water for each 9 calories in excess. If he eats less than the ideal amount, he will lose correspondingly.

These assumptions, admittedly only approximately correct, may be used for calculating weight-changing diets, as in this example. An office worker who is 5ft. 6 in. (167.6 cm.) tall wishes to lose 11 lb. (5.0 kg.) in a month. The required diet is found from the following computations: (1) 11 lb. = 5 kg. = 5,000 gm.; (2) 5,000 gm. ÷ 30 days = 166 gm. per day, equivalent to 83 gm. of fat plus 83 gm. of water per day; (3) 83 gm. of fat is the equivalent of 83 × 9, or 747 calories less

---

From the University Hospital, University of Maryland. Dr. Slonim is now at the Hahnemann Medical College and Hospital of Philadelphia.

than the ideal diet per day to lose 11 lb. in one month; (4) the ideal weight is 110 lb. for the first 5 ft., plus 30 lb. for the additional 6 in. This 140 lb. is approximately 64 kg. At 35 calories per kilogram of body weight, the "ideal" diet is 35 × 64, or 2,240 calories per day; and (5) deducting the required amount (2,240 − 747) gives 1,493, or roughly 1,500 calories per day to produce the desired rate of weight reduction.



Nomogram for calculation of weight-changing diets. Select the patient's height along the right margin and the rate of weight loss or gain desired per month along the left margin. The line connecting these two points crosses the calorie line at the desired daily caloric allowance.

While this type of calculation is simple, it is rather time-consuming. The method can be reduced as follows to a general equation that will cover all cases of moderately sedentary adults. Let H = height in inches, L = pounds per month weight loss (or gain) desired, and C = calories per day. Then, the ideal weight is 5(H − 60) + 110, and the ideal diet in calories per day is

$$35\left[\frac{5(H-60)+110}{2.2}\right].$$

The pounds of fat and of water lost per day are converted to calories lost per day by the term

$$\frac{L \times 9 \times 1{,}000}{2.2 \times 2 \times 30}.$$

The difference between these two terms gives the required number of calories:

$$C = 35\left[\frac{5(H-60)+110}{2.2}\right] - \frac{L \times 9 \times 1{,}000}{2.2 \times 2 \times 30}.$$

This may be further simplified to

$$C = 11.4\,(7H - 266 - 6L).$$

Yet another saving of time and effort may be introduced by constructing a nomogram based on this general equation, by which caloric allowances may be selected at a glance for any desired weight change. Such a nomogram is shown in the figure, based on a standard requirement of 35 calories per kilogram of body weight.

RAPID ESTIMATION OF BLOOD GLUCOSE CONCENTRATION WITH ORDINARY TES-TAPE

Holbrooke S. Seltzer, M.D., Dallas, Texas

An instantly available diagnostic aid and therapeutic guide for the rapid estimation of blood glucose concentration has been conspicuous by its absence. Previous attempts to meet this need by streamlining the usual time-consuming laboratory procedure have included those of Wilkerson and Heftmann [1] and Leech and Woodford,[2] as well as the use of Dextrotest, a simplified blood sugar test outfit. These attempts have not met widespread acceptance because they require special equipment that is cumbersome to operate. An indicator paper known as Tes-Tape is now being increasingly used by patients with diabetes for the detection of urinary glucose. The green-blue spectrum appearing on the yellow Tes-Tape is indicative of the presence of glucose, since the color development depends upon the oxidation of glucose by its specific enzyme, glucose oxidase.[3] The advent of Tes-Tape has enabled development of a rapid and simple means for approximating the blood glucose level. By the method to be described, within three minutes after venipuncture severe hypoglycemia or frank hyperglycemia can be distinguished from an essentially normal blood sugar level. Within another few minutes the blood glucose value can be bracketed with an accuracy varying from 25 mg. per 100 cc. at very low concentrations to 200-250 mg. per 100 cc. at high concentrations of blood sugar.

Materials and Methods

Determinations of glucose in whole blood and plasma were performed in duplicate on 130 specimens of oxalated venous blood by the "true blood sugar" method.[4] The glucose content of each sample of plasma was

---

Clinical Associate Professor of Internal Medicine, the University of Texas Southwestern Medical School, and Chief of the Metabolic Section, Department of Medicine, Veterans Administration Hospital.

simultaneously estimated with Tes-Tape by two different techniques. The first method involved the use of undiluted plasma. One drop of plasma was placed on one end of a strip of Tes-Tape about 1.5 in. in length. Sixty seconds later the darkest color that had developed was compared with the Tes-Tape color card and read on a scale with gradings from "4+" down to "trace" or "faint trace."

The second method involved the use of serial dilutions of plasma. When hyperglycemia was anticipated or when the approximate blood sugar level was unknown, eight small test tubes (e. g., Kahn tubes) were placed in a test-tube rack. Plasma was put into an end tube, and 10 drops of distilled water were added by medicine dropper to each of the other tubes. Ten drops of plasma were mixed with the water in the second tube, and serial dilutions from 0 to 1:128 were obtained. Correspondingly fewer dilutions were made if a normal or low glucose concentration was expected. Eight strips of Tes-Tape about 1.5 in. long were then placed side-by-side on a white paper background. To one end of each strip a single drop of a successive dilution was applied. The "end-point" was that dilution of plasma showing at one minute the last definite greenish tint on the yellow Tes-Tape. The end-point was usually sharp, but comparison with a blank—a strip of Tes-Tape moistened with water—occasionally facilitated decision regarding the last positive dilution. Figure 1 shows the results of the testing by this method of two samples of plasma for which the corresponding blood sugar levels were 93 and 311 mg. per 100 cc.

Results

Blood glucose concentrations of the 130 specimens ranged from 16 to 760 mg. per 100 cc. With few exceptions their corresponding plasma glucose values were slightly higher. The absolute increase of plasma over blood sugar levels varied from -7 to 88 mg. per 100 cc. (mean of 12 mg. per 100 cc.), with the greatest increments accompanying the highest blood glucose concentrations. In all instances blood and plasma values correlated so closely that the Tes-Tape response to plasma glucose reflected the corresponding blood glucose level.

The degree of glycemia could be quickly estimated by use of either of two indexes. A very rapid approximation was provided by the Tes-Tape reaction to undiluted plasma alone. Figure 2 illustrates that, despite considerable overlapping of the color readings for a given blood sugar value, the following interpretations of clinical utility were obtainable: 1. No color or the faintest green tint (faint trace) was evidence of severe hypoglycemia. 2. A pale green of variable intensity (trace to 1+) embraced a wide spectrum extending from very low to moderately elevated blood sugar values. 3. A deep-green color alone (2+) or one merging into blue (3+) signified progressive degrees of hyperglycemia. One factor contributing to the grossness of the interpretation from undiluted plasma was the frequent difficulty in deciding between trace and 1+ or between 2+ and 3+ readings.

Precision in estimating the blood sugar concentration was sharpened considerably by determination of the end-point, as described, for serial dilutions of plasma. Figure 3 demonstrates that the dilution technique permitted much better discrimination between hypoglycemia and normoglycemia. Degrees of hyperglycemia were also distinguished more exactly when the weakest dilution to show a color change on Tes-Tape was read. Not infrequently, however, it was still impossible to differentiate normal fasting blood sugar values from moderately elevated ones. The table is derived from the graphic data shown in figure 3. At each dilution of plasma recorded as the end-point, 90% or more of the corresponding blood glucose values fell within the range indicated. The glucose content of a specimen whose Tes-Tape response ended at or before the 1:2 dilution was alarmingly low, and an end-point at 1:4 still signified clinically important hypoglycemia in most cases. On the whole, the 1:8 dilution end-point indicated either slightly subnormal or normal sugar concentrations. At the 1:16 dilution the corresponding blood sugar value was either in the normal fasting range or moderately high. Positive responses at succeeding dilutions uniformly meant proportionately elevated glucose levels.

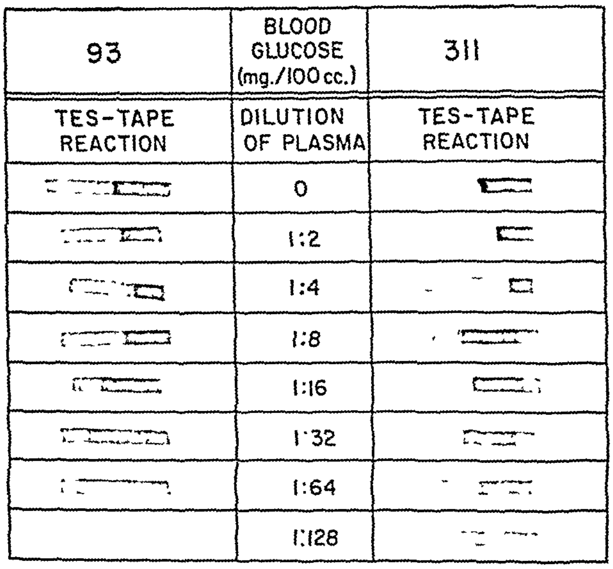

Fig. 1.—Tes-Tape indexes of two samples of plasma for which corresponding blood glucose concentrations are 93 and 311 mg per 100 cc On left, undiluted plasma shows 1+ reaction and last positive dilution is 1:16, on right, respective readings are 2+ to 3+ and 1:32. Two lower strips in each column show slight shadow cast by negative dilutions.

Comment

Depending upon the clinical information desired, the very rapid answer obtained from the Tes-Tape reaction to undiluted plasma may provide sufficient information to render a further plasma-dilution test unnecessary. For example, extreme hypoglycemia and severe hyperglycemia are instantly apparent. However, since the gradation between readings of trace and 1+ or 2+ and 3+ is often indistinct, the much closer approximation made possible by the serial-dilution technique more than compensates for the small additional investment of time.

During the development of the method, certain practical points of procedure became evident, recognition of which should facilitate duplication of the results reported: 1. Only one drop of plasma or its dilution should be placed on the Tes-Tape strip. There should be enough liquid to permit a slowly advancing fluid front during the minute of color development, but a dry area must remain at the time of reading, as shown in figure 1. If the strip is flooded, the excess of glucose-containing solution leads to overreading of the end-point by one or more dilutions. 2. The reading should be made promptly at from 60 to 75 seconds. Not only do some negative dilutions develop a greenish tint after 90 seconds but a blank of Tes-Tape moistened with water sometimes shows a similar color change after a few minutes. Apparently, the indicator in the Tes-Tape system is activated minimally and nonspecifically by water *per se*. 3. There are no false-positive readings, since the enzyme upon which color development depends reacts specifically with glucose.[3] Neither the slight hemolysis sometimes present in plasma nor coexistent high blood levels of fructose interfere with the Tes-Tape response to the glucose concentration.

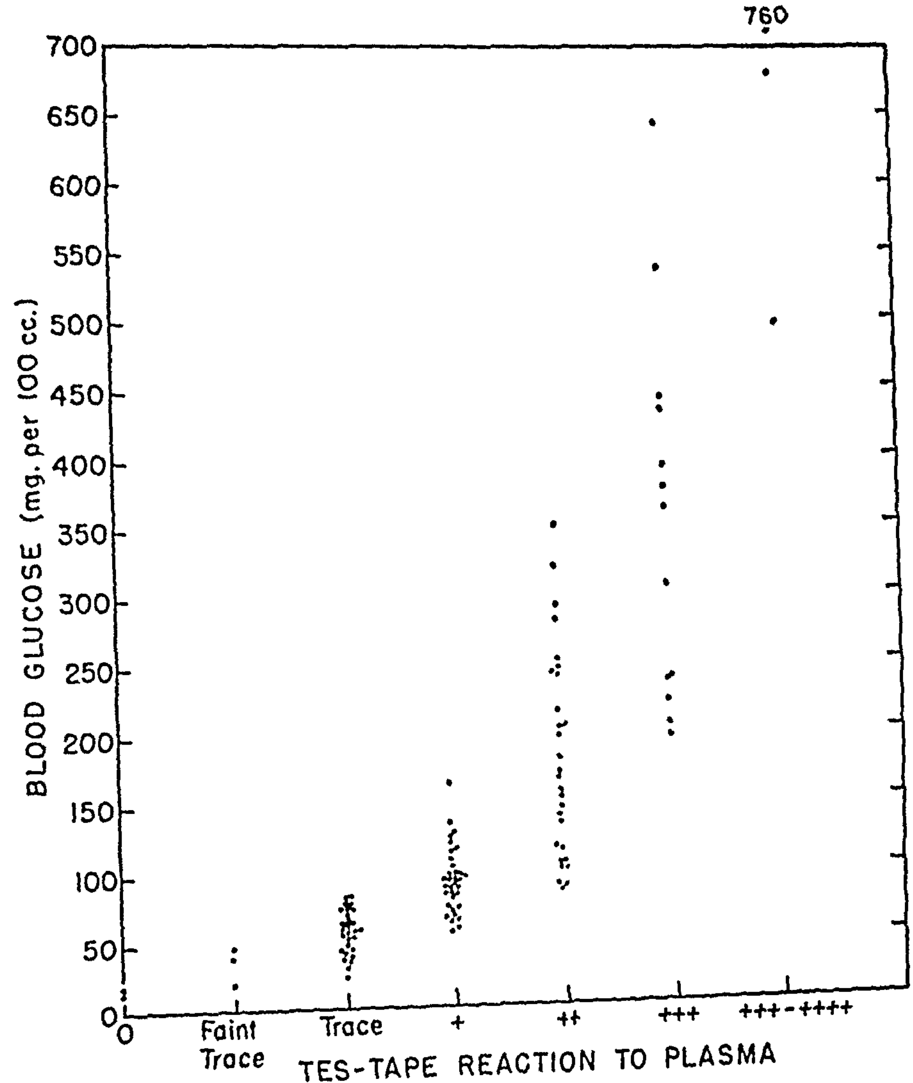

Fig. 2.—Correlation of blood glucose level with Tes-Tape reaction to undiluted plasma. Extreme hypoglycemia and frank hyperglycemia are recognizable, but grossness of reading index prevents good discrimination at intermediate sugar concentrations.

The rapidity with which this simple procedure informs the physician of the approximate blood sugar level of his patient makes it a useful adjunct in several clinical situations. In the emergency room, hypoglycemic coma can be quickly distinguished from other forms of unconsciousness. In the former case, the Tes-Tape will show at best a faint green reaction to the undiluted plasma and be negative beyond the 1:2 dilution, whereas for patients in any other state it will yield a positive response past the 1:4 dilution. On the diabetic ward of the hospital occasions frequently arise when one suspects that a patient may be hypoglycemic. Although the Tes-Tape color response is not keen enough to distinguish mild hypoglycemia from low-normal glucose values, it can easily single out a patient whose symptoms may well be due to hypoglycemia from those with obviously normal or elevated blood sugar levels. The Tes-Tape procedure can also be used conjointly with the method of Duncan and Gill[5] for estimating plasma acetone levels in order to follow the clinical course of a patient in diabetic coma. In the latter test, the diminishing intensity of color change produced by serial dilutions of plasma on the nitroprusside reagent heralds the disappearance of ketosis and a rising carbon dioxide–combining power. Similarly, a falling blood glucose level is signaled by a progressive decrease in the plasma dilution causing the last greenish tint to appear on Tes-Tape.

In addition to the above obvious applications of Tes-Tape, it may also prove useful in the screening of specimens of blood during diabetes-detection programs. The simplicity of the technique overshadows the fact that the Tes-Tape response is slightly less precise than that of the Wilkerson-Heftmann method,[1] the use of which is limited to a few diagnostic centers because of the special equipment and training required. Moreover, once plasma has been separated from red blood cells, the glucose concentration remains virtually unchanged for 48 hours or longer, so that a multitude of samples can be collected and screened en masse. On undiluted plasma, a Tes-Tape response of 3+ would automatically make the donor suspect, and a 2+ reaction would warrant further investigation if serial dilutions remained positive at 1:32 or higher.

Correlation of End-Points of Tes-Tape Response with 90% or More of Corresponding Blood Glucose Concentrations

Dilution of Plasma	Blood Glucose Values, Range of Mg./100 Cc.
0	15-20
1:2	20-40
1:4	35-65
1:8	45-95
1:16	75-165
1:32	145-355
1:64	225-450
1:128	500-760

A final word about the probable future of this test relative to its present status: It is almost certain that we shall ultimately see the development of vastly improved paper indicator systems whereby direct, instantaneous, and highly accurate assessment of the plasma glucose level will be possible. When that happens, ordinary Tes-Tape will become as obsolete as litmus paper. In the meantime, however, the comparatively gross information provided by the method described does not discredit its general applicability today. Here, for the first time, by the use of a "litmus-paper" technique and a material that is available in all pharmacies, valuable information can be quickly obtained regarding the blood sugar concentration of the patient.

Summary and Conclusions

A simple technique, based upon the color response of ordinary Tes-Tape to plasma, enables rapid gross estimation of the blood glucose concentration. Either severe hypoglycemia or frank hyperglycemia can be instantly distinguished from normal blood sugar values by observing the Tes-Tape reaction to undiluted plasma. More precise information is obtained by determining the color response to serial dilutions of plasma. This procedure offers a range of accuracy that is proportional to the actual level of glucose in the blood. At glucose concentrations that are below 50 mg. per 100 cc. one can usually read within 20 to 30 mg. per 100 cc., while at very high levels the reading range widens to 200 to 250 mg. per 100 cc. The simplicity and rapidity of the test and the availability of materials recommend the test for general use whenever prompt information regarding the patient's approximate blood sugar level is desired.

4500 S. Lancaster Rd. (2).

This study was supported in part by a grant from the U. S. Public Health Service.

The Tes-Tape used in this study was supplied by Mr. Walter H. Stein of Eli Lilly & Company, Indianapolis.

MEDICINE AT WORK

THE DOCTORS WHO TALK ABOUT WAR

Around a green baize-covered U-shaped table in Washington, D. C., two dozen doctors were talking about a war they hope never will come. What they heard and said might some day affect not only physicians but all Americans in every walk of life. Here, published for the first time, are elements of that story as it was unfolded last Oct. 25 by representatives of a dozen federal agencies at the meeting of the Committee on Civil Defense, Council on National Defense, of the American Medical Association.

News Item

The U. S. Federal Civil Defense Administration revealed that the government now is completing a prototype of a plastic "basic protective mask" in six shapes and sizes for possible civilian use against chemical warfare. Dr. John M. Whitney, who is director of the health office of the FCDA, told the committee that if and when the government decides there should be mass distribution of the masks, the FCDA simply will rush sets of master molds to manufacturers across the country. The factories then can produce the masks quickly by a plastic injection method. Until now, the FCDA had considered air pollutant defense secondary to nuclear war effects.

Dr. Whitney also announced that medical supplies for three and a half million casualties over a three-week period now are stored in 40 warehouses across the United States and that by 1958 the cache will be big enough for five million victims of any national catastrophe.

News Item

The Atomic Energy Commission's long-awaited new handbook on the effects of nuclear weapons is now in final proof and will be available for distribution in a few months. Robert L. Corsbie of the AEC's division of biology and medicine says the handbook will be in less technical language than a now-outdated edition, and "will be accessible to many more non-scientific people." The publication is expected to answer, for the general public, many persistent questions about radiation and biology associated with H-bomb explosions.

It also may answer criticism that the present administration in Washington has tried to suppress disturbing reports on the dangers of radiation. Said Corsbie: "We believe now that although the law justifiably keeps nuclear devices classified (as secret), information from field tests should be made public. As a result, three-fourths of our 47 weapons test reports will be made available soon." Corsbie, who was on a Navy survey team at Hiroshima in 1945, also revealed that an important re-survey of A-bomb effects in Japan is producing some new and valuable data.

For example, a medical survey team 10 years ago "documented" the case of 100 persons who survived the blast at Hiroshima by seeking shelter in a cave. But last year another team, working with Japanese physicians, carefully reconstructed conditions at the same cave and found that the refugees actually numbered 67, of whom only 2 survived. Says Corsbie: "We feel that if we are wrong on early findings, we should say so. For example, we have thrown out a theory that blast and radiation burns occur only when the victim is in open-line sight of a nuclear blast. That theory was disproven when the explosion of a 15-kiloton device from a 300-foot tower caused burns around the eyes and groin of dogs which were 1,500 feet away in a shelter built with two right-angle turns."

News Item

A nationwide network of "revitalizing" teams is being organized by the U. S. Air Force to speedily restore combat crews into retaliatory shape in case they are hit by an enemy attack. Air Force Col. Joseph Nagle announced that by 1958 eight of these 118-man "casualty management and control" units will be set up near (but not in) Strategic Air Command base areas. He says: "If as a result of these units we can launch one more B-52, they will have paid for themselves." Civilians would not be served by these Air Force units. They would have to "shift for themselves" through their local civil defense organizations and would, in fact, be expected to give medical aid to the military (instead of vice versa) during the early stages of an enemy attack.

Other News

Other news was occurring in that hotel meeting room—news about expanded civil defense training for public health reservists, about a nationwide survey of community water systems, about a few AEC advances against radioactive fallout, and about continuing government research on the effects of nuclear explosions and of biological and chemical warfare contaminants on foods and drugs.

Dr. Harvey Stone of the health resources advisory committee of the Office of Defense Mobilization told the physicians that, to his great surprise, he learned that a single nuclear bomb could wipe out all three U. S. firms that manufacture surgical instruments. Almost the same geographical proximity is true of x-ray equipment companies in this country, he said. It was something to think about.

And there was something else to think about: In case of enemy attack, where does a physician's responsibility lie? Does he rush to duty at his hospital or does he rush into uniform from reserve status? Is

Left, civilian protective mask being developed for possible mass use against chemical warfare. The Federal Civil Defense Administration says that the mask—designed in six variations of shapes and sizes—can be produced in local factories by a plastic injection method. The FCDA would keep the master molds.

Middle, Los Angeles—American Red Cross demonstration of what an "emergency disaster" would be like. Although it was not said, this could have been a cross section of the aftermath of an A-bombing. Realism was added by administration of blood plasma to "victims."

Right, in Flint, Mich., June 11, 1953, "Tornado's Toll," injured residents of Flint lined row on row in the gymnasium of the wrecked school, after the emergency shelter was set up to meet the need of treating injured and homeless when hospitals in the area became packed with casualties. More than 125 persons were killed and many hundreds injured in the violent twister.

it his prime obligation to fulfill key duties in his state civil defense organization, or at the nearby first-aid station—or at the stricken factory where he may have been employed part-time? For many physicians, it can be a multi-responsibility beyond their priority control.

Already, the ODM has a special task force working on the problem. The A. M. A. Committee Chairman, Dr. Harold Leuth, suggested to his colleagues: "The matter of a doctor's dual responsibility is a top cabinet decision in our government." This doctors' dilemma has not yet been resolved; it still is being considered.

Members also are considering the stark contrast of civil defense in this country and in Great Britain. They heard U. S. Army Col. Joseph R. Schaeffer, recently returned from three days in England, say: "The British are very alert to disaster situations. They continually are exercising for atomic war. I saw one man who travelled 200 miles to London at his own expense—just so he could lie in the rubble of a street, as a casualty model wearing realistic-looking wounds. He was observed and worked over by students, passersby, even members of Parliament—all of whom were eager to learn what they could do to help themselves in a disaster. There is nothing like it done in this country. In the extreme apathy in the United States, many of us are geared to believe it won't happen."

Doctors Are the Pathfinders

Nothing like it in this country? A committee member, Dr. Carroll Hungate, questions that. Admittedly, many states have fallen down on civil defense, he said, but others—including California, New York, and Kansas—are pretty well prepared. Dr. Hungate cited a recent exercise in Stanley, Kan., where nonmedical people cared for simulated casualties, and evacuated their entire town to a school house 35 miles away. He said: "In many states doctors have been and are stimulating other people and agencies into civil defense activities. They were in civil defense long before others were." Said another committee member, Dr. Cortez F. Enloe Jr.:

"From the moment the first attack warning comes, something you're doing will be affected by the civil defense measures now planned. This holds true whether you are practicing pediatrics in Paducah or plastic surgery in Manhattan. . . . The ultimate success of the national civil defense program and of the programs of the American Medical Association, of the state, and of county medical societies depends, in the final analysis, not on what authorities think and plan but on what the individual physician does. . . . For the physician, civil defense is a personal matter."

It was an immediate personal matter for hundreds of northern California physicians last Christmas when they put aside holiday plans in order to implement their own long-standing civil defense plans—and thus helped reduce the toll of human life during ravaging floods. It was an immediate personal matter for hundreds more, including 42 public health reservists called to active duty, during last year's New England floods. It was an immediate personal matter for the county medical society members in Fremont, Mich., as they took up the grim task of sorting casualties from a devastating one-two punch delivered by twin tornadoes. Wherever there has been natural disaster, it was the prearranged civil defense blueprint of local medical societies that served the community. And it was during these same disasters that the societies without civil defense training saw higher casualty figures; comparative records across the country prove that.

How to instill civil defense unity without uniformity among this nation's medical men is a major objective of the A. M. A. Committee. One suggestion being considered is the formation of a "national medical board" made up of one doctor from each state medical organization, which would offer ideas for survival. These locally applicable ideas then could be transformed democratically into specific standards and training duties, extending to the county level. As a result, doctors then might be able to do more than just vaguely "help" in their community's civil defense.

Simple geometrics makes it plain that the physician's role in a community disaster is multiplied a thousandfold when a catastrophe strikes the nation. The doctors themselves clearly defined their mission last June when their A. M. A. House of Delegates overwhelmingly voted approval of a national civil defense resolution stating:

"It is therefore the solemn duty of the medical profession, including every individual physician in the country, to exercise his skills, knowledge and best judgment to prevent human suffering and loss of life and to assume responsibility for solution of the complex medical problems arising from instantaneously produced mass casualties."

Pancreatic Insufficiency.—A number of children with cystic fibrosis of the pancreas with complete pancreatic enzyme deficiency as well as a number of healthy children were studied to determine whether the response of their plasma proline levels to the feeding of either gelatin or casein could be used as a simpler and more generally useful diagnostic test. A new simple method for the determination of plasma proline has been found suitable, and its application indicates that it can be used in conjunction with or that it may replace the glycine method The proline method has the advantage that it may be applied after casein or gelatin meals, whereas the glycine method is useful only after gelatin meals. Children with cystic fibrosis of the pancreas with complete pancreatic insufficiency have a fasting proline plasma level much below that of healthy children, whereas the fasting aminoacetic acid levels are approximately the same. The administration of a proteolytic enzyme preparation, papain, with the test meal of gelatin to patients with pancreatic insufficiency results in a significant improvement in protein digestion.—B. S. Gould, Ph D., and H. Shwachman, M.D., Studies in Cystic Fibrosis, A. M. A *Journal of Diseases of Children,* June 1956.

TRAINING OF THE FAMILY DOCTOR

GUEST EDITORIAL

Charles S. Davidson, M.D.

"Everyone wants and should have a family doctor." "This is the age of specialization." "Generalists are our family doctors of the future." "Someday we'll have a doctor for every part of us." "You don't get the personal medical care you used to." "The internist is the general practitioner-of-today." "We must consider the patient as a whole." These statements and many others are from physicians, editors, and lay people. Their variety and very number demonstrate that something is afoot. True—and it is just this: The complexity of modern medicine demands specialists; yet each of us when ill wants a doctor who understands us and will "see us through," who will consider the social, economic, and emotional problems as well as the pain. We might like our family doctor to take care of our glioma, yet we know that a neurosurgeon can do it better. This dichotomy between family doctor and specialist runs throughout medical practice and has given rise to the clichés above as well as to much heated discussion. Part of the heat of the discussion arises from lack of proper definition of a few words.

Let us use the term family doctor for one whom we call first when we are ill, to whom we go for "health examinations"—a physician who knows us as thoroughly as anyone can. Now who is best trained to do this, to be our family physician? Some say the generalist (general practitioner), who is (theoretically) qualified to some extent in all aspects of medicine; some say the internist; and some hope that every physician (including the neurosurgeon above) is capable of such complete medical care.

When we choose a family doctor we want to know not only about his intellectual and moral qualifications but also about his training and experience. Assume that a young man is about to graduate from medical school and wants to be a family doctor. Assume also that he has a fine mind, is morally sound, likes people, and will "make a fine doctor." What advice should he be given for his further training? He does not wish to specialize in surgery, obstetrics, neurology, or psychiatry but wants to be a good doctor. My thesis and my advice to the young man follows. No one can do major surgery, specialized surgery, obstetrics, gynecology, and psychiatry without extensive training in each subject. A person who may do all or most of these and do them well should have, after internship, intensive training and experience for at least four or five years after medical school. He is then qualified to start general practice as defined above. One year of rotating internship today is not enough to permit him to undertake all these things and do them well. In fact, general practice, as I see it, requires more years of intensive training than do many specialties. That this is beginning to be recognized is implied by the formation of general practice residencies by some hospitals. Whether many persons can afford the years of training necessary to become well-trained generalists may be doubted.

If our young man does not want to or is not able to spend this time but still does not want to be a specialist, what is he to do? I would recommend that he spend two or perhaps three years in hard hospital work, much of it in general medicine. During this time he will have worked with specialists such as surgeons, pediatricians, obstetricians, and psychiatrists and will have learned much about the problems with which they are dealing. He will thus be trained to be a family physician—not to do major surgery and probably not obstetrics, unless necessary in his community (and then he will take training), and perhaps will need to refer some or all children's problems to his colleagues in pediatrics. But he is trained to care for everyday problems and illnesses in the family. Perhaps he may wish to specialize in internal medicine, even in one of its subspecialities, and may become qualified for admission to and be certified by the American Board of Internal Medicine, but this is by no means necessary nor usually advisable for his training as a family doctor. Parenthetically, many internists are family physicians today. As the physician grows older and becomes more widely experienced, consultation practice may fall his lot. Just as likely, and in spite of experience and even "boards," he may be happier and be of greater service continuing as a family doctor, calling on others with specialized training when necessary.

Whatever the course of his professional career, our young man will be sufficiently well trained never to undertake that for which he is not qualified. In this "age of specialization," the practice of medicine will continue in its best tradition if each physician does only that which he is capable of doing well, irrespective of postgraduate diplomas and recognition by specialty boards and other approving authorities, for these latter are only gross "paper" standards. A physician's knowledge of his capabilities and his own conscience are far better standards for his conduct as a physician and as to the kind of practice he will undertake than the titles others may give him on the basis of credentials, examinations, and years of residency training. To illustrate: If our young man, after four years of medical school and one of rotating internship, assays to practice medicine, sur-

---

From Thorndike Memorial Laboratory, Boston City Hospital.

gery, and obstetrics, he is fooling not only himself but his patients. So also is the expert neurosurgeon who, unaided, treats diabetes, hypertension, and the occasional obstetric case.

Let us then redefine the kinds of physicians in modern terms and say that the general practitioner will need sufficient training (four or more years after medical school) to permit him to practice medicine, surgery, obstetrics, and other specialties. The family doctor who "knows us best" and "sees us through" as far as his training and capabilities will allow may be such a general practitioner, or, more likely, he will have had far less training—the majority of it in medicine. The specialist has the kind of mind and the training to dig deep into a particular field—be it orthopedic surgery, psychiatry, or cardiology—and probably will have neither the time nor the inclination to be a family doctor, although this does not imply that he is any less a physician in the best sense of the word. We must do well that for which we are trained, but only that of which we are capable.

MEDICINE AND THE ARMED FORCES

Physicians about to perform their military obligation for the first time, their colleagues now in service, and those who have already served would have felt quite encouraged had they witnessed the recent meeting of the Committee on Military Medical Affairs of the American Medical Association. This group, which is a part of the A. M. A.'s Council on National Defense, meets at least twice a year with the expressed hope of securing the optimal interests of the medical and allied professions to serve the nation, compatible with national defense needs. By invitation, this particular committee assists the armed forces in matters of planning for medical care, physician recruitment, reserve programs, military medical supplies, deferment policies, and many other fields where medicine and the military have a joint interest. In addition, this A. M. A. activity carefully investigates complaints, as well as accolades, from physicians who, because of present or past military duties, have written and elaborated on what appear to be either professional injustices or excellent examples of military medicine in action.

The most recent meeting of the Committee was held in Washington, D. C., this past October. Representatives (in most cases the surgeon general, along with members of his staff) of all the armed forces, the Public Health Service, the Selective Service System, and the office of the Secretary of Defense volunteered their time to discuss with the Committee items that would involve a physician and his relation to military medicine. A few of these subjects might serve to illustrate the Committee's activities.

Prime interest was of course centered around the "doctor-draft." Recent newspaper publicity has intimated that the Defense Department is not planning to ask for a continuation of this legislation. The A. M. A. representatives were interested in any future plans for the possible call-up of practicing physicians. Government spokesmen agreed on the diminishing justification of their previous viewpoints concerning this special registration and went on to explain their present concepts for maintaining an adequate number of physicians to care for military personnel. First, they plan to ask amendment of the present regular selective service act to place physicians in the same category as all other specialists occasionally needed to provide optimum security for national defense. Second, initial reports on the Career Incentive Program for Medical Officers (Public Law 497, 84th Congress) seem to indicate an increasing interest in a military medical career, with greater numbers of applications for commissions being submitted and, at the same time, fewer resignations of medical officers. In projecting their needs after June, 1957, based on the continuance of the *status quo* or on improvement in world affairs, the military felt that, by its use of physicians who would have come under the regular draft but who had been deferred to complete their education, in addition to increasing numbers of volunteers, there would be adequate and competent medical care for members of the armed forces.

Military reserve activities were fully explained to the Committee by all the services represented. New programs for reservists, with special emphasis on the potential benefits to the physician becoming a member of a reserve component in his home area, were graphically demonstrated. The Committee requested that all new reserve information be compiled in an easily readable form and published for the information of the profession.

Discussion was also held concerning the dual, or in some cases triple, responsibility of the medical reservist. Specifically, there is the situation of the reserve officer presently in government employ, as in a Veterans Administration hospital. In the event of a state of emergency, which organization has prime call on the man? In a situation where a physician or nurse is a member of a reserve component and holds a key position of supervision in a medical or teaching center, does he or she owe first allegiance to the branch of the armed forces, the affiliated institution, or to community civil defense? The A. M. A. representatives felt this was an urgent problem worthy of further detailed study and secured the assurance of the military medical chiefs not only that such investigation of the government employee–reservist was now in progress but that consideration of the priority of the nongovernment reservist would also be undertaken.

Another of the many matters explored pertained to the new Central Medical Material Supply Program. The responsibility for this particular program is now vested in the Department of the Navy for all three military services. There was an informative exchange of information and ideas, based on past war and peacetime experiences along with projected possibilities, the central theme developed being to provide the most efficient supply service when and where needed, while still maintaining the desired economy of operations.

The cooperative attitude of the military officials in working with the members of the Committee on Military Medical Affairs reflected a sincere desire to work hand-in-hand with organized medicine to achieve that evidently not impossible goal of matching military medicine to its civilian counterpart. Both groups at the meeting, each having its own responsibility—the military to the country's defense and the A. M. A. to the health and welfare of the country as a whole—obviously tried to meet each other halfway. That the meeting brought forth worthwhile discussions on the majority of topics shows this liaison between the practicing physician (regardless of whether he is an A. M. A. member) and the Department of Defense to be an effective link for improving military medicine.

RURAL HEALTH

While illness in a patient may not be clinically different whether he lives in a rural or urban community, the factors concerning the prevention and treatment of his illness vary greatly when the patient is distant from the contributions of a city medical center. Conditions leading to good health in village and country living are admittedly different from those in the more urban parts of the United States. After consideration of the recent reports on air pollution along with crowded living conditions, which are epidemic potentials, it is not impossible to envy the rural citizen. On the other hand, the farmer or rancher usually must be his own public health department, while the city resident has many preventive health measures performed for him through such environmental controls as sewage disposal and through his safe and adequate water supply. Because the rural population has demonstrated its desire to utilize available preventive techniques and, even more so, to understand better how to make the best use of professionally qualified medical care when it is available, and in view of the fact there is insufficient distribution of competent health personnel and facilities in many of these isolated areas, the Council on Rural Health of the American Medical Association has been assisting receptive communities in solving their unique health problems.

The natural problems and influences of an isolated area are not limited to environmental sanitation and animal diseases related to man but also include special adjustments to climate, nutrition, and safety. Whether it be a farm or mining community, to use just two examples, the desire for proper health education seems to be the element making these particular locations warrant special medical study. Until people become aware of a scientific total medical care program, they may be susceptible to any unreliable and unscientific advice that offers relief of aches and pains. They are equally subject to the propaganda of organizations that capitalize on remoteness and keep from them those advances in health and sanitation that would benefit their mode of living.

Rural health is not a misnomer. It is an all-inclusive term describing the path to a more healthful way of life to the citizen in the country. It is basically a lay-sponsored movement to help independent communities help themselves to healthier living by obtaining the active participation of all concerned. First, there are the programs emphasizing the preventive aspects of health, including sanitation of the environment, carried out in cooperation with public health workers. This is the groundwork that stresses the idea of personal protection from future illness and at the same time prepares the population for the acceptance of proper medical care when it is offered. Second, there is the actual providing of medical care by the recruitment of physicians, dentists, nurses, and other ancillary health personnel. These persons, despite their missionary spirit, must feel that they are really wanted and that use will be made of their skills. An example of the success of a rural health program appears in the report of Overholt and the Tennessee Medical Foundation.[1] In this instance, existing cultural patterns of misunderstanding were overcome by providing quality medical care and by having this betterment introduced by, shared with, and then earnestly desired by those who were to benefit from this progress.

While the physician should not claim a privileged position in the rural health movement, he should be available to serve in these ventures and to aid those seeking professional assistance. To solve most, if not all, of the health problems of any rural community in a manner satisfactory to the largest number of its people, the medical profession in addition to its cooperative effort must at the same time insist on self-help, voluntarily contributed.

MEDICINE DISCUSSES WAR

With tension rising and spreading in Eastern Europe and the Middle East, the sadly neglected concept "civil defense" cannot be pushed aside in the United States. Again, the nation's physicians are in the forefront of a continuing civil defense effort, keeping pace with new developments in nuclear, biological, and chemical warfare in order that they may better serve their community and nation in case of attack.

The degree to which civil defense also is a personal matter to physicians is shown repeatedly in each year's hurricanes, floods, fires, and tornadoes—natural disasters wherein the death toll is sharply reduced only when local medical societies act on their civil defense blueprints.

Latest developments to adjust those blueprints are revealed elsewhere in this issue (page 1237) from Washington, D. C., in "The Doctors Who Talk About War." It is a report of last month's meeting of federal representatives with the Civil Defense Committee of the A. M. A. Council on National Defense.

THE PRESIDENT'S PAGE

A MONTHLY MESSAGE

Like many of you, I recently received a four-page brochure urging the compulsory coverage of physicians under the Old-Age and Survivors Insurance provisions of the Social Security Act. This brochure, which gives the subject a quick and easy, "once over lightly" treatment based on questionable facts and figures, is from the committee on social security for doctors of the Physicians Forum.

The source of this material should immediately cast doubt on the accuracy and objectivity of its message. Most physicians will recall that the Physicians Forum was the only medical organization in the country that supported national compulsory health insurance and will not look kindly on any cause that it supports. Nevertheless, this is an issue on which there is room for honest differences of opinion based on facts rather than propaganda. The stepped-up activity of the Physicians Forum should stimulate all members of the profession to learn the facts about compulsory social security coverage for physicians. The issue undoubtedly will be coming up again in the immediate future.

One thing I think we should keep in mind, in order to maintain the proper perspective, is the difference between this problem and an issue like the disability benefits enacted by Congress earlier this year in H. R. 7225. The latter, and similar expansions that surely will be proposed in the future, bring the Social Security Administration closer to regulation of medical care and will have a dangerous effect on the future shape of medical practice.

On the other hand, the inclusion or exclusion of physicians under OASI, while it is vitally important to us as individuals, cannot in itself stimulate further government intrusion in the field of medical care. The issue is primarily one of personal philosophy, economics, and preferred alternatives.

On this issue, the House of Delegates of the American Medical Association has stated its opposition to compulsory coverage of physicians under OASI, although it has made it clear that there is no opposition to voluntary coverage. On the basis of all available evidence, this policy is in accord with the opinion of the majority of American physicians. For example, the House of Delegates, at the 1955 Boston Clinical Meeting, recommended that state societies poll their memberships on this question. The results, as reported at the 1956 Chicago Annual Meeting, showed that 34 state and two territorial societies opposed compulsory coverage. Only three polls could be interpreted as favoring compulsory coverage, and two of those were inconclusive.

More recently, *Medical Economics* magazine reported in its September, 1956, issue on a nationwide survey of more than 10,000 self-employed physicians. This poll eliminated the possibility of voluntary coverage and offered a choice between compulsory coverage and no coverage. The result: 59.8% favored no coverage and 40.2% favored compulsory coverage. In my opinion, the percentage in favor of no coverage will become even greater if every self-employed physician will study this issue and acquaint himself with the black-and-white realities of costs, benefits, and future probabilities.

The majority of self-employed physicians do not retire. About six out of seven doctors now in the 65-75 age group are still in private practice. It is unjust and unreasonable to force physicians to pay taxes into a system from which most of them will get little or no retirement benefits. It is well to remember also that under social security either you collect retirement benefits or your family collects survivors' benefits. It cannot be both. It has to be one or the other. But you as a self-employed physician are not likely ever to see the retirement checks. And the facts show that you can get much better, sounder, and cheaper protection for your family through private insurance companies than you can through social security taxes. This is especially true for younger physicians.

As one last suggestion, I urge you to read and reread the two articles on this subject by Drs. Webster and Coffey that appeared in the Sept. 15 and 22, 1956, issues of The Journal. There you will find an exhaustive collection of facts, figures, and examples that will help you make a decision based on knowledge rather than propaganda. Your decision and that of your professional colleagues—made known in your county and state medical societies—will determine the future policy of your House of Delegates in the American Medical Association.

Dwight H. Murray, M.D., Napa, Calif.

MEDICAL NEWS

CALIFORNIA

Hospital News.—Construction has started on a $500,000 addition to the department of diagnostic radiology at Cedars of Lebanon Hospital, Los Angeles. The expanded facilities will enable the hospital to increase its x-ray service. A conveyor system from the x-ray rooms to the darkrooms for development and to the doctors' rooms for viewing and consultation will expedite the service.

Fatal Case of Plague Reported.—According to the state department of public health, California's first known case of bubonic plague in man since 1917 resulted in the death June 25 of a 43-year-old retired Navy chief petty officer, nine days after his apparent exposure to infected fleas while he was on an outing in Lockwood Valley and Sespe Gorge areas of Ventura County. An investigation by local and state health departments disclosed a number of mummified squirrels and rabbits in the area where the man had walked from his car to do target shooting at a deserted farm. Tests by the state department of public health laboratory confirmed the case as plague resulting from a virulent strain of Pasteurella pestis.

CONNECTICUT

Phi Delta Epsilon Lecture.—The Alpha Rho chapter of the Phi Delta Epsilon fraternity at Yale University School of Medicine, New Haven, will hold its 11th annual lectureship in Yale Medical Center, Nov. 28. The guest speaker, Dr. Gustave J. Dammin, chief pathologist, Peter Bent Brigham Hospital, Boston, will discuss "Current Studies on the Survival of Skin Homografts."

Annual Clinical Congress.—The 31st Connecticut Clinical Congress of the Connecticut State Medical Society and the Yale University School of Medicine, New Haven, will convene at the Hotel Statler, Hartford, Dec. 5-6. Dr. Dwight H. Murray, Napa, Calif., President of the American Medical Association, will deliver the dinner address Thursday, 7 p. m. Registration admitting to all sessions will be $5. Medical students, interns, and residents will be the guests of the congress, if properly certified. In the ballroom Wednesday morning, "Coronary Artery Disease—Physiologic Concepts—Surgical Operation" will be presented by Dr. Claude S. Beck, Cleveland, and "Treatment of Carcinoma of the Cervix" by Dr. Howard C. Taylor Jr., New York. Simultaneously in the Boston room "Modern Treatment of Leukemias and Lymphomas" will be the topic of Dr. William Dameshek, Boston, and "Streptococcal Infections—Their Management and the Prevention of Complications" that of Dr. Benedict F. Massell, Boston. Luncheon in the ballroom will be preceded by a clinicopathological conference conducted by Dr. Joseph E. Flynn, Columbia, Mo., with Dr. Dameshek as discussant, and will be followed by a panel on the management of myocardial infarction, with Drs. Charles K. Friedberg and Irving S. Wright, New York, as collaborators and Dr. Beck as discussant. At 3:15 p. m. the Hezekiah Beardsley Pediatric Society will present "Bilirubin: A Toxic Substance" by Dr. Richard L. Day, Brooklyn, in the ballroom; "The Therapeutic Team in Child Psychiatry" by Dr. I. Peter Glauber, New York, a program arranged by the Connecticut Society for Psychiatry and Neurology will be offered in the Boston-Buffalo rooms; and "Radio-Active Fall Out" will be discussed by Gordon M. Dunning, Washington, D. C., in the New York-Washington rooms. The Thursday morning program will include "An Evaluation of the New Oral Sulfonyl-Urea Drugs in Diabetes Mellitus" by Dr. Max Miller, Cleveland, and "Treatment of Nausea" by Dr. Stewart G. Wolf Jr., Oklahoma City (ballroom), and "Diagnosis of the Acute Abdomen in Children" by Dr. Orvar Swenson, Boston, and "Management of Urinary Tract Infections" by J. Hartwell Harrison, Boston (Boston room). Luncheon in the ballroom will be preceded by a clinicopathological conference conducted by Dr. Harry M. Zimmerman, New York, with Dr. Miller as discussant, and will be followed by a panel on "Gastric Ulcer: Medical Versus Surgical Management," on which Drs. Chester M. Jones and Francis D. Moore, Boston, will serve as participants and Dr. Wolf as discussant. The scientific sessions will end with "Medical Care Plan for Dependents of Military Personnel" (speaker to be announced).

DELAWARE

Research at State Hospital.—A research division that will function as an independent unit at the Delaware State Hospital, Farnhurst, was recently initiated. Dr. Fritz A. Freyhan, clinical director of the hospital, has been appointed director of research. The following projects have been approved: (1) a clinical-sociological study of schizophrenia in Delaware; (2) clinical investigations of the effectiveness of neuroleptic drugs; (3) the effectiveness of intensive psychotherapy in patients with chronic schizophrenic psychoses; and (4) cerebral blood flow and metabolism in psychiatric disorders (for which the National Institute of Mental Health has awarded a grant of $23,500 for a five-year period). The other projects will be financed from a special research fund appropriated by the state legislature.

FLORIDA

Geriatric Seminar at Sarasota.—The Sarasota and Manatee county medical societies and the Manasota Medical Foundation will present a Geriatric Seminar, Dec. 3-7, at the Orange Blossom Hotel, Sarasota. The seminar is approved for credit for postgraduate study by the American Board of General Practice. Drs. Hal M. Davison, Harold P. McDonald, Alva H. Letton, and T. Sterling Claiborne, Atlanta, Ga., will discuss a wide range of topics, including allergy in the aged, gallbladder disease, cardiac irregularities, coronary arteriosclerosis and thrombosis, cancer of the thyroid, teaching of psychosomatics, gastrointestinal and genitourinary disturbances, prostatic obstruction, and nutrition. There is no registration fee.

ILLINOIS

Pathologists Meet in Springfield.—The Illinois Society of Pathologists will hold its fall meeting Dec. 1 at St. Johns Hospital in Springfield, under the presidency of Dr. Dennis B. Dorsey, Danville. A slide seminar, 9 a. m., will have as moderator Dr. Grant C. Johnson, Springfield, and as panel members Drs. Harold D. Palmer, Springfield, and Paul E. Steiner and Mark C. Wheelock, Chicago. A luncheon and business meeting are scheduled for 1 p. m.

Clinics for Crippled Children.—The University of Illinois division of services for crippled children has scheduled the following clinics to which any private physician may refer children for consultative services:

Nov. 27, Effingham (rheumatic fever), St. Anthony's Emergency Hospital, Peoria, Children's Hospital.
Nov. 28, Aurora, Copley Memorial Hospital, Springfield (cerebral palsy), Memorial Hospital.
Nov. 29, Decatur, Decatur and Macon County Hospital.
Nov. 30, Chicago Heights (cardiac), St James Hospital.

Chicago

Lecture on Cardiac Lesions.—The South Chicago branch of the Chicago Medical Society in cooperation with the Chicago Heart Association will present "Recognition of Common Cardiac Lesions" by Dr. Peter J. Talso, associate professor of medicine and assistant chairman, department of medicine, Stritch School of Medicine of Loyola University, Nov. 27 at 9 p. m. Audience participation and a social hour will follow the lecture, which will be delivered at the Illinois Central Hospital (cafeteria), 5800 Stony Island Ave. (phone: MIdway 3-9200).

Kaplan Lecture in Neuropsychiatry.—The Phi Delta Epsilon Foundation of Chicago announces that the 1956 Dr. Leo A. Kaplan Second Annual Lecture in Neuropsychiatry, "Influence of Psychosomatic Concepts on General Medicine," will be delivered by Dr. Theodore Lidz, professor of psychiatry, Yale University

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

School of Medicine, and psychiatrist-in-chief, Yale Psychiatric Institute, New Haven, Conn. Dr. Lidz, who is president-elect of the American Psychosomatic Society, will speak at the Drake Hotel, Nov. 29, 8 p. m. All physicians and interested persons are invited.

MASSACHUSETTS

Personal.—Dr. John M. Kinney, senior assistant resident surgeon, Peter Bent Brigham Hospital, Boston, has received the second annual Mead Johnson Award for Graduate Training in Surgery. The award, made through the scholarships committee of the American College of Surgeons, provides $3,000 annually for a three-year period. Dr. Kinney's studies are concerned with methods that could be utilized postoperatively either to increase the level of conversion of carbohydrates into energy or to provide increased amounts of carbohydrates for the metabolic process.

MICHIGAN

Dr. Karsner to Give Weller Lecture.—The Michigan Pathological Society has announced the establishment of the Carl V. Weller Lectureship in recognition of the contributions made by Dr. Weller in the fields of pathology and clinical pathology. The first lecture will be given in Ann Arbor, Dec. 8, by Dr. Howard T. Karsner, Washington, D. C., medical advisor to the Navy.

Personal.—Donald G. Marquis, Ph.D., chairman, department of psychology, University of Michigan, Ann Arbor, has been appointed a member of the National Advisory Mental Health Council, the surgeon general, U. S. Public Health Service, has announced. This council advises and makes recommendations to the surgeon general regarding activities of the National Institute of Mental Health.

MINNESOTA

Personal.—Dr. Edward A. Meyerding, St. Paul, executive secretary, Minnesota Tuberculosis and Health Association, has been awarded the William G. Anderson service award by the American Association for Health, Physical Education, and Recreation for his work in developing better health programs and environment for Minnesota school children. Dr. Meyerding's public health career began in 1909 with his appointment as director of hygiene of the St. Paul public schools.

NEW JERSEY

Society News.—The New Jersey Orthopedic Society recently elected Dr. Bernard M. Halbstein, Long Branch, president; Dr. Harold T. Hansen, South Orange, president-elect; Dr. Otto Lehmann, Long Branch, secretary, and Dr. John M. Naame, Atlantic City, treasurer.

NEW YORK

Meeting on Industrial Medicine.—The New York State Society of Industrial Medicine, will hold its annual meeting at the Hotel Roosevelt, New York City, Dec. 6, 4:30 p. m. "Radioactivity and Its Applications, with Particular Reference to Industry" will be discussed by Samuel A. Lough, Ph.D., deputy director, health and safety laboratory, Atomic Energy Commission; "Radioactive Fall-Out" by John H. Harley, Ph.D., chief, analytical branch, health and safety laboratory, AEC; and "Biologic Effects of Radiation" by Henry A. Blair, Ph.D., director, atomic energy project, University of Rochester School of Medicine and Dentistry. Cocktails and dinner are scheduled for 7 p. m. Requests for reservations should be sent to Dr. Harry E. Tebrock, New York State Society of Industrial Medicine, 1740 Broadway, 14th Floor, New York 19.

New York City

Conference on Mental Hygiene.—All directors of clinical laboratories and senior pathologists of the New York State Department of Mental Hygiene have been invited to participate in a one-day conference at the New York State Psychiatric Institute, Nov. 30, 9 a. m.-5 p. m. The program will feature a neuropathological seminar on diagnostic problems and unusual neuropathological conditions; a symposium on liver pathology in relation to recently used pharmacological therapy in mental disorders; and a series of scientific papers on clinical-pathological reports.

NORTH CAROLINA

Annual Gaston Symposium.—Dr. Nicholson J. Eastman, professor of obstetrics and director of the department of obstetrics at Johns Hopkins University School of Medicine and obstetrician-in-chief at Johns Hopkins Hospital, Baltimore, will be the guest speaker for the fifth annual Gaston Memorial Hospital Symposium in Gastonia, Nov. 28. Dr. Eastman will speak at 4 p. m. on "Apnea Neonatorum." His topic for the evening meeting will be "Maternity Care in Global Perspective." All sessions will be held at the Masonic Temple.

OHIO

Grant for Leukemia Study.—The John A. Hartford Foundation has made a grant of $162,075 to the Toledo Hospital for a three-year study of the causes and treatment of leukemia. The study will be conducted under the direction of Dr. Bernhard Steinberg, director, Toledo Hospital Institute of Medical Research, in conjunction with a group consisting in part of a clinical hematologist, Dr. Muvaffak A. Atamer, and a biochemist, Leon Libenson, Ph.D. The investigation is a transference of the basic research done at the institute for the past 11 years.

Seminar on Obstetrics and Gynecology.—The Southwestern Ohio Society of General Physicians in collaboration with the Cincinnati Obstetrical and Gynecological Society and the University of Cincinnati College of Medicine, offers a seminar on obstetric and gynecologic problems Nov. 26, in the medical school auditorium (emergency call answering service, AVon 1-2568). Among the topics to be discussed are bleeding in early and late pregnancy and after delivery; management of prolapse of cord and of convulsions; amniotic fluid embolism; aspiration during anesthesia; abnormal vaginal bleeding before menopause and postmenopausal bleeding; and pelvic pain. A question-and-answer period is scheduled for 3:15 p. m.

OREGON

Society News.—Dr. Herman A. Dickel, Portland, president-elect of the Multnomah County Medical Society, was recently elected charter president of the Portland Psychiatrists in Private Practice, an organization designed to study the situations, information, and problems incidental to the private practice of psychiatry. Other charter officers are Drs. Siegfried R. Berthelsdorf, Portland, secretary-treasurer, and DeWitt C. Burkes, Portland, executive committee member.

Course on Allergy.—A postgraduate course on allergy will be given Dec. 3-5 in the auditorium of the University of Oregon Medical School, Portland, under the sponsorship of the division of allergy of the medical school, the Allergy Society of Oregon, and the American Foundation for Allergic Diseases. Guest lecturers will be Dr. Ethan A. Brown, assistant professor of pediatrics, Tufts College Medical School, Boston, president of the American College of Allergists, and editor of the *Annals of Allergy*, and Dr. Orval R. Withers, associate clinical professor of medicine. The program will include round-table discussions and clinical demonstrations. Enrollment is unlimited, with a tuition fee of $25 for the course. Eighteen hours of Category I credit will be allowed by the American Academy of General Practice.

PENNSYLVANIA

Philadelphia

Ex Residents' Dinner.—The annual dinner of the Philadelphia General Hospital Ex Residents' Association will be held at the Penn-Sherwood Hotel, Dec. 4, 7 p. m.

Dr. Parkinson Accepts Reappointment.—On the request of President Robert L. Johnson, LL.D., and the executive committee of Temple University, Dr. William N. Parkinson has agreed to forego retirement plans as dean of the medical school and vice-president of the medical center and to accept reappointment in this dual capacity for an additional three-year period. The request on the part of university officials was prompted in part by the current extensive 12 million dollar expansion program at the medical center. Dr. Parkinson, who came to the medical school as associate dean in 1926, has been dean since 1929.

TENNESSEE

Personal.—John P. Quigley, Ph.D., Memphis, has been appointed by the surgeon general to serve as a member of the selection committee for the senior research fellowships granted by the National Institutes of Health.

Convulsive Seizure Clinic.—The University of Tennessee College of Medicine, Memphis, has opened a Children's Convulsive Seizure Clinic in the Pediatric Clinic of the John Gaston Hospital under the direction of Dr. James G. Hughes, professor of pediatrics. The new clinic, limited to patients of the hospital's outpatient department, will provide comprehensive diagnosis and treatment for children with convulsive seizures and undertake intensive study of the affected children.

TEXAS

New Regulations on Radiation Exposure.—The Texas State Board of Health has adopted new regulations on radiation exposure, which became effective Sept. 1. The state health commissioner, Dr. Henry A. Holle, Austin, states that these regulations are consistent with the National Committee on Radiation Protection report, which was prepared on request from representatives of the American College of Radiology, the American Medical Association, and the U. S. Public Health Service. The following points summarize the principal aspects of these regulations: 1. It requires registration of all radioactive materials and radiation-producing machines, such as x-ray equipment, within 30 days of commencement of use. 2. It establishes certain definitions, terminology, and official radiation symbols. 3. It establishes standards for air, water, and other environment. 4. It requires designation of a responsible person to be in charge of radiological safety programs. 5. It requires personnel monitoring and maintenance of records and reports under certain specified conditions. 6. It requires labeling of hazardous material and identification of areas where radioactive material is stored. 7. It requires permission prior to dumping or burying of radioactive wastes. 8. It requires reporting of accidental release of radioactive material that leaves premises of the user. 9. It requires reporting of accidental exposures received by a person when dose exceeds five times the permissible amount. 10. It allows certain specified exemptions. These regulations do not apply to the kind or amount of radiation that may be applied to a person for diagnostic or therapeutic purposes by or under the direction of a physician or dentist.

WASHINGTON

State Medical Election.—Officers of the Washington State Medical Association include Dr. James H. Berge, Seattle, president; Dr. Milo T. Harris, Spokane, president-elect; Dr. Walter C. Moren, Bellingham, vice-president; Dr. Frederick A. Tucker, Seattle, secretary-treasurer; and Mr. Ralph W. Neill, Seattle, executive secretary.

WEST VIRGINIA

Society News.—Dr. Clark K. Sleeth, Morgantown, was recently installed as president of the West Virginia Heart Association; Dr. Lynwood D. Zinn, Clarksburg, was named vice-president; Dr. James H. Walker, Charleston, secretary; and Mr. R. E. Plott, Charleston, treasurer (reelected).

Panhandle Medical Jubilee.—The Eastern Panhandle Medical Society will celebrate its golden anniversary at a banquet at the Shenandoah Hotel in Martinsburg, Dec. 1. The speaker, Dr. Louis A. M. Krause, is professor of clinical medicine at the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, and a teacher of the history of medicine. A social hour will precede the banquet, and at the conclusion of the program there will be a reception and dancing.

Institute on Medical Practice.—An all-day postgraduate institute, regional meeting, sponsored by the West Virginia chapter of the American Academy of General Practice and the Eastern Panhandle Medical Society, will be held at the Shenandoah Hotel in Martinsburg, Dec. 2. The lecturers have been voted best in their respective categories, or as best all-around lecturers, by the seniors in the medical schools represented on the program:

Diagnosis and Treatment of Sciatica, Dr. Bernard J. Alpers, professor of neurology, Jefferson Medical College of Philadelphia.

Poisoning in Children, Dr. John E. Bradley, professor of pediatrics, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore.

Subject to be supplied, Dr. Robert J. O. Coffey, professor of surgery, Georgetown University School of Medicine, Washington, D. C.

Subject to be supplied, Dr. Eleanor Delfs, associate professor of obstetrics, Johns Hopkins University School of Medicine, Baltimore.

Obesity, Dr. William Parson, professor of internal medicine, University of Virginia School of Medicine, Charlottesville, Va.

A Rational and Aggressive Plan for the Management of Acute Upper Gastrointestinal Hemorrhage, Dr. Charles M. Thompson, professor of medicine and head, department of gastroenterology, Hahnemann Medical College and Hospital of Philadelphia.

Modern Concepts of Toxemias of Pregnancy, Dr. Washington C. Winn, professor of clinical obstetrics and associate professor of clinical gynecology, Medical College of Virginia, Richmond, Va.

WISCONSIN

Personal.—Edmund Fitzgerald, Ph.B., LL.D., president, Northwestern Mutual Life Insurance Company, Milwaukee, has been appointed to serve on the National Advisory Health Council, the surgeon general, U. S. Public Health Service, announced Oct. 19. The council is composed of 12 nonfederal leaders in medical science and public affairs, with ex officio members from the Department of Defense and the Veterans' Administration. On the council's recommendation, the surgeon general awards grants to scientists in hospitals, universities, and other nonfederal institutions conducting research.

Symposium on Immunology.—The Milwaukee Academy of Medicine will present an all-day symposium on immunology at Marquette University, Brooks Memorial Union, Dec. 1. The faculty will include Drs. Frank J. Dixon Jr., University of Pittsburgh School of Medicine; Tzvee N. Harris, University of Pennsylvania School of Medicine, Philadelphia; William B. Sherman, Columbia University College of Physicians and Surgeons, New York; Carl V. Moore, Washington University School of Medicine, St. Louis, and Theodore L. Squier, Marquette University School of Medicine, Milwaukee. All physicians are welcome. There will be no registration fee. Luncheon will be served at the union. Reservations may be secured through the Milwaukee Academy of Medicine, 561 N. 15th St., Milwaukee 3.

WYOMING

State Medical Election.—Newly elected officers of the Wyoming State Medical Society include Drs. Joseph S. Hellewell, Evanston, president; Harlan B. Anderson, Casper, president-elect; Luther H. Wilmoth, Lander, vice-president; Benjamin Gitlitz, Thermopolis, secretary; and Carleton D. Anton, Sheridan, treasurer.

GENERAL

A. M. A. Seattle Clinical Meeting, Nov. 27-30.—Physicians who attend the Clinical Meeting in Seattle may decide which and how many of 21 panel discussions, 46 lectures and talks, 18 television clinics, 24 motion pictures, and 97 scientific exhibits they desire to attend. Much effort has been made to bring practical solutions to everyday problems with a panel discussion on office gynecology, lectures on office treatment of varicose veins and office treatment of mild depressions, and a motion picture on office management of arthritis.

The Scientific Program starts Tuesday morning and continues until Friday noon at the Civic Auditorium. On Tuesday evening, a special showing of a motion picture "The Medical Witness" will be presented at the Olympic Hotel, with introductory remarks by C. Joseph Stetler, Director, Law Department, American Medical Association; David F. Maxwell, President, American Bar Association; and David B. Allman, President-Elect, American Medical Association.

Capps Prize for Medical Research.—The Joseph A. Capps Prize for Medical Research ($300), founded by Dr. and Mrs. Edwin R. LeCount, is being offered by the Institute of Medicine of Chicago for the most meritorious investigation in medicine or in the specialties of medicine. The investigation may be also in the fundamental sciences, provided the work has a definite bearing on a medical problem. Competition for 1956 is open to graduates of Chicago medical schools who completed their internship or one year of laboratory work within five years before Jan. 1, 1956, excluding their terms of service in the armed forces. Manuscripts must be submitted to the Secretary of the Institute of Medicine of Chicago, 86 E. Randolph St., Chicago 1, not later than Dec. 31. The manuscript of the prize paper, as submitted, will become the property of the Institute of Medicine of Chicago.

Committee on Disaster Studies.—The committee on Disaster studies, of the division of anthropology and psychology, National Academy of Sciences-National Research Council (2101 Constitution Ave., Washington, D. C.), was established as the result of a request made of the academy-research council by the surgeons general of the Army, the Navy, and the Air Force, that it "conduct a survey and study in the fields of scientific research and development applicable to problems which might result from disasters caused by enemy action." The committee maintains a clearinghouse on disaster research, publishes a roster of scientific personnel in the field of disaster research, and issues a newsletter. It makes grants to encourage research in disaster studies, advises with responsible officials on problems of human behavior in disaster, and reports on the results of disaster research. Both new reports and previously unpublished work are selected for publication. Members of the committee serve without compensation beyond their actual expenses. Activities are presently supported by a grant from the Ford Foundation and by a special grant from the National Institute of Mental Health of the Department of Health, Education, and Welfare. Grants for the work of the committee are received and administered by the National Academy of Sciences. Established by Act of Congress in 1863, the academy is a private nonprofit organization of scientists dedicated to the furtherance of science and to its use for the general welfare. Pursuant to a request made by President Wilson in 1916, the academy organized the National Research Council.

FOREIGN

Swedish-American Exchange Fellowship.—The American Cancer Society in cooperation with the Anti-Cancer Society of Sweden has completed plans for a Swedish-American Exchange Fellowship program that will encourage an interchange of American and Swedish cancer research scientists.

Hadassah Establishes Health Center.—Hadassah, the Women's Zionist Organization of America, has announced as an eighth anniversary gift to the state of Israel the establishment of a Community Health Station, equipped to provide preventive, diagnostic, and curative physical and mental health services, in the all-Arab village of Abu Ghosh on the Jerusalem-Tel Aviv Highway. The new program for Abu Ghosh will include the dissemination of the latest information about health and sanitation, the breaking down of cultural or environmental taboos interfering with sound physical or emotional health, vaccination and immunization, treatment of existing physical ailments including dental and eye care, and the treatment of emotional tensions within the family group.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

Alabama: *Examination.* Montgomery, June 18-20. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

Arkansas:* *Examination and Reciprocity.* Little Rock, Nov. 8-9. Sec., Dr. Joe Verser, Harrisburg.

California: *Oral Examination for Reciprocity Applicants.* Los Angeles, Nov. 17. Sec., Dr. Louis E. Jones, 1020 N Street, Sacramento.

Colorado:* *Examination.* Denver, Dec. 4-5. Final date for filing application was Nov. 2. Sec., Dr. Samuel H. Brown, 831 Republic Bldg., Denver 2.

Connecticut:* *Examination.* Hartford, Nov. 13-15. Sec., Dr. Creighton Barker, 160 St. Roman St., New Haven.

Delaware: *Examination.* Dover, Jan. 8-10. *Reciprocity.* Dover, Jan. 17. Sec., Dr. Joseph S. McDaniel, 225 So. State St., Dover.

District of Columbia:* *Examination.* Washington, Nov. 13-14. Deputy Director, Mr. Paul Foley, 1740 Massachusetts Ave., N.W., Washington 6.

Florida:* *Examination.* Miami Beach, Nov. 25-27. Sec., Dr. Homer L. Pearson, 901 N.W. 17th St., Miami 36.

Idaho: *Examination and Reciprocity.* Boise, Jan. 7-9. Exec. Sec., Mr. Armand L. Bird, 364 Sonna Bldg., Boise.

Iowa:* *Examination.* Des Moines, Dec. 3-5. Ex. Sec., Mr. Ronald V. Saf, State Office Bldg., Des Moines.

Kansas: *Examination and Endorsement.* Topeka, Dec. 12-13. Sec., Dr. Lyle F. Schmaus, 872 New Brotherhood Bldg., Kansas City.

Kentucky: *Examination.* Louisville, Dec. 10-12. Sec., Dr. Russell Teague, 620 South Third St., Louisville 2.

Louisiana: *Examination and Reciprocity.* New Orleans, Dec. 6-8. Sec., Dr. Edwin H. Lawson, 930 Hibernia Bank Bldg., New Orleans 12.

Maine: *Examination and Reciprocity.* Portland, Nov. 13-14. Sec., Dr. Adam P. Leighton, 192 State St., Portland.

Maryland: *Examination.* Baltimore, Dec. 11-14. Sec., Dr. Lewis P. Gundry, 1211 Cathedral St., Baltimore 1.

Massachusetts: *Examination.* Boston, Jan. 15-18. Sec., Dr. Robert C. Cochrane, State Office Bldg., Boston.

Mississippi: *Reciprocity.* Jackson, December. *Examination.* Jackson, June. Asst. Sec., Dr. R. N. Whitfield, Old Capitol, Jackson.

Nebraska:* *Examination.* Omaha, June 17-19. Director, Mr. Husted K. Watson, Room 1009, State Capitol Bldg., Lincoln 9.

New Hampshire: *Examination and Reciprocity.* Concord, March 13-14. Sec., Dr. John S. Wheeler, 107 State House, Concord.

New Mexico:* *Examination and Reciprocity.* Santa Fe, Nov. 19-20. Sec., Dr. R. C. Derbyshire, 227 East Palace Ave., Santa Fe.

North Carolina: *Reciprocity.* Charlotte, Jan. 14. Asst. Sec., Mrs. Louise J. McNeill, 716 Professional Bldg., Raleigh.

North Dakota: *Examination and Reciprocity.* Grand Forks, Jan. 2-5. Sec., Dr. C. J. Glaspel, Grafton.

Ohio: *Examination and Reciprocity.* Columbus, Dec. 18-20. Sec., Dr. H. M. Platter, 21 West Broad Street, Columbus 15.

Oklahoma:* *Reciprocity.* Oklahoma City, Dec. 7-8. *Examination.* Oklahoma City, June 11-12. Sec., Dr. E. F. Lester, 813 Braniff Building, Oklahoma City.

Oregon:* *Reciprocity and Examination.* Portland, January. Ex. Sec., Mr. Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

Pennsylvania: *Examination.* Philadelphia, Jan. 7-10. Act. Sec., Mrs. Marguerite G. Steiner, Box 911, Harrisburg.

Rhode Island:* *Examination.* Providence, Jan. 3-4. Administrator, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

South Carolina: *Examination and Reciprocity.* Columbia, Dec. 11-12. Sec., Mr. N. B. Heyward, 1329 Blanding St., Columbia.

South Dakota:* *Examination.* Sioux Falls, Jan. 21-22. Ex. Sec., Mr. John C. Foster, 300 First National Bank Bldg., Sioux Falls.

Texas:* *Examination and Reciprocity.* Fort Worth, Dec. 6-8. Applications for reciprocity must be complete and on file at least thirty days prior to the December meeting, and applications for examination must be complete and on file at least ten days prior to the meeting date. Sec., Dr. M. H. Crabb, 1714 Medical Arts Bldg., Fort Worth 2.

Utah: *Reciprocity.* Salt Lake City, Nov. 20. *Examination.* Salt Lake City, July 11-13. Director, Mr. Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

Vermont: *Examination and Reciprocity.* Burlington, Jan. 30, Feb. 1. Sec., Dr. F. J. Lawliss, Richford.

Virginia: *Examination and Reciprocity.* Richmond, Dec. 5-7. Address: Secretary to the Board, 631 First St., S.W., Roanoke.

Washington:* *Examination and Reciprocity.* Seattle, Jan. 14-16 and Jan. 12. Sec., Mr. Edward C. Dohm, Olympia.

West Virginia: *Examination.* Charleston, January. Sec., Dr. Newman H. Dyer, State Office Building No. 3, Charleston 5.

Wisconsin:* *Reciprocity.* Jan. 9. *Examination.* Madison, Jan. 8-10. Sec., Dr. Thomas W. Tormey, Jr., 1140 State Office Bldg., 1 West Wilson St., Madison.

Alaska:* On application in Anchorage, Fairbanks, Juneau and other towns. Sec., Dr. W. M. Whitehead, 172 South Franklin St., Juneau.

Guam: *Subject to Call.* Act. Sec., Dr. S. F. Provencher, Agana.

Hawaii: *Examination.* Honolulu, Jan. 14-15. Sec., Dr. I. L. Tilden, 1020 Kapiolani St., Honolulu.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Colorado: *Examination and Reciprocity.* Dec. 5-6, Lincoln and Denver. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver 18.

Florida: *Examination.* Gainesville, Nov. 10. Sec., Dr. M. W. Emmel, University of Florida, Box 340, Gainesville.

Oklahoma: *Examination.* Oklahoma City, April 19-20. Sec., Dr. E. F. Lester, 813 Braniff Bldg., Oklahoma City.

Oregon: *Examination.* Portland, Dec. 1. Dr. Earl M. Palett, Sec., State Board of Higher Education, Eugene.

South Dakota: *Examination.* Vermillion, Dec. 7-8. Sec., Dr. Gregg M. Evans, 310 E. 15th St., Yankton.

Washington: *Examination.* Seattle, Jan. 9-10. Sec., Mr. Edward C. Dohm, Olympia.

Wisconsin: *Examination.* Milwaukee, Dec. 1 and April 6. Sec., Dr. W. H. Barber, 621 Ransom St., Ripon.

Alaska: *Examination and Reciprocity.* Anchorage and Juneau, first week of February, April, June, August and November. Sec., Dr. C. Earl Albrecht, Box 1931, Juneau.

---

*Basic Science Certificate required.

GOVERNMENT SERVICES

ATOMIC ENERGY COMMISSION

AEC Awards Research Contracts.—The U. S. Atomic Energy Commission has announced the award of 20 unclassified life science research contracts in the fields of medicine and biology to universities and private institutions. In the medical sciences eight contract renewals for one year were awarded to allow for continuation of research already in progress. The following new contracts were awarded:

Cedars of Lebanon Hospital, Los Angeles: Chemical Studies on Connective Tissues of Animals Aged Prematurely by *Irradiation* (Assessment of Biochemical Age), Harry Sobel, Ph.D.

University of Colorado, Denver: A Study of the Combined Action of Certain Chemical Inhibitors of Metabolism with X-Radiation and Other Ionizing Radiations on the Growth of *Certain* Transplantable Malignant Tumors, Richard W. Whitehead and Raymond R. Lanier.

University of Illinois, Chicago: A Study on the *Effects* of Intragastric Irradiation with Beta Rays from Ruthenium^{106}–Rhodium^{106} in Patients with Malignant Disease, Armand Littman.

AIR FORCE

Air Force Residency Training.—Since July 1, 1956, a total of 180 U. S. Air Force physicians have entered residency training. Of this number, 154 are receiving their training in civilian hospitals and 26 are in training in military hospitals. At present, 23 physicians have been approved for residency training beginning in 1957, 14 in civilian hospitals and 9 in military hospitals. The Air Force has openings in almost all the clinical specialties for residency training beginning in July, 1957. In addition, a total of 155 Air Force physicians are taking sponsored internships, 96 in civilian hospitals and 59 in military hospitals.

NAVY

Rear Admiral Pugh Accepts University Position.—Rear Adm. Lamont Pugh, retired, surgeon general of the Navy from 1951 to 1955, has accepted a position as university physician at George Washington University, Washington, D. C. In his new position, he will deal mostly with the ailments that may beset the university students. Admiral Pugh was also commanding officer of the Naval Medical Center at Bethesda, Md., prior to his recent retirement from active service.

PUBLIC HEALTH SERVICE

Fluoridated Water Supplies.—The Public Health Service reported on Oct. 28 a marked increase in the number of people drinking fluoridated water to help protect children's teeth against decay. The latest tabulation shows that fluoridated drinking water is now furnished in this country to one-fourth of the people using public water supplies. During the first nine months of 1956, communities with a combined population of 6 million started fluoridating their water. In 1946 fluoridation was used in only 12 communities with a total population of 328,000. About 1,400 cities and towns with a total population of over 30 million people were using fluoridation at the end of September, 1956. Among the larger cities adopting this preventive dental health measure are Chicago; Philadelphia; Baltimore; Washington, D. C.; Pittsburgh; Cleveland; Milwaukee; San Francisco; St. Louis; and Buffalo.

Establish Center for Aging Research.—The Surgeon General, Dr. Leroy E. Burney, has announced the establishment of a Center for Aging Research in the National Institutes of Health, of which Dr. G. Halsey Hunt, at present associate chief of the Public Health Service bureau of medical services, has been appointed director.

The new center is a part of the Public Health Service's program to coordinate and accelerate all of its activities in the field of aging. The primary objective of the new program is to support additional research into the mechanisms involved in aging. A first activity will be to aid universities, medical schools, and other research organizations in establishing comprehensive research centers on aging, to be supported in part by research grants from the National Institutes of Health.

Creation of a Center for Aging Research in the Public Health Service is in line with the program developed by the federal government through the Federal Council on Aging and the member departments and agencies to coordinate all activities associated with the problem of aging.

Marion B. Folsom, Secretary of Health, Education, and Welfare, said, "There are more than 12 million people in this country today who are over the age of 65; by 1970, there will be more than 18 million. Many of our older citizens have special health problems. It is important that more be done to help solve these problems—to help older persons to greater independence and self-sufficiency and a life more free of disease and disability."

New Director of Clinical Center.—The surgeon general has announced the assignment of Dr. Jack Masur, Washington, D. C., as director of the Clinical Center at the National Institutes of Health in Bethesda, Md. Dr. Masur, who supervised the planning and building of the Clinical Center, assumed his new duties Nov. 1. The Clinical Center, which is said to be the largest facility of its kind in the world for research in the major diseases, was officially opened in July, 1953, and present facilities are about to be expanded to permit more research in neurological and cardiac surgery. Nearly 5,000 patients from all over the United States have been admitted to the center for study and treatment. It is the responsibility of the director of the Clinical Center to plan and use the facility so that patients will receive the best in medical care and, at the same time, the research programs will be carried forward with maximum effectiveness. Dr. Masur, a native of Augusta, Ga., entered the commissioned corps of the Public Health Service in 1943. Since 1951 he has been chief of the bureau of medical services in the surgeon general's office. He is president of the American Association of Hospital Consultants, a trustee of the American Hospital Association, and a member of the Joint Commission on Accreditation of Hospitals.

Four-Year Study of Cerebral Palsy and Mental Retardation.—Awards of more than $700,000 for a four-year study of the causes of cerebral palsy and mental retardation have been made to Yale University School of Medicine, New Haven, Conn., and to Brown University, Providence, R. I., the surgeon general of the Public Health Service has announced. These awards mark the beginning of a research program that, during the next 10 to 20 years, will attempt to identify factors responsible for cerebral palsy, mental retardation, blindness, and deafness.

Brown and Yale universities are the first of a dozen or more institutions that are expected to join this program. Yale's grant for the first year is $107,799; Brown's is $97,633. The surgeon general said plans contemplate that more than 1 million dollars yearly will be awarded to medical institutions under the program of the National Institute of Neurological Diseases and Blindness.

When the full roster of participating medical institutions has been achieved, it is expected that more than 6,000 persons will be studied annually. Mothers, infants, and children will be studied over a period of several years. The data to be collected by the participating medical institutions will include complete family history, pregnancy and prenatal histories, a detailed account of events at birth, and a complete physical and psychological history of each child during his initial stay at the hospital. Infants who show signs of stress, defects in development, or neurological problems will be selected for follow-up and will receive periodic psychological and neurological examinations. It is expected that these studies will clarify the role of heredity, brain injury and brain hemorrhage, lack of oxygen, difficulty in breathing, prenatal and postnatal infections, and anemia of the newborn in the development of neurological disorders.

The National Institute of Neurological Diseases and Blindness of the National Institutes of Health will analyze all data obtained by the cooperating medical centers and will submit the findings to each participating institution. The study at the Yale University School of Medicine will be under the general direction of Dr. Gilbert H. Glaser, and the project at Brown University will be directed by Dr. Eric Denhoff.

DEATHS

Elliott, B. Landis ✠ Kansas City, Mo.; born in St. Louis Dec. 18, 1890; Washington University School of Medicine, St. Louis, 1919; associate clinical professor of medicine (neurology) at the University of Kansas School of Medicine, Kansas City, Kansas: specialist certified by the American Board of Psychiatry and Neurology; past-president of the Jackson County Medical Society, and in 1942 received that organization's merit award for outstanding service to the Community Health League of Missouri: in 1936 vice-president of the Central Neuropsychiatric Association: in 1931 secretary, and in 1932 president, of the Missouri-Kansas Neuropsychiatric Society: vice-chairman, Section on Nervous and Mental Diseases, 1936-1937, American Medical Association; fellow of the American Psychiatric Association; member of the Kansas City Academy of Medicine, Kansas City Southwest Clinical Society, and the Missouri Society for Neurology and Psychiatry; served as chief of staff, St. Joseph Hospital, and head of the psychiatric department, St. Mary's Hospital; member of the staffs at St. Luke's, Trinity Lutheran, Menorah, Neurological, Research, and Kansas City General hospitals; in 1920 was with the Red Cross in Finland, and for this service was awarded the Order of the White Rose by the government of Finland; died in Lisbon, Portugal, Sept. 8, aged 65, of coronary thrombosis, while on a vacation in Europe.

Walsh, Jeremiah Henry ✠ Corning, N. Y.; born in Curtis, N. Y., Aug. 6, 1870; Niagara University Medical Department, Buffalo, 1894; an associate member of the American Medical Association, serving as a member of its House of Delegates from 1917 to 1924, a trustee from 1924 to 1933, and for many years secretary of the Board of Trustees; president of the Chicago Medical Society, 1924-1925; member of the Illinois State Medical Society; for many years practiced in Chicago, attending surgeon at the City of Chicago Municipal Tuberculosis Sanitarium, St. Anne's Hospital, and Norwegian-American Hospital, and consulting surgeon, St. Anthony de Padua Hospital: during World War I member of the exemption board, Selective Service; at one time a member of the board of education of Chicago; died Oct. 12, aged 86, of arteriosclerosis.

Muller, Henry Richard, Pittsfield, Mass.; Cornell University Medical College, New York City, 1913; at one time taught pathology at Johns Hopkins University in Baltimore; formerly associated with the Rockefeller Institute in New York City: served on the staffs of St. Luke's Hospital in Cleveland, Vassar Brothers Hospital in Poughkeepsie, N. Y., and the Doctors Hospital in New York City; on the staffs of the W. B. Plunkett Memorial Hospital in Adams and the Hillcrest Hospital, where he died Aug. 18, aged 69, of prolonged effects of injuries received in an automobile accident.

Alexander, Joseph H. ✠ Zavalla, Texas; Memphis (Tenn.) Hospital Medical College, 1891; an honorary staff member of Angelina County Hospital and Memorial Hospital, Lufkin: examining surgeon for the Southern Pacific Lines in Texas and Louisiana; died in Cleveland Aug. 25, aged 86, of coronary thrombosis.

Arkin, Archie Abraham ✠ Des Moines, Iowa; University of Manitoba Faculty of Medicine, Winnipeg, Manitoba, Canada, 1932; member of the American Academy of General Practice: on the staffs of Mercy and Iowa Lutheran hospitals; died in St. Mary's Hospital, Rochester, Minn., Aug. 14, aged 55, of pulmonary edema and myocardial infarction.

Baker, Cecil Heber ✠ St. Louis: St. Louis University School of Medicine, 1910; veteran of World War I; on the staff of the Lutheran Hospital: died Sept. 4, aged 69, of coronary thrombosis.

Barrett, Van F. ✠ Lakeview, Ohio: Western Reserve University Medical Department, Cleveland, 1895; died in the Mary Rutan Hospital, Bellefontaine, Aug. 31, aged 87, of coronary thrombosis.

Bentley, Norman Philip ✠ St. Paul; Syracuse University College of Medicine, Syracuse, N. Y., 1909: member of the American Academy of General Practice; veteran of World War I; died Aug. 6, aged 68, of carcinoma of the lung.

Borow, Henry ✠ Bound Brook, N. J.: University of Arkansas School of Medicine, Little Rock, 1931; one of the founders and staff member of the Bound Brook Hospital, where he was a member of the board and where he died Sept. 9, aged 51, of lymphosarcoma.

Carter, Ross Stagg, San Diego, Calif.: Johns Hopkins University School of Medicine, Baltimore, 1910: past-president of the San Diego County Medical Society; died Aug. 26, aged 73, of pulmonary emphysema and heart disease.

Collinson, Thomas Jefferson ✠ Tupper Lake, N. Y.; Queen's University Faculty of Medicine, Kingston, Ontario, Canada, 1908; died in the Royal Victoria Hospital, Montreal, Quebec, Canada, Aug. 14, aged 73, of myocardial infarction.

Curtis, Stephen Horace ✠ Troy, N. Y.: Albany (N. Y.) Medical College, 1915; in 1946 member of the House of Delegates of the American Medical Association, member of the American Society of Clinical Pathologists; fellow of the American College of Physicians; on the staffs of the Leonard and Samaritan hospitals; died Aug. 20, aged 62, of coronary occlusion.

Devol, Edmund, New York City; New York Homeopathic Medical College and Hospital, New York City, 1896; an associate member of the American Medical Association; died in the Roosevelt Hospital Aug. 28, aged 83.

Doran, William Thomas, New York City; Long Island College Hospital, Brooklyn, 1905; fellow of the American College of Surgeons; formerly on the faculty of University and Bellevue Hospital Medical College: an associate member of the American Medical Association; surgical director of Columbus Hospital; for many years on the staff of Bellevue Hospital; died in the Metropolitan Hospital Sept. 10, aged 78, of injuries received in an automobile accident.

Douglas, George R. ✠ Valparaiso, Ind.: the Hahnemann Medical College and Hospital, Chicago, 1901; for many years county health officer; served as health officer of Valparaiso; past-president of the Porter County Medical Society; on the staff of the Porter Memorial Hospital, where he died July 8, aged 82, of coronary occlusion.

Duggan, LeRoy Bates ✠ Houston, Texas; University of Texas School of Medicine, Galveston, 1928; clinical associate professor of medicine, Baylor University College of Medicine; specialist certified by the American Board of Internal Medicine; member of the American College of Gastroenterology and the American Psychosomatic Society; fellow of the American College of Physicians; veteran of World War II; on the staff of Hermann Hospital, where he died Aug. 27, aged 55.

Foster, Daniel Parsons, Detroit; Harvard Medical School, Boston, 1922; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; an associate member of the American Medical Association; for many years head of the division of metabolic diseases at Henry Ford Hospital, where he died Aug. 21, aged 64, of bronchopneumonia.

Foust, Earl Harland ✠ Eustis, Fla., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; member of the Michigan State Medical Society; died Aug. 27, aged 78, of pneumonia.

Ginsburg, Abraham ✠ New York City; Long Island College Hospital, Brooklyn, 1910; veteran of World War II; died Aug. 23, aged 68.

Glass, Bernard Robert, Napa, Calif.; Creighton University School of Medicine, Omaha, 1937; interned at the U. S. Marine Hospital, San Francisco; senior physician and surgeon on the staff of the Napa State Hospital in Imola; died in the Parks Victory Memorial Hospital Sept. 3, aged 45, of hemorrhage due to peptic ulcer.

✠ Indicates Member of the American Medical Association.

Golley, Kyle Wood ⊕ Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1921; on the staffs of St. Joseph's Hospital and the Mercy Hospital, where he died Sept. 6, aged 59, of cerebral hemorrhage.

Gordon, Adolphus Noble, Chicago; Meharry Medical College, Nashville, Tenn., 1894; on the staff of the Provident Hospital; died in the Albert Merritt Billings Hospital Sept. 22, aged 85, of post prostatectomy hemorrhage.

Guajardo, Javier G., Laredo Texas (licensed in Texas in 1926), died Aug. 21, aged 92, of bronchopneumonia and arteriosclerotic heart disease.

Hampton, John Erwin ⊕ Newport, Tenn.; University of Tennessee Medical Department, Nashville, 1902; veteran of World War I and the Spanish-American War; died in the Valentine-Shults Hospital Sept. 2, aged 78, of nephritis and heart disease.

Hankins, Thornton Wilson ⊕ Swoope, Va.; Medical College of Virginia, Richmond, 1906; died Aug. 31, aged 74, of cerebral embolism and arteriosclerosis.

Hasner, Robert Bain ⊕ Royal Oak, Mich.; Rush Medical College, Chicago, 1908; past-president of the Oakland County Medical Society; an honorary staff member of the board of Highland Park (Mich.) General Hospital; served on the executive medical board of the William Beaumont Hospital, where he died Sept. 16, aged 72, of cerebral thrombosis.

Heaton, Thomas Henry ⊕ Cambridge, Mass.; Tufts College Medical School, Boston, 1898; died Aug. 4, aged 81, of cerebral hemorrhage.

Henry, Albert Cleaver ⊕ Wickford, R. I.; Hahnemann Medical College and Hospital of Philadelphia, 1930; past-president of the Washington County Medical Society; served as president of the staff of South County Hospital in Wakefield, and the Roger Williams General Hospital in Providence; school physician; died Aug. 15, aged 52, of coronary occlusion.

Hill, Reginald Lindsey, Lyndonville, Vt.; University of Vermont College of Medicine, Burlington, 1923; served as health officer; on the staff of the Brightlook Hospital in St. Johnsbury; died Aug. 9, aged 57, of heart disease.

Horrigan, Thomas Francis ⊕ Detroit; Wayne University College of Medicine, Detroit, 1945; interned at the City of Detroit Receiving Hospital; formerly a resident at the Providence Hospital; served in the Medical Corps, Army of the United States; on the staff of the Metropolitan Hospital; died in Oscoda Aug. 13, aged 36, of coronary thrombosis.

Howard, Isaac B. ⊕ Williamson, Ga.; Atlanta School of Medicine, Atlanta, 1909; for many years member of the county board of education; died Aug. 10, aged 81, of coronary thrombosis.

Howell, William Erastus ⊕ Morristown, Tenn.; Tennessee Medical College, Knoxville, 1903; past-president of the Tennessee Medical Association; died Aug 28, aged 76.

Hubbard, Ralph George, Detroit; University of Michigan Medical School, Ann Arbor, 1926; an associate member of the American Medical Association; served on the faculty of his alma mater, on the staffs of the Woman's and Florence Crittenden hospitals, and the Mount Carmel Mercy Hospital, where he died Aug. 31, aged 57, of arteriosclerosis.

Jameson, Robert Emmet ⊕ Phoenix, Ariz.; Milwaukee Medical College, Milwaukee, 1912; member of the Iowa State Medical Society; for many years practiced in Davenport, Iowa, and was secretary of the Scott County Medical Society; died Aug. 12, aged 76, of asthmatic bronchitis and emphysema.

Jenkins, Charles Rivington, Daytona Beach, Fla.; Long Island College Hospital, Brooklyn, N. Y., 1899; member of the Medical Society of the State of New York; died July 8, aged 77, of reticulum cell sarcoma.

Johnston, George P. ⊕ Cheyenne, Wyo.; Medical College of Ohio, Cincinnati, 1891; member of the House of Delegates of the American Medical Association, 1903, 1917-1918, 1923, 1926-1929, 1931, 1933-1935, and 1937-1948; fellow of the International College of Surgeons and the American College of Surgeons; died Sept. 18, aged 93, of heart disease.

Jordan, Thomas Cook, Jr. ⊕ Milledgeville, Ga.; Medical College of Georgia, Augusta, 1945; member of the Medical Association of Georgia and the American Academy of General Practice; formerly an officer in the Medical Corps, Army of the United States, died Aug. 13, aged 39, of coronary thrombosis.

Kaplan, Maurice Isadore ⊕ Chicago; Washington University School of Medicine, St. Louis, 1910; assistant professor of radiology at the Chicago Medical School; member of the Radiological Society of North America; from 1914 to 1921 health officer, department of health; for many years on the staff of the Mount Sinai Hospital, where he died Sept. 6, aged 68, of pyelonephritis and diabetes mellitus.

Katzoff, Manuel, Norfolk, Va.; Baltimore Medical College, Baltimore, 1906; died in the Leigh Memorial Hospital Aug. 14, aged 71, of cancer of the stomach,

Keating, Francis Raymond, Philadelphia; Medico-Chirurgical College of Philadelphia, 1905; an associate member of the American Medical Association; for many years a medical referee for the Prudential Insurance Company; died in the Pennsylvania Hospital Sept. 9, aged 76, of heart disease.

Kellogg, Frederic Sherlock, Oxford, Miss.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; member of the Medical Society of the State of Pennsylvania; an associate member of the American Medical Association, for many years practiced in Pittsburgh, where he was on the staff of the Western Pennsylvania Hospital; served as a member of the Lenawee County (Mich.) draft board; died in the Oxford Hospital July 31, aged 84, of heart disease.

Kidder, Frank Woodman Kinsman, Los Angeles, College of Physicians and Surgeons, Los Angeles, 1909, an associate member of the American Medical Association; specialist certified by the American Board of Radiology, member of the Radiological Society of North America and the American College of Radiology; died in the Hospital of the Good Samaritan Aug. 1, aged 69, of coronary heart disease and arteriosclerosis.

Kirov, Konstantin Vesselin ⊕ Chicago; Leopold Franzens-Universitat Medizinische Fakultät, Innsbruck, Austria, 1947; died in the Wesley Memorial Hospital July 27, aged 33, of Hodgkin's disease.

Knoch, Norbert Henry ⊕ Glenwood Springs, Colo ; Denver and Gross College of Medicine, Denver, 1910, on the staffs of St Joseph's and Childrens hospitals in Denver, and the Valley View Hospital; died July 27, aged 67, of heart disease.

Krieger, Henry Arthur, Madison, S. D., Bennett Medical College, Chicago, 1909; died June 27, aged 74, of cerebral thrombosis and diabetes mellitus.

Langley, John Wesley, Granby, Mo.; College of Medicine and Surgery (Physio-Medical), Chicago, 1890, died Aug 17, aged 89, of coronary disease.

Lavin, Francis Charles ⊕ Carbondale, Pa.; Georgetown University School of Medicine, Washington, D. C, 1932, veteran of World War II; associated with St. Joseph's Hospital, where he died Aug. 10, aged 50, of a heart attack.

Leeson, Ernest Edward, Inverness, Fla., College of Physicians and Surgeons of Chicago, 1894; died in the Veterans Administration Hospital, Bay Pines, July 6, aged 84, of arteriosclerotic heart disease.

Lewi, William Grant, Glendale, Calif.; Albany (N. Y.) Medical College, 1892, an associate member of the American Medical Association; member of the Medical Society of the State of New York; died Aug. 18, aged 86, of cerebral vascular accident.

Llewellyn, Charles Elroy ⊕ Richmond, Va.; Medical College of Virginia, Richmond, 1916; member of the American Academy of General Practice; on the staff of the Johnston-Willis Hospital, died while on a vacation, Aug. 24, aged 63, of injuries received in an automobile accident near Parlin, Colo.

McClendon, John Irvin, Russell Springs, Ky.; University of Louisville Medical Department, Louisville, 1907, died Aug. 3, aged 76.

McCracken, Earl Joseph ⊕ Whittier, Calif.; University of Louisville (Ky.) School of Medicine, 1947; interned at the Kentucky Baptist Hospital in Louisville, Ky.; served in the U. S. Air Force Reserve; on the staff of the Beverly Community Hospital in Montebello; died July 17, aged 42, of arteriosclerosis.

McGuire, Frank James ✠ Guilford, Conn.; Boston University School of Medicine, Boston, 1937; veteran of World War II; served on the staff of Hospital of St. Raphael in New Haven; died Sept. 1, aged 46, of sarcoma of the lung.

McKenna, Joseph Lawrence ✠ Grand Rapids, Mich.; University of Michigan Medical School, Ann Arbor, 1926; veteran of World War II; served on the staff of St. Mary's Hospital; died Aug. 25, aged 54, of pulmonary embolism.

Martin, John Reboe Bitner, Gap, Pa.; Miami Medical College, Cincinnati, 1903; died Aug. 21, aged 75, of acute coronary occlusion.

Meeker, Irving Avard, Upper Montclair, N. J.; New York Homeopathic Medical College and Hospital, New York City, 1898; an associate member of the American Medical Association; medical examiner, board of education, town of Montclair; died at Columbia-Presbyterian Medical Center, New York City, Sept. 15, aged 83, of cerebral thrombosis.

Melchiorre, Nicholas Vincent ✠ Philadelphia; Temple University School of Medicine, Philadelphia, 1930; on the staff of St. Agnes Hospital, where he died Aug. 28, aged 50, of acute myocardial infarction.

Meyers, Lloyd Rogers, Cumberland, Md.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1915; member of the Medical and Chirurgical Faculty of Maryland; on the staffs of the Memorial and Sacred Heart hospitals; died Aug. 11, aged 65, of coronary thrombosis.

Miller, Lewis Israel ✠ Denver; Loyola University School of Medicine, Chicago, 1918; served as president of the Colorado Hospital Service; on the staffs of the Beth Israel, St. Anthony, and Childrens hospitals; died Aug. 13, aged 61, of acute coronary thrombosis.

Morgan, Burnice Earl ✠ Asheville, N. C.; University of Tennessee College of Medicine, Memphis, 1917; member of the American Academy of General Practice; for many years chairman of the Buncombe County Board of Education; past-president of the Buncombe County Medical Society and of the Tenth District Medical Society; veteran of World War I; on the staffs of the St. Joseph's, Aston Park, and the Memorial Mission hospitals; for a time a member of the board of trustees of Asheville-Biltmore College; died Aug. 14, aged 62.

Morgan, Loftus E., Baton Rouge, La.; Trinity Medical College, Toronto, Ontario, Canada, 1890; died at Our Lady of the Lake Hospital Aug. 21, aged 91, of coronary occlusion.

Neff, Robert Lee ✠ Joplin, Mo.; University Medical College of Kansas City, Mo., 1894; an associate member of the American Medical Association; fellow of the American College of Surgeons; on the staff of St. John's Hospital, where he died Aug. 23, aged 86, of coronary occlusion.

Orton, George Lee, Rahway, N. J.; Jefferson Medical College of Philadelphia, 1909; an associate member of the American Medical Association; past-president of the Union County Medical Society; formerly member of the board of health; on the staff of the Rahway Memorial Hospital of which he was a founder; died Aug. 11, aged 78, of coronary artery disease and heart block.

Payne, Richard Johnson ✠ St. Louis; St. Louis University School of Medicine, St. Louis, 1913; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology; on the staffs of the Barnes, St. Louis Children's, and Missouri Baptist hospitals; died Aug. 28, aged 68, of coronary occlusion.

Rand, Paul King, Alexandria, La.; Tulane University School of Medicine, New Orleans, 1913; past-president of the Louisiana State Medical Society, of which he was a member; veteran of World War I; at one time on the faculty of the University of Wisconsin in Madison; past chief of staff, Baptist Hospital; on the staff of St. Frances Cabrini Hospital; died Aug. 7, aged 68, of heart disease.

Rayhill, John Wayland, Utica, N. Y.; Long Island College Hospital, Brooklyn, 1906; served on the staff of the Faxton Hospital, where he died Aug. 8, aged 79.

Robinson, William Herbert, Roaring Spring, Pa.; College of Physicians and Surgeons, Baltimore, 1907; died in Altoona June 28, aged 74, of arteriosclerotic heart disease.

Rogers, James Virgil ✠ Cairo, Ga.; Emory University School of Medicine, Emory University, 1921; member of the Grady County School Board; member of the American Academy of General Practice; died in Thomasville Aug. 25, aged 64.

Saunders, Robert Ritchie, Philadelphia; Jefferson Medical College of Philadelphia, 1892; an associate member of the American Medical Association; specialist certified by the American Board of Ophthalmology; died in the Jefferson Medical College Hospital Aug. 19, aged 84.

Schutzman, Benjamin Maxwell, Detroit; Detroit College of Medicine and Surgery, Detroit, 1930; died July 24, aged 50.

Seibert, David Allen, Los Angeles; Barnes Medical College, St. Louis, 1909; formerly associated with the U. S. Veterans Bureau; died in the Veterans Administration Hospital Aug. 7, aged 74, of pneumonia.

Sharkis, David, Philadelphia; Hahnemann Medical College and Hospital, Philadelphia, 1932; on the staff of the Hahnemann Medical College and Hospital; died in the Albert Einstein Medical Center, Northern Division, Aug. 20, aged 63, of hypertension.

Sharp, Jacob Sevier, La Follette, Tenn.; Tennessee Medical College, Knoxville, 1899; died Aug. 25, aged 84, of heart disease.

Simpson, Russell Edwin, Jr. ✠ Pasadena, Calif.; Stanford University School of Medicine, San Francisco, 1942; member of the American Psychiatric Association; veteran of World War II; on the staff of the Collis P. and Howard Huntington Memorial Hospital; died Aug. 6, aged 40.

Sims, Wayne Waldo Conway ✠ Seattle; University of Colorado School of Medicine, Denver, 1929; specialist certified by the American Board of Preventive Medicine; member of the American Academy of Dermatology and Syphilology; clinical assistant professor of public health and preventive medicine at the University of Washington School of Medicine; veteran of World War II; director of the venereal disease division of the Seattle-King County Department of Health; died Aug. 23, aged 52.

Smiley, Henry Chandler, Redondo Beach, Calif.; Denver and Gross College of Medicine, Denver, 1905; formerly practiced in Torrance, where he organized the Torrance District Health Center, which he served; died in Los Angeles July 15, aged 74, of heart disease.

Sneidman, George Irving ✠ Hartford, Conn.; Medical College of Virginia, Richmond, 1936; veteran of World War II; member of the American Academy of General Practice; on the staff of the Mount Sinai Hospital; died in the Hartford Hospital Aug. 23, aged 57.

Soper, Richard Watts, Hendersonville, N. C.; Sioux City College of Medicine, Sioux City, Iowa, 1898; formerly on the staff of the Veterans Administration Hospital in Augusta, Ga.; died in the Swannanoa unit of the Veterans Administration Hospital in Oteen Sept. 1, aged 87, of carcinoma of the prostate.

Thornton, Mary Bickings ✠ Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1904; emeritus professor of anatomy at her alma mater; member of the American Academy of General Practice; died in the Hospital of the Woman's Medical College of Pennsylvania Sept. 7, aged 75.

Thurston, Asa, Taylorsville, N. C.; University of Maryland School of Medicine, Baltimore, 1909; member of the Medical Society of the State of North Carolina; served in the state legislature; on the staff of the Alexander County Hospital; died in the Rowan Memorial Hospital, Salisbury, Aug. 24, aged 73, of arteriosclerosis.

Warinner, Junius Ernest ✠ Richmond, Va.; Johns Hopkins University School of Medicine, Baltimore, 1916; served overseas during World War I; member of the Richmond Academy of Medicine; for many years on the staff of the Grace Hospital; member of the board of directors of the Richmond Memorial Hospital; died Sept. 4, aged 64, of a heart attack.

Way, Lewis Richard, Traverse City, Mich.; Northwestern University Medical School, Chicago, 1922; veteran of World War II; died July 8, aged 58, of myocardial infarction and coronary arteriosclerosis.

FOREIGN LETTERS

BELGIUM

Poliomyelitis.—The Minister of Public Health and Family appointed a permanent commission of experts in poliomyelitis to consider the problems concerning this disease. As compared with the United States, with its annual morbidity rate in the last 10 years varying from 18 to 37 cases per 100,000 inhabitants, the morbidity rate during this same period in Belgium was from 3 to 11 cases per 100,000 inhabitants. A serologic survey was conducted to determine what age groups are most susceptible as a guide to a rational vaccination program.

Physicians and the Government.—The conflict between government and physicians reached a culmination, and the government's attempt to establish socialized medicine was thwarted. More than 80% of the physicians refused to obey the directions according to which the forms of the official social insurance should be used. Establishing a strictly medical organization in opposition to the governmental organization of sickness insurance, the Belgian Medical Federation on Oct. 1 established the National Service of Physicians. The physicians have refused to become mere clerks. The aim of the National Service of Physicians is to assure that all persons with modest income receive the necessary medical care, with their personal rights taken into consideration. The members of this association agree to respect the scale of fees established by the National Medical Service. The beneficiaries of the National Medical Service are all persons, whether insured or not, whose yearly gross income does not exceed 100,000 francs, with an increase of 25,000 francs for a wife and 10,000 francs for each additional dependent. By means of this purely medical association and without governmental interference, the medical needs of the population will be met.

Tuberculous Meningitis.—Durieu and co-workers reported to the Belgian Society of Scientific Studies that 87 patients with tuberculous meningitis, in 65 of whom the diagnosis was bacteriologically confirmed, were given intraspinal injections of streptomycin every day for three months and then injections every two days for three additional months. Intramuscular injections were then given for six months. The patients who did not respond to this treatment were given suboccipital or intraventricular injections. There were 42 survivors with a follow-up period of two to six years. Eight patients had relapses, and 4 of these recovered; 23 of the survivors were able to resume their work. Complete deafness was observed in 9 and severe disturbances of the labyrinth in 12 patients.

FRANCE

Hepatosiderosis in Alcoholics.—J. Lereboullet and co-workers, at the meeting of the Medical Society of the Hospitals of Paris on June 29, stated that hepatosiderosis is especially frequent in alcoholics (50%) and still more so in those with chronic hepatic cirrhosis (66%). Nevertheless, 35% of the patients with hepatosiderosis are not alcoholics and have livers that are histologically normal. The authors stress the fact that massive hepatosiderosis is found in an almost constant proportion of the population irrespective of the presence of cirrhosis or alcoholism but occurs more frequently in men. Such patients also have an excess of ferric pigments in the spleen, pancreas, myocardium, kidneys, and testes. It is not known whether this represents an early stage of diffuse hemochromatosis.

Idiopathic Auricular Fibrillation.—Maurice and co-workers, at a meeting of the Medical Society of the Hospitals of Paris on June 15, reported a series of 90 patients with idiopathic auricular fibrillation. The fibrillation was poorly tolerated in 85 of the patients in that, in addition to various functional disturbances, it gave rise to cardiac insufficiency in 34 patients, to left ventricular or global hypertrophy in 57, and to electrocardiographic anomalies in 38. The cardiac index was generally diminished, and in some patients this diminution was extreme. After digitalization, stabilization with quinidine under cover of anticoagulants was attempted in 68 patients and was successful in 47. In most of these there was no recurrence of the fibrillation. The return to sinus rhythm almost invariably led to spectacular improvement and almost always to a complete disappearance of the functional disturbances and the cardiac insufficiency and even of the radiological and electrocardiographic anomalies. On the other hand, the condition of the patients whose fibrillation continued generally deteriorated. It is therefore justifiable to make a cautious attempt to stabilize idiopathic auricular fibrillation with quinidine.

Brachyesophagus.—E. Roviralta, at the meeting of the Society of Pediatrics of Montpellier on April 23, showed that, for reasons principally anatomic and clinical, brachyesophagus in the nursling is almost always acquired. Its prevention should be based on a periodic examination of children presenting partial thoracic displacement of the stomach who are undergoing medical treatment. Gastric retention should be corrected by pylorotomy or section of adhesions. Phrenicectomy has been used successfully in the hemorrhagic form. Transhiatal fixation of the cardia should be reserved, as a prophylactic measure, for patients in whom gastric drainage or paralysis of the diaphragm has failed or for those in whom there are special indications.

Hypoproteinemia.—At the same meeting, J. Chaptal and co-workers said that hypoproteinemia in infants results in severe malnutrition, severe hepatic steatosis, and a decline in serum albumin and gamma globulin levels. Treatment is difficult, and the course is often unfavorable. The lack of certain amino acids interferes with the synthesis of many digestive, hepatic, and renal enzymes and gives rise to disturbances of pigmentation, xerophthalmia, perleche, and erythredema polyneuropathy. Chromatographic study of the blood and the urine demonstrates extreme plasma deficiency of amino acids and polyaminoaciduria linked apparently to an acquired enzyme disturbance of the renal tubule. In the course of hypoproteinemia due to hepatitis, a drop in the albumin level is associated with an increased gamma globulin level. The blood and urinary chromatograms show an abundance of amino acids poorly used by the altered liver in the plasma and a suprarenal polyaminoaciduria. In one patient with essential hypoproteinemia, the nitrogen balance was positive but inadequate. The balance was maintained only when 600 mg. of protein per kilogram of weight was given intravenously every day. The child died of shock after a transfusion. In both deficiency hypoproteinemia and essential hypoproteinemia, the protein deficiency was estimated at about 10 gm. of protein per kilogram of body weight.

Renal Diabetes.—M. Bernheim and co-workers (*Pédiatrie* 11:161, 1956) state that renal diabetes is a rare constitutional disease characterized by glycosuria without hyperglycemia, a normal glucose tolerance test, and absence of any disorders in urinary elimination of phosphorus and amino acids. True renal diabetes is characterized by a lowering of the Tm_G (maximum tubular excretory capacity for glucose) and abnormal glomerular filtration; pseudorenal diabetes occurs in subjects with a normal Tm_G. The possibility of a transformation of renal diabetes into diabetes mellitus, though improbable, requires further and prolonged observation of the cases.

Idiopathic Renal Acidosis.—Jeune and Charrat (*Pédiatrie* 11:295, 1956) state that idiopathic renal acidosis is of interest clinically because it corresponds to a certain number of cases of readily curable abiotrophy in infants, and theoretically because it poses the problem of the renal mechanisms in acidobasic regulation. No cause can be recognized with certainty, but one must think either of a particular sensitivity to vitamin D or of an immaturity of the renal tubules. The clinical aspect is most frequently that of a persistent anorexia and an arrest in growth occurring after the

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

age of 6 months, with sudden episodes of acidosis. There is a discrepancy between blood acidosis and urinary alkalosis. The latter seems to be due to the incapacity of the proximal tubules to reabsorb bicarbonate ions, the functions of the distal tubules remaining intact.

Cystinuria.—C. A. Schiavini (*Pédiatrie* 11:181, 1956) states that modern methods of investigation of amino acid metabolism allow a differentiation between early cystinuria (or preferably lysinocystinuria) and cystinosis. Cystinosis, a rare disease, is recognized in infants by anorexia, arrest of growth, thirst, bouts of fever, and rickets, and in its late form by dwarfism, vitamin-resistant rickets, photophobia, and chronic renal disease. Hypophosphatemia and at times acidosis, increase of the alpha-2-globulins, and generalized hyperaminoaciduria may be present.

Viral Respiratory Disease.—R. Sohier and co-workers (*Pédiatrie* 11:631, 1956) studied the frequency of acute infectious bronchitis and pneumonitis caused by viruses, with use of serologic tests for their identification. These tests included the use of cold agglutinins, Streptococcus MG agglutinins, and complement-fixation tests for the ornithosis group of viruses, A and B influenza virus, the adenoviruses, and Q fever. In 26 of 175 patients under 6 years with bronchopneumonia and 23 of 61 such children from 6 to 15 years, the infection was due to a virus. In patients with other diseases positive reactions were found only in 1.1% of those under 6 and 3.3% of those from 6 to 15 years of age. The positive reactions in many cases ruled out the diagnosis that had been made on admission.

Cutaneous Lesions Following BCG Vaccination.—R. Bastin and co-workers (*Pédiatrie* 11:681, 1956) report that in two children, aged 3 and 3½ years, a generalized exanthema developed over five weeks after BCG vaccination. These eruptions in the first child showed some similarity with polymorphous erythema, and in the second they had a morbilliform appearance. The first child had a leukocyte count of 50,000 per cubic millimeter, with a predominance of lymphocytes, and the second had a leukocyte count of 14,000, with an eosinophilia. The authors believe the eruptions to be due to primary infection with the BCG.

IRELAND

Tuberculosis.—As a result of improved treatment, the death rate from tuberculosis fell from 91 in 1949 to 34 in 1954 per 100,000 population. The number of new cases reported fell from 7,552 in 1949 to 6,266 in 1954. The health department recommends that young persons who show a negative reaction to the tuberculin test should be offered BCG vaccination, particularly if they live in rural districts and wish to move into the towns or go abroad. Many Irish immigrants to Great Britain contract tuberculosis. In the last five years, 1,300 returned from Great Britain to be treated for tuberculosis.

SWITZERLAND

Chlorpromazine and the Biliary Passages.—In 3 to 5% of the patients treated with chlorpromazine, jaundice appears. This complication is, to a certain extent, independent of the dose of the drug, but when it appears it is almost always in the third or fourth week of treatment. Its severity and duration are variable. The clinical findings are those of biliary obstruction, despite the absence of any obstruction. Errors of diagnosis are frequent and often lead to operative exploration, which shows the principal biliary passage to be empty and free of obstruction. Needle biopsy of the liver shows the biliary canaliculi to be gorged with thick, dark bile, with the formation of a kind of biliary thrombi, while the hepatic cells appear to be intact. The spontaneous course of the jaundice is toward a cure, either rapid or after weeks or months. The pathogenesis of chlorpromazine jaundice has not yet been elucidated. F. Besson (*Schweiz. med. Wchnschr.* 86: 1020, 1956) concluded that chlorpromazine provokes in most patients a prolongation of the time of closing of the sphincter of Oddi, an irregular outflow of the bile in slow spurts, and a delay in the emptying of the gallbladder. It is therefore a matter of the creation of a genuine biliary dyskinesia of a special type, similar to cystic dystonia or atony, which appears even after cholecystectomy. There is apparently a hypertonia of the sphincter of Oddi in relation to the weakness of the biliary flow. The biliary emptying is therefore almost routinely disturbed by chlorpromazine, but without evident effect in most patients. Clinically, this effect of chlorpromazine helps to explain the digestive sluggishness and stubborn constipation that occur so often in the course of treatment, and it is associated with the reduction of peristalsis and of the secretory activity of the gastrointestinal tract.

Diuretic Effects of Certain Polysaccharides.—It appears from experiments made by Desaulles and Meier (*Schweiz. med. Wchnschr.* 86: 1060, 1956) that in intact rats subjected to overloading with water or saline solution, certain polysaccharides possess the property of inducing general diuresis and an elimination of sodium increasing in intensity with the sodium concentration of the overload. Potassium excretion is not modified. These effects are met with only in normal animals. They can be antagonized by aldosterone and disappear in animals deprived of their adrenals. It seems unlikely that the mechanism of action of these substances is due to a direct effect favoring the elimination of salt and water and that the effect disappears as a result of the increase of renal elimination of sodium and the passage of increased quantities of extracellular sodium into the interior of the cell as a result of adrenalectomy. As these special types of action, observed after the injection of polysaccharides, bacterial among others, cannot be reproduced with the help of any known hypo-physial or adrenal factor, it must be concluded that these effects are either the result of a complex inhibition of one or more of these factors or that they are due to some unknown factor.

Radioactive Isotopes.—J. H. Muller (*Med. et hyg.* 14: 351, 1956) showed that it is possible to inject strong preparations of radioactive zinc in the form of quasi-colloidal suspensions of an insoluble sulfur into the abdominal cavity of patients affected by severe peritoneal carcinosis of ovarian origin. In 1949, Muller used radioactive gold (Au^{198}), in a colloidal form, for intraperitoneal and intrapleural injections for the same purpose. Its half-life of 2.69 days is ideal for applications of this kind. In 1950, the author extended the indication for peritoneal administration of Au^{198} colloid (with artificial hydroperitoneum of about 400 cc. in patients without ascites) to all patients with ovarian cancer whatever their degree of operability, as a supplement to standard postoperative radiotherapy. This combined radiological treatment has already been applied to about 130 patients, with results that are proving more and more clearly favorable. In fact, in this group of patients, all those with operable lesions (stage 1) have remained free from relapses and only 20% of the patients in stage 2 have had relapses. Intravenous injection of Au^{198} colloid results in a quasi-specific accumulation of radioactive particles at the level of the reticuloendothelial elements of the liver and the spleen. In one patient, Muller obtained, by means of such injections, the dramatic disappearance of an enormous lymphosarcomatous hepatosplenomegaly, and in various other patients a partial regression radiosensitive cancerous hepatic metastases.

UNITED KINGDOM

The *Minister's Annual* Report.—In his report on the National Health Service in England and Wales for 1955, the Minister of Health noted that the total cost of the service was 1,386 million dollars, an increase of 61.6 million dollars over the previous year. Of this sum, over 1,086 million dollars was met by the exchequer out of sums voted by Parliament. Only 100.8 million dollars was provided by contributions from the National Insurance Fund. This is equivalent to 12 cents out of each weekly total contribution for men, and it represents only a small fraction of the full weekly contributions paid by, or in respect of, insured persons. There is still a popular belief among the so-called working classes that their weekly contributions to the National Insurance Fund defray the entire cost of the National Health Service, which many of them use so freely. The minister's report shows that the contributions from the National Insurance Fund covered only 7% of the total gross cost of the service. Other sources of income were as follows: 19.6 million dollars paid by patients for dental treatment and dentures; 14 million dollars paid by patients for eyeglasses; and 13.8 million dollars paid by patients for drugs and appliances. This last sum is made up of the 14 cents that must be paid by each patient on every prescription dispensed for him under the service.

The hospital and specialist service costs 778.4 million dollars, which is just over 56% of the entire cost of the service. Hospital waiting lists, numbering only 453,000 persons, were the lowest recorded since the inauguration of the service. This decrease was most marked in the field of tuberculosis; the waiting list fell by 54% (from 3,017 to 1,387). In most areas, there are now no waiting lists for patients with tuberculosis. In spite of the fact that there was no increase in the number of hospital beds, the number of inpatients rose by 18,000, reaching a total of 3,600,000. The striking improvement in the tuberculosis situation is illustrated by comparing the 1955 figures with those of 1949. In the latter year, there were 19,908 deaths from tuberculosis, of which 17,559 were respiratory; 52,041 reported cases, of which 44,480 were respiratory; and a waiting list of 10,986. However, in 1955 there were only 6,492 deaths from tuberculosis, of which 5,837 were respiratory; 38,134 reported cases, of which 33,580 were respiratory; and a waiting list of 1,387. This vast improvement has made it possible to bring to an end the Swiss Sanatorium Scheme introduced in 1951 to relieve the strain on the sanatoriums in this country. Under that plan, 1,025 patients were sent to Switzerland for an average stay of six months at a total cost of just over 1.036 million dollars.

The number of full-time and part-time consultants rose by 2.1%, thus bringing the total to 6,650. These range from 801 in general medicine down to 44 in neurosurgery. The number of administrators fell by about the same percentage, but they still number over 28,000. The general medical service costs 147 million dollars. The number of principals in general practice under the service rose slightly, making a total of 18,832, of whom just under 7,000 practiced without an assistant or a partner. Of those in partnership, practically 10,000 were in partnerships of two or three, and only 289 were in partnerships of six or more. More than half of the assistants in general practice were 30 years of age or under, and nine were 76 years of age and over. Only 1,545 general practitioners attended refresher courses during the year. The pharmaceutical service cost 120.4 million dollars. During the year, 226,116,091 prescriptions were dispensed by pharmacists; this was 7,500,000 more than in the previous year. The average cost per prescription was 61 cents. The number of spectacles supplied was 4,500,000, and about 170,000 new and repaired hearing aids were supplied. The total number of persons now using hearing aids is 428,520.

Hospital Helicopter Landing Grounds.—Four hospitals in Cornwall are to have helicopter landing grounds in order to reduce the time taken in getting injured persons to the hospital by the R.A.F. Search and Rescue Service. This service, which was originally designed to rescue air crews that crashed in the sea, is now being used to an ever-increasing extent to rescue anyone in difficulty at sea or stranded on rocks. As Cornwall is one of the favorite playgrounds of England, with a coast line as noted for its dangers as for its beauty, every summer a number of persons lose or almost lose their lives in such accidents as falling down cliffs or getting stranded on rocks at high water. In the past, such persons, when rescued by helicopter, have first had to be taken to the helicopter base and then transferred to an ambulance to be taken to the hospital.

Vivisection.—The annual return of experiments on living animals, published by the Home Office, shows that 2,476,201 experiments were performed during 1955. The number of persons licensed to perform such experiments was 5,161, of whom 1,443 did not perform any during the year. About 87% of the experiments were performed without anesthetics. These consisted of inoculations, external applications, modifications of the animal's diet or environment, or the administration of a drug or toxin. In the study of cancer, 292 licensees performed 148,175 experiments. For public health purposes or for the diagnosis of disease, 180,303 experiments were made; these were usually simple inoculations. Over a million experiments were performed in the course of preparing and testing substances intended for use in the treatment of disease in man or animals.

Meals for Older Persons.—In September, 1955, a service of domiciliary meals for older persons was inaugurated in Rotherham. The first nine months of the service has been reported by Donaldson and Wales. (*M. Officer* 96:93, 1956). The plan is based on the assumption that every home has normally a certain amount of staple groceries and provisions and that if these were supplemented by the daily purchase of extra foodstuffs a full and varied diet could be provided for the patient. Of the 23 older persons selected for the program, all were over 80 years of age, lived alone, and had an income balance of less than $5.60 a week after the payment of rent and other weekly expenses. Twenty-one of the patients were housebound and 12 were bedfast. In each case the attendant at the home was given the sum of 88 cents a week with which to purchase supplementary food for five of the week's dinners. She was also given specimen menus as a general guide in achieving a balanced diet, but the patients were encouraged to suggest items for dinner so that their individual likes and dislikes could be respected. The general practitioners in charge of the patients were informed and consulted about the diet. At the end of the first nine months of the program, reports were obtained from the attending physicians; these showed a general improvement in the well-being of the patients. During the period, a total of 3,049 meals were served at a cost of $732. The two great advantages of the plan are that it provided for the personal predilections of the older persons and provided this by an existing service already operating in the home.

Postgraduate Courses for General Practitioners.—An account of a conference on postgraduate courses, organized by the College of General Practitioners, was published in *Research Newsletter* (no. 12) of the college. The Dean of University College Hospital London, reported that at his hospital they had been considering the appointment of general practitioners to various departments of the hospital and medical school. They were asking general practitioners to attend ward rounds and discuss with the students how, in their practice, patients might appear to them first. The dean agreed with the suggestion that a general practitioner should serve on the appointments committee, which selects students for the hospital. His hospital favored the suggestion that there should be a chair of general practice in each medical school.

Dr. J. G. McCrie, dean of the faculty of medicine at the University of Sheffield, reported that there were two representatives of the local faculty of the College of General Practitioners on the postgraduate committee of the university. This committee was responsible for arranging courses for general practitioners in and around Sheffield. In Sheffield it had been the custom for several years to provide for general practitioners, throughout the two winter terms, weekly ward rounds and clinical demonstrations. In response to 500 or 600 notices sent out, about 30 physicians usually attended. These were mostly the same persons each year. Evening lectures in pediatrics were popular. A general practitioner nominated by the local faculty of the college sat as a member of every selection committee. An arrangement was made by the professor of social medicine, in collaboration with the local division of the British Medical Association, for the attachment of final-year students to selected general practitioners for two weeks each. The program is voluntary, but few students fail to take advantage of it. The attachment was on a nonresidential basis, and Dr. McCrie considered that, if plans could be made that allowed for the student's residing in the physician's house, the program would be of much greater value. He wondered whether the setting up of a general practitioner unit attached to a university might not give a somewhat artificial view of general practice. No lectures were given in the university on general practice, but such questions as those about the structure of the National Health Service, statutory certificates, and medical ethics were included in the syllabus of certain classes. The local clergy have suggested that students should be instructed in cooperation with the clergy in the treatment of the sick.

Dr. Charles Newman, dean of the Postgraduate School of London, said that for general practitioners clinical evenings had proved successful originally but that the same people tended to come every time and that eventually attendance had fallen off. Lectures had not been satisfactory, as general practitioners did not find them clinical enough. Discussion panels were useful as an occasional activity, but they were not flexible enough to form a regular weekly feature. Lecture-demonstrations had not proved successful nor had general ward rounds. In the end the best technique had proved to be to give special demonstrations in the wards: teaching over the bed and contrasting the condition of one patient, such as a patient with asthma with consequent bronchitis, with that of another patient, such as a patient with bronchitis showing bronchial spasm.

Dr. E. C. Warner, the dean of Charing Cross Hospital, described the plan in operation there. Students in the final six months of their clinical period are sent out to selected general practitioners for a course of instruction in general practice. A very important feature is that, in almost every case, the student lives with the physician during this time. It was found that the ideal period was three weeks. While the students are with the general practitioners, they examine as many patients as possible, both in the office and in the patients' homes. The patients rarely objected to the presence of the student. Although at first the students were averse to the program, they have become enthusiastic about it, and some have voluntarily arranged to stay with the physician for a fourth week. The cost of board and lodging is covered in part by the student and in part by the medical school.

WORLD HEALTH ORGANIZATION

Whooping Cough.—Although whooping cough is still often considered to be of relatively little importance, it kills more babies during the first year of life than all the other common diseases of childhood combined (Annual Epidemiological and Vital Statistics Report, vol. 9, no. 6, Geneva, World Health Organization, 1956). Deaths from whooping cough have shown a marked and continuous drop in the past 50 years, but the decrease has been much less than that observed in the death rates for other communicable diseases such as diphtheria, scarlet fever, and measles. Moreover, the drop in mortality began before the discovery of effective means of protection, and this fact has not been satisfactorily explained. Despite fewer deaths, the number of cases has not diminished and the disease affects as many people as ever. Whooping cough also appears to be unique among the infectious diseases, in that it usually strikes and kills more girls than boys. Recently there has been a rapid rise in reported cases of whooping cough from certain countries and territories, but this could be attributed to better medical reporting rather than to a real increase in the prevalence of the disease. The statistics collected indicate that whooping cough affects a greater proportion of young children in southern (Egypt, Portugal, Italy) than in northern countries.

Accident Prevention.—The World Health Organization regional committee for Europe reports that, in Great Britain, 45 people on an average lose their lives every day as the result of accidents, 16 in some form of travel (14 on the road, 1 on the railways, and 1 in air or water transport), 5 at some place of work (2 in factories, 1 in coal mines, and 2 in farms, quarries, and other places of work), and 24 in and around the home (17 inside the home and 7 in ordinary pursuits around the home). In the Netherlands also, traffic accidents are not the most frequent cause of accidental death. In Italy, the pattern is similar. The average daily accident toll is 44 killed (7 at work, 20 in travel, and 17 at home and elsewhere). In Finland in 1955, 36% of all deaths in the age group 1 to 14 years were due to accidents. About half of these were drownings (unlike the pattern in Great Britain, where drownings are rare). In Germany, accidents in the home account for more than 30% of all fatal accidents. In Yugoslavia, among hospital patients, almost 20% of the deaths result from accidents. Rapid industrialization in that country has led to a serious increase in accidents.

In Norway, efforts are being made to reduce the number of drownings in open disused wells, and legislation that will make owners responsible has been drafted. In France during the last 15 years or so, burns and scalds have become less frequent but falls out of windows and from high structures have become more frequent. A new and growing hazard in the home is poisoning. On the one hand, there are insecticides and corrosive liquids that are kept *in many* homes, particularly on farms; on the other, there are dangerous medicines that the manufacturers have tried all too successfully to make attractive with bright wrappings, pretty colors, and sugar coating on the pills. In Iceland, drowning has been decreasing as a cause of death. Swimming lessons are compulsory, and by use of the Icelandic hot springs many bathing pools have been made in which even the smaller children are happy to test their courage and skill. Traffic accidents are being reduced in Austria by getting children to take part in controlling the traffic. In that country, children are also being brought into factories and other places where danger is present. An account was given of a large block of flats where the automatic elevator was used by children but did not cause any accidents. A committee of children was responsible for keeping it clean and in good running order.

The following points were stressed: 1. Information about fatal accidents is much more complete and accurate than the records of injuries that do not result in death. Accidental deaths are relatively frequent in children under 5 years of age and in persons over 60. 2. Fatal accidents have become relatively more frequent in recent years because of the decrease in deaths from infectious diseases. There is also an absolute increase due to hazards associated with increasing mechanization. 3. The available statistics deal almost exclusively with fatal accidents, but *the nonfatal accidents, which are perhaps 100 times as common*, give rise to a great amount of suffering, disability, and economic loss. 4. There is an urgent need for more intensive studies of nonfatal accidents, as the evidence suggests that their pattern differs from that of fatal accidents. For example, fatal injuries in the home tend to cluster around persons in the extremes of life, but the nonfatal accidents affect principally the housewife and the adolescent children. 5. Special attention should be given to preventive measures. Houses and household equipment should be designed for safety, especially electrical appliances and sources of heat. Children and elderly people should be protected from dangerous drugs, corrosive liquids, and other hazards. The committee laid great stress on education as the greatest single measure in the prevention of accidents. This includes the careful training of children at home and in school and especially giving them a sense of responsibility for their own safety. It comprises also the training of teachers and parents through films, radio, television, posters, and booklets.

Dr. Sutter Resigns.—Dr. Victor A. Sutter, assistant director-general in charge of advisory services in the World Health Organization, in Geneva, has resigned his position in order to accept an appointment as Minister of Public Health and Social Assistance in his own country, El Salvador. Dr. Sutter, a member of the WHO staff since 1950, studied at the National University of San Salvador and at Johns Hopkins University in Baltimore.

Regional Director for Europe.—The regional committee for Europe elected Dr. P. J. J. van de Calseyde as its nominee for the post of World Health Organization regional director for Europe. The post became vacant as the result of Dr. Begg's death earlier this year. Dr. Van de Calseyde's name will be sent for endorsement to the WHO executive board in January. At present he is director-general of health at the Ministry of Health, Brussels, Belgium.

Resistance of Insects to Insecticides.—Leadership in the stimulation and coordination of research throughout the world on the problem of resistance of insects to insecticides should be assumed by the World Health Organization, according to a group of experts. Great alarm has been caused by the appearance of resistance to such insecticides as chlorophenothane (DDT) among certain species of insects. In the housefly, resistance to insecticides is becoming universal. It is also of frequent occurrence in the body louse and exists locally in several species of mosquitoes. WHO should coordinate the different lines of research on the problem of resistance already being undertaken in laboratories scattered throughout the world; stimulate further research, particularly concerning the physiology, biochemistry, and genetics of the insects concerned; assure the publication and exchange of information and research results; and facilitate the procurement of qualified personnel and funds for research. Standard techniques should be adopted or developed for detecting and measuring resistance, and WHO should circulate information concerning new insecticides as it becomes available.

Rapid Diagnosis of Human Influenza Infection from Nasal Smears by Means of Fluorescein-Labeled Antibody. Ch'ien Liu. Proc. Soc. Exper. Biol. & Med. 92:883-887 (Aug.-Sept.) 1956 [Utica, N.Y.].

In the study of influenzal infection in ferrets by means of fluorescein-labeled antibody, it was possible to make a rapid diagnosis of influenzal infection during the acute stage of illness by detecting specific viral antigen in the desquamated nasal epithelial cells and macrophages in the nasal smears. This paper reports the application of this method to influenzal infection in humans. The method was applied to 20 patients during an outbreak of influenza A-prime infections, to 44 during an outbreak of influenza B, and to 23 patients with various acute febrile or respiratory illnesses. With a rise of fourfold or greater in titer of hemagglutination-inhibition (HI) antibody during convalescence or else the recovery of virus from human nasal washings used as diagnostic criteria for influenzal infection, the use of fluorescent antibody had an accuracy of 71% in an influenza A-prime and 38% in an influenza B epidemic. One false-positive diagnosis was encountered among 23 noninfluenzal infections. The use of labeled antibody on smears of nasal washings is less sensitive than the HI test, but a positive diagnosis could be made on the day the specimens were collected, while the HI test requires a delay of 10 to 14 days for collection of convalescent serum.

Hypertensive Pulmonary Vascular Disease. D. Heath and W. Whitaker. Circulation 14:323-343 (Sept.) 1956 [New York].

The authors describe six cases of severe pulmonary hypertension in four women between the ages of 21 and 58, one 24-year-old man, and one 12-year-old girl. The condition was complicated by a ventricular septal defect, Eisenmenger's complex, patent ductus arteriosus, atrial septal defect, and mitral stenosis, respectively, in the five adult patients; the child had idiopathic pulmonary hypertension. The clinical picture was dominated by symptoms and signs characteristic of pulmonary hypertension, which often masked underlying cardiac anomalies. Symptoms of severe pulmonary hypertension were breathlessness on exertion, frequent cough and colds, chest pain of anginal type, blueness of the lips and nails, and abdominal distention and swelling of the ankles due to congestive cardiac failure. Hemoptysis, hoarseness, jaundice, syncopal attacks, and palpitation occurred less commonly. Signs associated with pulmonary hypertension were giant "a" waves in the jugular venous pulse, a parasternal heave, a systolic lift over the right ventricular outflow tract, a palpable second sound in the pulmonary area that was loud and closely split on auscultation, a Graham Steell murmur, and a pulmonary systolic click. In addition, central and peripheral cyanosis, clubbing of the fingers, jaundice, signs of congestive cardiac failure, and cardiac murmurs occurred. The electrocardiogram usually showed clockwise rotation of the heart and the ventricular pattern of right ventricular hypertrophy. On radiological examination there was evidence of right ventricular hypertrophy, increased prominence of the pulmonary artery and its main branches, and decreased peripheral pulmonary vascular markings. Angiocardiography revealed a dilated pulmonary artery and a coppicing effect in the small branches of the pulmonary vascular tree. The flow of dye through these dilated vessels was abnormally slow. It allowed abnormal flows to be visualized and previously unrecognized cardiac defects to be demonstrated. Cardiac catheterization showed pulmonary artery blood pressures approaching or exceeding systemic pressures and occasionally revealed intrinsic cardiac defects.

Five of the patients died and autopsy was performed in all of these. The definitive pathological changes in the pulmonary vasculature were a distinct muscular media with two elastic membranes in the pulmonary arteriole and medial hypertrophy in the muscular pulmonary artery. Frequently in these vessels there was abnormal proliferation of intimal fibrous tissue with partial or complete occlusion of the lumen, adventitial fibrosis, and medial necrosis. Occasionally there was aneurysmal dilatation of thin-walled branches of the muscular pulmonary arteries.

Patients with pulmonary artery blood pressures chronically elevated to levels approaching or exceeding systemic pressures demonstrate a distinct clinicopathological entity for which the term hypertensive pulmonary vascular disease is proposed.

Peroral Maintenance Treatment of Pernicious Anemia with Vitamin B_{12} and Intrinsic Factor. H. Olsen. Ugesk. læger 118:895-897 (Aug. 2) 1956 (In Danish) [Copenhagen, Denmark].

Twelve patients with pernicious anemia who were treated from the start with vitamin B_{12} and intrinsic factor by mouth and reacted well to the treatment were examined after from 10 to 34 months of treatment. The blood status was satisfactory in all cases, and the neurological symptoms present at the beginning of treatment had disappeared. No new neurological symptoms attributable to the hematological disease had developed.

Constrictive Pericarditis: A Review and Long-Term Follow-Up of 78 Cases. J. C. Dalton, R. J. Pearson Jr. and P. D. White. Ann. Int. Med. 45:445-458 (Sept.) 1956 [Lancaster, Pa.].

Dalton and associates reviewed the clinical aspects of 78 patients with constrictive pericarditis, of whom 59 were males and 19 females. Sixty-five of the patients were operated on, and 42 of these are still living. Six have been followed for over 20 years, 10 for over 10 years, and 11 for over 5 years. All of the patients followed over 20 years are living normal, unrestricted lives. There were several operative deaths among 61 patients who underwent 71 operations. Of the seven patients who were operated on more than once, two died. Excellent results were obtained by operation in 32 of 64 patients and fair results in 13 (14 operations); no improvement resulted in 5 of the patients. The two groups of patients who obtained excellent and fair results were compared with regard to their preoperative status. The only positive correlation was that 29 of the 32 patients in the "excellent result" group were in sinus rhythm preoperatively, while three had atrial fibrillation. Of the 13 patients classified as having "fair results," only five were in sinus rhythm preoperatively, while eight had either atrial flutter or fibrillation as their basic rhythm. It is interesting that all six patients who had been followed for over 20 years and who are considered as having excellent results had normal rhythm preoperatively and at last examination in 1955.

Duration of symptoms, heart size, and calcification of the pericardium were compared in the two groups and showed no significant differences. Dyspnea on exertion, ankle edema, and abdominal swelling, in that order, are the most frequent complaints at the onset and as the constrictive pericarditis progresses. Among the physical findings, hepatomegaly and distention of the neck veins remain the most common. A systolic blood pressure above 130 mm. Hg was found in only one patient preoperatively, whereas wide pulse pressures were not rare (greater than 50 mm. Hg in 9% of cases). Systolic blood pressures commonly rose postoperatively, but no patient became seriously hypertensive. Cardiac enlargement was present in one-half of the patients. Cardiac pulsations were diminished in four-fifths but were fluoroscopically normal in the other fifth of the patients. Abnormal electrocardiograms were present in every pa-

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1917 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

tient; the T waves were abnormal in 100% and the P waves in 72% of those with normal rhythm. Atrial arrhythmias were common, having been found in 34 of the 78 patients; fibrillation was identified in 27, being constant in 19, while flutter occurred in 3, in 2 of whom it changed to fibrillation. Calcification was noted in the pericardium in 60% of the patients.

Serum Hepatitis Following Dental Procedures: A Presentation of 15 Cases, Including Three Fatalities. F. E. Foley and R. N. Gutheim. Ann. Int. Med. 45:369-380 (Sept.) 1956 [Lancaster, Pa.].

Various skin-penetrating procedures have been known to be followed by serum hepatitis. The members of the house staff of the Rochester General Hospital, Rochester, N.Y., first became aware of the appearance of hepatitis after dental procedures in 1952. The charts of all patients treated at that hospital for infectious or serum hepatitis between June, 1953, and June, 1955, were studied. Of 57 patients with viral hepatitis, 7 contracted serum hepatitis after blood or plasma transfusions. The remaining 50 patients ordinarily would have been considered as having infectious hepatitis. Fifteen of these patients, however, gave a history of a dental injection during the preceding one to six months and are referred to as the dental serum hepatitis group. These dental injections consisted of the injection of procaine during the process of extracting teeth in 13 patients and the filling of teeth in 2 patients. Two of the 15 patients had received penicillin injections at the same time as the procaine injections. The ages of the patients ranged from 18 to 71 years. The onset of illness in 14 patients was insidious in nature. The remaining patient had a rather acute onset. Malaise, fatigue, and anorexia, alone or in various combinations, were the first symptoms in all but three of the patients. Nausea and abdominal pains were next in frequency. Laboratory data obtained in the 15 patients were characteristic of viral hepatitis. Three fatalities occurred in this group. Heat sterilization of needles, syringes, and instruments is essential to prevent the spread of serum hepatitis. The danger of the use of multiple injection bottles is emphasized.

Lupus Erythematosus, Discoid and Systemic: One Disease. M. F. Allende. Postgrad. Med. 20:254-259 (Sept.) 1956 [Minneapolis, Minn.].

Allende presents clinical, histopathological, experimental, and therapeutic evidence to support the concept that chronic discoid lupus erythematosus and systemic lupus erythematosus are merely variants of a single disease. Chronic discoid lupus erythematosus should be considered as the mildest form of systemic lupus erythematosus. Patients with chronic discoid lupus erythematosus should be warned about the dangers of actinic radiation, of the use of potentially toxic drugs, of minor infections, and of the indiscriminate removal of so-called foci of infection. They should be checked at regular intervals with physical examinations supplemented by determination of the sedimentation rate of the erythrocytes, by complete blood counts, and by urinalysis. These measures should be supplemented by a search for the L. E. phenomenon if imminent dissemination is suspected.

Agammaglobulinemia. S. Aarseth. Tidsskr. norske lægefor. 76: 505-507 (Aug. 1) 1956 (In Norwegian) [Oslo, Norway].

A case of primary idiopathic agammaglobulinemia in a man aged 41 is the first in an adult observed in Norway. The patient manifested, from early childhood on, a tendency to infections of the respiratory tract. He had the usual childhood diseases, recurrent bilateral purulent otitis, and from the age of 16 on a purulent sinusitis. He has had pneumonia at least 14 times. There are bronchiectases with type 3 pneumococci. A purulent meningococcus meningitis in June, 1955, yielded to intensive penicillin and sulfonamide treatment. Pneumonia shortly thereafter was successfully treated with aureomycin. In December, 1955, he had meningitis due to type 3 pneumococcus; again treatment with massive doses of penicillin and sulfonamide was effective. At this time severe diabetes of the insulin-deficient type was discovered. Agammaglobulinemia was suspected because of the patient's unusual tendency to infections. Electrophoretic examination showed the patient to be practically without gamma globulin. In agammaglobulinemia the respiratory tract is primarily exposed to infection. Bronchiectases belong in the picture. No special tendency to tuberculosis is seen. Generalized vaccinia with a fatal outcome has been noted in agammaglobulinemia, and children with this anomaly should not be vaccinated against smallpox. Prophylactically, patients with the disease can be protected against infection by the administration of gamma globulin in doses of 100 mg. per kilogram of body weight monthly; an alternative is application of an antibiotic—slow-acting penicillin—or a sulfonamide. An accumulation of infections in a patient calls for paper electrophoretic examination of the serum. It is the simplest diagnostic method for clinical use. In the case in question the combination of agammaglobulinemia, severe diabetes, and extensive bronchiectases infected with pneumococci make the long-range prognosis doubtful.

SURGERY

Adrenalectomy for Intracranial Metastases From Carcinoma of the Breast. A. Clain and A. H. Hunt. Brit. M. J. 2:627-629 (Sept. 15) 1956 [London, England].

At the Royal Marsden Hospital over 90 adrenalectomies had been performed up to the end of 1955. In only two patients were cerebral metastases clinically evident. The first patient, a 37-year-old woman, had been subjected to radical mastectomy for anaplastic carcinoma of the left breast in August, 1948. Carcinoma of the whole of the right breast, with peau d'orange and a retracted nipple and extensive involvement of the axillary nodes was found in January, 1951. Bilateral oophorectomy was performed and a course of x-ray therapy given to the right breast and glandular areas. The local progress of the disease was arrested. Thereafter the condition remained unchanged until November, 1954. At that time personality changes were evident. Radiograms of the skull showed expansion and destruction of the pituitary fossa, presumably from erosion by growth. The left lung contained multiple metastases. A large quantity of ascitic fluid was present. She was given daily doses of 1,000 mg. of testosterone propylpropionate for three days and 50 mg. of cortisone for five days. Her diabetes insipidus was treated with pitressin. On Nov. 23, it was felt that she was fit for surgery. Both adrenal glands were removed at one operation. She made a slow but steady recovery. Her mental symptoms cleared up and the diabetes insipidus gradually improved, though she still required small doses of pitressin. She has remained reasonably well up to the time of this report, 22 months after operation.

The second patient, a 40-year-old woman, also had cerebral metastases after a right radical mastectomy for anaplastic carcinoma. Her neurological state likewise recovered rapidly after removal of the right adrenal, the left adrenal having been removed at the time of bilateral oophorectomy seven days earlier. The authors conclude that bilateral gonadectomy and adrenalectomy is at present the only treatment of value for patients with intracranial metastases from cancer of the breast. It should be attempted when possible, because these patients are otherwise doomed. Hypophysectomy, whatever its place may be in the treatment of the other manifestations of metastatic breast cancer, has no place in the palliation of cerebral metastases.

Observations of Human Adrenal Cortical Deficiency with Special Reference to Replacement Therapy with Cortisone. A. G. Hills, H. A. Zintel and D. W. Parsons. Am. J. Med. 21:358-379 (Sept.) 1956 [New York].

Adrenalectomies have been performed in the University of Pennsylvania Hospitals as an experimental therapeutic approach to severe hypertensive disease. The studies presented deal particularly with two aspects, namely, (1) whether surgically produced primary adrenal deficiency in man differs in kind or in degree from spontaneously occurring Addison's disease, and (2) to what extent cortisone (with or without supplementation with desoxycorticosterone) falls short of furnishing entirely satisfactory maintenance therapy for adrenal-deficient man. The results of a five-year study of 44 patients subjected to adrenalectomy are presented together with observations of 9 patients in whom Addison's disease occurred spontaneously. Cortisone, often supplemented by a small quantity of desoxycorticosterone, was given as replacement therapy. Steroid therapy is indispensable for the survival of persons who have been subjected to total adrenalectomy, but some patients with Addison's disease and some subtotally adrenalectomized persons can survive and maintain well-being without it. Such patients apparently enjoy a nearly normal basal rate of adrenal cortical secretion. The survival value of this secretion can be estimated as corresponding to the amount of steroid that will just maintain a totally adrenalectomized man in good general health (that is, assuming adequate salt intake, about 30 mg. of orally administered cortisone acetate daily, supplemented by 1 mg. of desoxycorticosterone acetate given by the buccal route.

Few patients with Addison's disease are totally destitute of endogenous adrenal cortical secretion. Approximately 5% of the total amount of adrenal cortical tissue normally present will produce enough secretion to sustain life under ordinary circumstances. This quantity of surviving tissue has, however, practically no capacity to increase its basal hormone output, and a patient without ample cortical reserve is imperiled by any stress unless exogenous hormone can then be supplied. Cortisone can maintain the life of totally adrenal-deficient persons indefinitely and can restore strength and well-being, but it does not provide a balanced replacement for the missing adrenal cortical secretion, of which cortisone and hydrocortisone are only partial constituents. There is no truly "physiological" quantity of cortisone, that is, there is no dose of cortisone that, on long-term administration to adrenal-deficient patients with or without a small supplement of desoxycorticosterone, will not be accompanied by certain signs of hypoadrenalism or certain manifestations of hypercortisonism or both. The signs of hypoadrenalism commonly encountered in such patients are melanosis, impairment of water diuresis, unresponsiveness to hypoglycemia, and sometimes salt waste, azotemia, and hyperkalemia. The signs of hypercortisonism are polyphagia, weight gain, and impairment of glucose tolerance. No fundamental distinction can be drawn between spontaneous and iatrogenic primary adrenal cortical deficiency. The incidence of melanosis has been strikingly lower in patients rendered adrenal-deficient by surgery than in persons with spontaneous Addison's disease, but this difference can probably be ascribed to the provision of cortisone to the former group from the time of origin of the adrenal-deficient state. However, although cortisone has antipigmentary properties in adrenal-deficient persons, the adrenal cortex must contain antipigmentary factors other than cortisone and hydrocortisone. Clinically detectable regeneration of adrenal cortical tissue occurred only once in a series of 27 patients subjected to subtotal adrenal resection.

On the So-Called Abscess Cancer of the Lungs. L. Morelli and L. Di Domizio. Arch. ital. chir. 81:181-201 (No. 3) 1956 (In Italian) [Bologna, Italy].

Cavitary cancer of the lung, or abscess cancer, is a type of bronchogenic carcinoma; it is characterized by a cavity of recent formation that contains purulent necrotic material. The authors observed 12 such cases of cancer, 8 primary and 4 secondary. Among the eight primary cases, histological examination demonstrated small-cell carcinoma in six patients and polymorphous carcinoma in one. Of the four secondary forms, three belonged to the polymorphous type and one to the small-cell type. Radiological examination was useful in the general diagnosis of cavitary suppuration, but it was not so useful in the diagnosis of carcinoma. Bronchoscopy was performed in all cases. Biopsy of metastatic supraclavicular lymph nodes confirmed the clinical diagnosis. Six patients underwent surgery: one explorative thoracotomy, three pneumectomy, one lobectomy, and one pneumotomy. Ten patients were over 45 years of age, one was 43, and another was 41; there were 11 men and one woman. The symptoms, which were almost the same in all cases, included cough with little expectoration always tinged with blood, fever, and dyspnea. In some patients symptoms had been present for 12 months and in one case for two years. Surgical intervention is necessary if the combined therapy for pulmonary suppuration gives no result in from four to eight weeks, especially if the patient is over 45 years of age.

The Aggressive Treatment of Metastases. E. Wilson. M. J. Australia. 2:292-297 (Aug. 25) 1956 [Sydney, Australia].

The author believes that, while the future treatment of metastases lies more with hormonal and other methods, surgical treatment holds the first place at present. Not only is surgery advisable after metastases have been detected clinically, but there is also a place for elective reexploration to search for and to deal with metastases before they are otherwise detectable. In the absence of metastases at the primary operation, elective reexploration of the abdomen should be considered within six months in patients with carcinoma of the colon, ovary, liver, pancreas, and rectum, and slightly earlier in those with carcinoma of the stomach. In all cases in which a second operation has already been required for the eradication of a metastatic mass and where there is no evidence of any other metastasis, an elective reexploration should be strongly recommended. Supraradical surgery has a place in the early stages of certain cancers rather than in the subterminal stages of the disease. However, supraradical surgery is occasionally indicated even for palliation. A case is described in which symptoms of hepatic insufficiency were temporarily relieved by litigation of the branch of the hepatic artery to that particular lobe destroyed by the metastases. The relief was probably due to the resulting increased blood supply of the lobe that contained most of the functioning hepatic tissue.

More study should be given to (1) the effects on cancer cells of substances that stimulate the growth or metabolism of normal cells, (2) the reasons why some malignant growths do not metastasize, (3) the use in "hormone-dependent" cancers of hormone therapy and of hormone exclusion operations, especially hypophysectomy produced by both surgical and medical means, (4) the place of elective reexploration in the management of intra-abdominal and other cancers, and (5) the positions of metastases in specimens removed from patients apparently cured by surgery. Such study would provide a basis for determining the extent of the operations to be employed for various cancers.

Scalene Node Biopsy: An Analysis of 42 Cases. W. W. Yang. California Med. 85:165-166 (Sept.) 1956 [San Francisco].

Scalene node biopsy was done in 42 patients with previously undiagnosed intrathoracic lesions. The basis of the scalene node or fat-pad biopsy is that lymph nodes anterior to the scalenus anticus muscle are connected with the mediastinal nodes. Thus intrathoracic disease involving the mediastinal nodes may often be reflected in the scalene nodes. The same is true of systemic disease directly involving the mediastinal nodes. The simple scalene node biopsy hence is a biopsy of the mediastinal nodes without the necessity of entering the thorax. A definite histological diagnosis was obtained in 25 of the 42 patients. Carcinoma of the lung was detected in nine patients, metastatic tumor to the lung in eight, pulmonary tuberculosis in three, lymphoma in three, anthracosis in one, and sarcoidosis in one. Scalene node biopsy is especially useful in patients with bronchogenic carcinoma. In this disease the value of this biopsy is twofold: 1. A diagnosis may often be obtained without thoracotomy. 2. In such cases, and also in those in which the diagnosis has been made by other means, the procedure is of value in determining the prognosis. When a scalene node biopsy is positive for cancer, there has been considerable extension of the carcinoma; operability is then questionable. Complications are rare in scalene node biopsy. Hemorrhage due to injury to the jugular vein occurred in one of the patients in this series, but it was readily controlled. Scalene node biopsy is a valuable diagnostic procedure.

NEUROLOGY & PSYCHIATRY

Subarachnoid Haemorrhage Due to Intracranial Aneurysms: Results of Treatment of 249 Varified Cases. W. McKissock and L. Walsh. Brit. M. J. 2:559-565 (Sept. 8) 1956 [London, England].

A survey of 461 patients with subarachnoid hemorrhage admitted to St. George's Hospital in London up to March 31, 1954, revealed that in 249 the hemorrhages were caused by an aneurysm. The data on the 249 patients with proved intracranial aneurysm associated with subarachnoid hemorrhage are analyzed in relation to the severity of the effects of the hemorrhage and the site of the aneurysms. The results of various types of surgical treatment are compared with those of medical treatment. The frequency of associated intracerebral, intraventricular, and subdural hemorrhage is given. The frequency and time of occurrence of repeated hemorrhage is considered, and the operation of carotid ligation is discussed. Very early investigation and treatment of patients with a bleeding aneurysm seems advisable because a lower mortality has been shown to occur in cases handled in such a manner than is to be expected from the natural course of the disease. In medically treated patients with anterior communicating or middle cerebral aneurysms the natural death rate is over 90%. If even a few patients can be restored to reasonable health by surgical measures, the operative mortality rate should surely be assessed against the natural death rate of 90%, and so even a 50% operative mortality rate would be acceptable.

An Investigation of Neurosurgical Alleviation of Parkinsonism, Chorea, Athetosis and Dystonia. I. S. Cooper. Ann. Int. Med. 45: 381-392 (Sept.) 1956 [Lancaster, Pa.].

Cooper summarizes the current status of the neurosurgical treatment of several hyperkinetic disorders, particularly Parkinsonism. He reviews observations made in the course of 200 operations, 180 of which were performed for Parkinsonism. The remaining 20 were performed in patients with various other hyperkinetic disorders, which could be grouped as chorea, choreoathetosis, tension-athetosis, and dystonia musculorum deformans. Fifty-five of these operations consisted of surgical occlusion of the anterior choroidal artery; the other 145 were chemopallidectomies. The operation of anterior choroidal artery occlusion is best suited for young patients with postencephalitis Parkinsonism of long duration. It has the disadvantage of being dependent upon the vagaries of the anterior choroidal artery, but it may produce great benefit in a reasonable percentage of patients. Therefore, in selected instances, the risks of this procedure are justified.

Chemopallidectomy is of potential value in all types of Parkinsonism. Its technique has the advantage of being accurate, straightforward, and simple to execute. In fact, its simplicity could easily lead to abuse and incorrect usage. Chemopallidectomy provides an opportunity to select the correct subcortical site for destruction by the performance of an intracerebral procaine injection before the infliction of a permanently destructive lesion. Thus, the effect in a given patient can be predicted with a reasonable degree of accuracy. The risk of this operation is low, the mortality rate being less than 3%. The possibilities of lasting benefit are good—at least 70% at the present time. There is at present no cure for Parkinsonism. There is, however, the possibility of useful alleviation of many of its symptoms by neurosurgery. There is as much, if not more, justification for the neurosurgical treatment of Parkinsonism as there is for the neurosurgical treatment of intractable pain or of focal epilepsy. The approaches described are new, but their cautious and expert use will not only give relief to patients but will also increase the knowledge needed to advance the therapy of hyperkinetic diseases.

Prenatal Obstruction of the Fourth Ventricle. D. D. Matson. Am. J. Roentgenol. 76:499-506 (Sept.) 1956 [Springfield, Ill.].

Successful treatment of hydrocephalus depends upon an accurate knowledge of the location and type of obstruction to normal cerebrospinal fluid movement. Matson describes one type of hydrocephalus, namely, that due to prenatal obstruction of the foramens of Magendie and Luschka, in which the roentgenographic findings are pathognomonic. Obstruction of the normal foramens between the fourth ventricle and the surface subarachnoid pathways dating from early embryonic life falls into the category of congenital anomalies in which the earliest possible recognition is not only desirable but of the greatest importance in obtaining a satisfactory surgical result. This obstruction of the fourth ventricle has been observed at the author's clinic during the last four years in eight infants under six months of age.

Congenital obstruction of the fourth ventricle foramen should be suspected from the clinical appearance of the patient in the first months of life. The diagnosis can always be confirmed preoperatively by roentgenographic examination, including plain skull roentgenograms, ventricular air studies, and dural sinus venography. In this condition a huge cyst fills a much enlarged posterior fossa and projects downward into the cervical spinal canal as well as upward through the incisura of the tentorium. The tentorium fails to descend and is attached high on the parietal bones. There is obstructive internal hydrocephalus, which in some patients may be relieved completely by suboccipital craniectomy with excision of the cyst wall; in others it is converted to a communicating type of hydrocephalus, which must subsequently be treated by creation of a peritoneal or ureteral shunt. No surgical death occurred in the eight infants operated on at the author's clinic, but one patient died two months after operation with progressive communicating hydrocephalus complicated by convulsive seizures. Three of the remaining patients are doing well with no further treatment than wide excision of the cyst wall. In the other four patients excision of the posterior fossa cyst has had to be supplemented by spinal fluid shunting procedures to maintain normal intracranial pressure. The earliest possible recognition and definitive treatment of this lesion offers the best chance for a satisfactory result—and by satisfactory result is meant not survival, but opportunity for normal mental and motor development of the child.

Hemorrhagic Diathesis in Poliomyelitis. T. Bennike and L. C. Grandjean. Acta med. scandinav. 155:225-236 (No. 3) 1956 (In English) [Stockholm, Sweden].

Fifty-one (15%) of 349 severely paralyzed patients with poliomyelitis who were admitted to the Blegdams Hospital in Copenhagen, Denmark, during the 1952-1953 epidemic of poliomyelitis had a clinically manifest hemorrhagic diathesis in the form of bleeding into the skin, bleeding from mucous membranes and internal organs, and bleeding after tracheobronchial aspiration. The bleeding tendency was most pronounced in the most severely affected patients and occurred particularly within the first two weeks of the illness. Tracheobronchial hemorrhage predominated, but hematuria was also observed frequently. A systematic examination of 115 patients with poliomyelitis with varying degrees of paralysis revealed that 80% of the patients, irrespective of the presence or absence of a bleeding tendency, had abnormal capillary fragility. This persisted with little change for at least four or five months after the onset of the disease. These observations suggest that the hemorrhages were, at least in part, of vascular origin, since abnormal capillary fragility was the only regularly occurring defect in the hemostatic mechanism. The slow subsidence of the observed changes favors a neurogenic causation. An interplay may be considered between the reduced capillary resistance and one or more unknown factors, possibly resulting from the unphysiological state of many patients during the acute phase of the disease. The results of experiments in animals carried out by other workers suggest that the poliomyelitis infection may be associated with the occurrence of autoantibodies, possibly caused by the destruction of tissue resulting from the infection, which may have a harmful effect on the capillary wall.

PEDIATRICS

Congenital Nonhemolytic Jaundice with Disease of the Central Nervous System. I. M. Rosenthal, H. J. Zimmerman and N. Hardy. Pediatrics 18:378-386 (Sept.) 1956 [Springfield, Ill.].

The authors describe a case of persistent severe jaundice and progressive neurological disease in a 5-year-old boy. The neurological symptoms did not appear until he was 3 years old, although the jaundice was first noted when he was 2 days old. The condition was either the same as or closely related to the "congenital nonhemolytic jaundice with kernicterus," recently described by Crigler and Najjar in eight members of a single large family, although the patient was not a blood relative of this family. The jaundice observed in this condition is the result of the reduced capacity of the liver cells to metabolize and excrete bilirubin, but the pathophysiological mechanism remains obscure. The neurological syndrome consisted of staggering gait, slow and scanning speech, and an intention tremor. An electroencephalogram revealed irregular high voltage, 5 to 8 per second activity with some 3 to 5 per second activity in all areas. Atypical irregular sleep frequencies with a few suggestive discharges were present in the temporal areas. The neurological syndrome is believed to be the result of bilirubin encephalopathy. The authors prefer to use this term to signify damage to the central nervous system resulting from the toxic effects of bilirubin on the brain, and they believe the term "kernicterus" should be restricted to the pathological findings of pigmentation of the basal nuclei.

At laparotomy the patient's liver and gallbladder appeared normal, and the extrahepatic biliary system was patent. Biopsy of the liver was performed, and sections showed that the parenchymal cells were essentially normal. There was some vacuolization of many nuclei. No bile pigment was detected within the cells. In the portal areas, around the central veins, and occasionally between the liver cords were small foci of inflammatory cells. The patient made a good recovery from the operation. He has become able to walk a short distance unaided, but with a markedly ataxic gait. However, he is no longer able to feed himself. The course of this patient indicates that development of bilirubin encephalopathy is not necessarily confined to infancy. It can, apparently, occur in young children, and probably in older children and adults, if the concentrations of indirect-reacting bilirubin in the serum are sufficiently high for a prolonged period.

Transient Dysproteinemia in Infants, a New Syndrome: I. Clinical Studies. R. A. Ulstrom, N. J. Smith and E. M. Heimlich. A. M. A. J. Dis. Child. 92:219-253 (Sept.) 1956 [Chicago].

Four infants under 8 months of age with an unusual syndrome of edema, irritability, and pallor were studied during an 18-month period. All four were born at term, had had an optimal diet, and had no laboratory evidence of renal or hepatic disease. Marked hypoproteinemia was present in each patient at some time during the illness. The age of onset of symptoms ranged from less than 1 month to 7 months. The disease was apparently self-limited, with spontaneous recovery occurring in each infant between the 7th and 9th months of life. The striking similarity of the clinical findings in these patients suggests a single disease process. The extensive studies reported here seem to indicate that an abnormality in protein metabolism at the cellular level is responsible. The normal dietary intakes during the development of anemia and hypoproteinemia and the spontaneous return to normal without recognizable changes in the diet, as well as the many studies presented here, indicate that this disturbance was not primarily of dietary origin. The evidence at hand does not permit assignment of a definite etiological factor, although the mechanism for the development of signs and symptoms seems clear.

DERMATOLOGY

Malignant Blue Nevus. E. R. Fisher. A.M.A. Arch. Dermat. 74:227-231 (Sept.) 1956 [Chicago].

A 27-year-old white man first noticed a pinhead-sized blue nodule in the right occipital region of the scalp at the age of 17. Four years later he noted a progressive enlargement of the lesion and a mass in the right cervical region. Biopsy of the latter revealed a secondary malignant melanoma within a lymph node. The pigmented lesion of the scalp was excised, and a radical dissection of the right cervical lymph nodes was performed. The patient remained in good health during the next six years, but three months before hospitalization he noted a 20-lb. weight loss and numerous pigmented and nonpigmented nodules on the skin of the neck, back, and abdomen. There was weakness, anorexia, and moderately severe pain in the right upper abdominal quadrant. Examination revealed the liver to be enlarged and nodular. In addition to the cutaneous nodules, which varied in size from several millimeters to 1 cm. in cross diameter, several lymph nodes in the posterior cervical chain on the right were also palpably enlarged.

A needle biopsy of the liver was performed, and one of the subcutaneous nodules was excised. The clinical and morphological features of the malignant melanoma removed from this patient's scalp indicate its origin from a blue nevus. The vacuolation of the tumor cells, carcinomatous configuration, and nuclear pleomorphism and occasional mitotic figures are considered diagnostic of malignancy in lesions presenting other features of the blue nevus. It is interesting to note that the morphological appearance of the metastatic lesions in the subcutaneous tissue and liver did not possess features that would enable one to establish their derivation from the blue nevus. The tumor cells were spindle-shaped, without vacuolation, and resembled other malignant melanomas not arising in blue nevus. The vacuolation of the tumor cells observed is not unlike the change noted in the tumor cells of some melanomas during pregnancy. Such cytological alteration suggests a hormonal influence upon the tumor cells of this lesion, although this patient did not reveal any overt clinical manifestations of endocrine imbalance. The significance and nature of the asteroid bodies observed within the cytoplasm of some of the tumor cells of the present malignant blue nevus are not apparent. As far as the author was able to ascertain, such structures have not previously been recorded in pigmented tumors of the nevus-melanoma type.

Necrobiosis Lipoidica: A Disease of Changing Concepts. J. Graham Smith Jr. A.M.A. Arch. Dermat. 74:280-285 (Sept.) 1956 [Chicago].

The author analyzed the records of 19 patients with necrobiosis lipoidica seen at Duke Hospital. Data obtained on these 19 patients were compared with tabulated data from 34 of a total of 52 cases of necrobiosis lipoidica reported in the A.M.A. *Archives of Dermatology and Syphilology* during the past 10 years. Regarding the 19 cases, he says that in only one-fourth of these was necrobiosis lipoidica associated with diabetes mellitus even when patients with equivocal but not definitely diabetic glucose-tolerance curves were included in the diabetic group. When diabetes mellitus is associated with necrobiosis lipoidica, the diabetes mellitus usually develops first; however, the association of diabetes mellitus apparently does not alter significantly the age of onset for necrobiosis lipoidica. In reviewing the slides from 13 of the 19 patients, it was found that in only 4 of the 13 did there seem to be a resemblance to granuloma annulare, and so the author concludes that necrobiosis is probably not a variant of granuloma annulare.

Approximately 90% of cases of necrobiosis lipoidica occur in women; the Negro and Oriental races are rarely affected if at all, and the disease, while more commonly having its onset in young adults, occurs in all age groups except in infancy and early childhood. Lesions are not frequently seen in locations other than the lower extremities. Ulceration probably occurs more frequently in diabetics, but it may occur in nondiabetics. Mucous membrane lesions do not occur. The etiology of necrobiosis lipoidica is obscure, but the pathological changes are probably secondary to vascular abnormalities. Surgical excision with grafting if necessary to close large defects is the most effective therapy available at present. Intralesional injection of hydrocortisone deserves further trial.

Nickel Dermatitis. H. T. H. Wilson. Practitioner 177:303-308 (Sept.) 1956 [London, England].

This report is concerned with dermatitis resulting from contact with nickel or nickel-plated articles. Nickel-plated articles, such as the metallic parts of garters, are nearly always barrel plated: that is to say, they are nickel plated in an acid nickel solution in a rotating barrel. The thickness of nickel deposited is usually of the order of 0.0002 in. (0.05 mm.). When the plating process is complete, the articles are washed in hot water. Unless the washing is adequate, the plated articles are likely to become coated with a thin film of nickel salts. This may account for the fact that dermatitis often seems to develop for the first time soon after the wearing of a comparatively new nickel-plated buckle or clasp. In the present series of 85 women, 12 out of 22 stated that their dermatitis arose beneath a nickel-plated article purchased a month or less previously. The rash began as a localized dermatitis, usually at the back of the thighs, at the point of contact with the garter buckles. Less frequently it began under a wrist watch, necklace clasp, or earring. Swelling and redness of the eyelids sometimes preceded all other symptoms, and occasionally a chronic papular eruption developed on the elbow flexures or axillary folds before the onset of lesions elsewhere. In only two patients did the rash remain localized to a single area. In the remainder, after a few weeks or months, eczematous patches developed on other parts of the body. Nickel dermatitis appears to consist of two separate components: a simple dermatitis localized to the area of nickel contact, and a chronic eczema or neurodermatitis having no obvious connection with such contact. These two components are so intimately associated that the diagnosis of suspender dermatitis can often be made on seeing the characteristic papular rash on the patient's elbow flexures.

All patients were patch-tested against metallic nickel and solutions of nickel sulfate. In every case strongly positive reactions were observed to nickel sulfate (2.5%), and severe reactions followed the few tests made with higher concentrations. It would appear from serial tests that a 1% solution is a suitable strength for patch testing and solutions stronger than 2.5% should not be used. Metallic nickel gave a reaction equal to 0.5 or 1% of the solution. Complete removal of all metal clasps and buckles did not suffice to prevent relapses in every case. Nickel sensitivity, once acquired, is likely to persist.

INDUSTRIAL MEDICINE

Silage Gas Poisoning: Nitrogen Dioxide Pneumonia, a New Disease in Agricultural Workers. R. R. Grayson. Ann. Int. Med. 45:393-408 (Sept.) 1956 [Lancaster, Pa.].

Two patients with acute respiratory disease due to inhalation of silage gas were observed by the author in August, 1954. One died. A thorough investigation of these two cases and of the silage gas that caused the illness indicates that the disease was caused by the oxides of nitrogen and is essentially a diffuse chemical bronchopneumonia caused by the irritating action of nitrous and nitric acids on the respiratory tree. The disease may be mild or severe, depending upon the degree of exposure. Nitrogen dioxide pneumonia has been described many times in industrial toxicology but has apparently not been previously described in the medical literature as due to inhalation of gases from ensilage. Special studies carried out on the corn ensilage and on the actual gas from the silo in which the two patients were poisoned proved that there was a poisonous concentration of the oxides of nitrogen. This condition was due to a combination of drought, high-nitrate soils, and an unventilated silo. Other studies demonstrated the toxicity of the actual gas and of experimentally produced gas from the same ensilage. Silage gas poisoning due to the oxides of nitrogen with the production of chemical pneumonia is a disease that probably occurs more commonly than is recognized. Physicians in rural areas should be aware of the possibility of this disease during summer periods when corn is being placed in silos, particularly during times of drought. No specific treatment is known for the resulting bronchopneumonia. Research should be directed toward the discovery of a specific therapy.

PATHOLOGY

Cushing's Syndrome in Children Associated with Adrenal Cortical Carcinoma: A Case Report with Review of the Literature. G. H. Guin and E. F. Gilbert. A. M. A. J. Dis. Child. 92:297-307 (Sept.) 1956 [Chicago].

A 3-month-old girl was admitted to the Children's Hospital of the District of Columbia because of obesity beginning 6 weeks before admission. For three weeks before admission the patient was noted to have an eczematoid and acne-form rash on the cheeks. The infant was obese, showing a buffalo hump and moon face. There was no axillary or pubic hair and no abnormality of the external genitalia other than slight clitoral hypertrophy. There was hirsutism of the upper lip and an erythematous papular rash over the face and neck. The abdomen was distended, and the liver was palpable. A firm mass unattached to the liver was palpated to the right of the umbilicus. X-ray examination revealed marked osteoporosis of the entire skeletal system. Exploratory laparotomy revealed a tumor replacing the right adrenal, which was removed. The infant died on the fourth postoperative day after several episodes of apnea. Examination of the surgical specimen established the diagnosis of cortical carcinoma of the right adrenal.

Twenty-eight cases of adrenal cortical carcinoma associated with Cushing's syndrome in children under 14 years of age were collected from the literature. The reported case is believed to concern the youngest patient with adrenal cortical carcinoma on record. The fact that the mother of this infant had diabetes is considered to be of special interest. Of the 29 tabulated cases, 20 occurred in females and 9 in males. Eighteen patients died, and all but one of these came to autopsy. Histological confirmation of adrenal cortical carcinoma in this patient had been obtained surgically. Nine patients underwent surgical treatment. Persistent elevations of plasma and urinary 17-hydroxycorticosteroids and urinary 17-ketosteroids after ACTH stimulation provide an additional aid for the diagnosis of adrenocortical carcinoma.

THERAPEUTICS

Hydergine (a Vasodilator): Clinical Report on Hydergine in Peripheral Vascular Disease. W. deHaven Stick. Pennsylvania M. J. 59:1072-1074 (Sept.) 1956 [Harrisburg, Pa.].

Having found that vasodilating agents such as tetraethylammonium chloride, Priscoline, and Ilidar phosphate were inadequate in the treatment of functional or organic occlusive vascular disease of the lower extremities, the author tried hydergine, an equiproportional mixture of the three hydrogenated alkaloids of the "ergotoxine group," namely, ergocristine, ergocornine, and ergokryptine. Nearly 2000 oral and 200 parenteral doses of hydergine have been given in the course of the last six months to about 20 patients at the New York Hospital. The majority of these patients with arteriosclerotic obstructive vascular disease were in the 55 to 75 year age group. Pallor, atrophy, reduced temperature, cyanosis, intermittent claudication, early digital necrosis, nocturnal ischemia, and frank gangrene of one or more digits were the characteristic symptoms. The drug was also given to a few patients with functional obstruction as seen in association with thrombophlebitis, phlebothrombosis, hyperhidrosis, and, in one patient, frostbite residuum. All routes of drug administration were utilized in nearly every patient, including the oral, sublingual, parenteral, and direct intra-arterial routes. The drug was given to each patient for at least six days.

Only five patients obtained palliative benefit from treatment with hydergine, and only one patient showed actual progress in healing. Hydergine with Ilidar may be indicated in acutely painful ischemia of the lower limbs as a preliminary or adjunct to surgical treatment. Hydergine, given intravenously, appears to be a drug of choice in coping with acute hypertensive phenomena precipitated by the injection of radiographic substances for diagnostic procedures. Medical sympathectomy by the use of vasodilating agents, including hydergine, is of slight value in the management of peripheral vascular disease. Surgical sympathectomy remains the method of choice when warranted.

The Combination of Reserpine with Methyl-Phenyl-Piperidine Acetate in the Treatment of Hypertension. G. Visco. Clin. terap. 11:11-32 (July) 1956 (In Italian) [Rome, Italy].

Reserpine has several side-effects and is ineffective in many types of hypertension. Methyl-phenyl-piperidine acetate (A. M. F. P.) has a central sympathomimetic stimulant effect and a mild sympathicoperipheral effect. A combination of the two drugs was used in the treatment of 23 patients with hypertension who were followed for from 1 to 14 months after the treatment. They were between 18 and 73 years of age (average age, 49.8 years). Eighteen patients had essential hypertension, 3 had malignant hypertension, and 2 had chronic nephritis in a preuremic state. Ten patients (43.4%) showed a great reduction in the pressure values. The decrease in the systolic pressure was marked; the decrease in the diastolic pressure was less marked but more constant. A. M. F. P. did not interfere with the hypotensive effect of reserpine, but did prevent its side-effects: drowsiness, asthenia, psychic torpor, and vertigo. Bradycardia, nasal congestion, and hypothermia were also somewhat checked with the use of A. M. F. P. The collateral effects, such as the increase in the appetite and body weight, were less marked but still very significant. The two drugs had a synergistic effect on the patients' euphoria and the incidence of tremor, diarrhea, and night dreams.

In another experiment the authors gave a dose of 15 mg. per day of A. M. F. P. to 13 patients who were being treated with high doses of reserpine. The effects of A. M. F. P. on side-effects were less evident: 10 of the 13 patients had bradycardia, 9 had asthenia and mental torpor, and 7 had nasal stuffiness. Treatment had to be discontinued in 4 patients who were receiving the drug by intramuscular injection.

Severe Hypoglycemic Reactions in the Course of Treatment of Diabetes Mellitus with Carbutamide (BZ-55). E. Bendfeldt and H. Otto. München. med. Wchnschr. 98:1136-1137 (Aug. 31) 1956 (In German) [Munich, Germany].

Severe hypoglycemic reactions to carbutamide (BZ-55) occurred in 2 of 740 patients with diabetes mellitus who were treated with this drug. The patients were adipose women aged 59 and 70 years who were given 5 tablets of the drug on the first day of the treatment, 4 tablets on the second day, 3 tablets on the third day, and 2 tablets on successive days. In the younger patient, who had hypertension, cardiac decompensation, and diabetic nephropathy and who had been treated with insulin for many years, the fasting blood sugar level varied between 230 and 310 mg. per 100 cc. before the institution of carbutamide therapy; it dropped to 105 mg. per 100 cc. on the 10th day of treatment, when drowsiness and a mild right facial paresis occurred. In the evening of the same day the patient became unconscious and the blood sugar level dropped to 35 mg. per 100 cc. The patient became conscious within a few minutes after the intravenous administration of 40 gm. of dextrose, (in 50% solution), and the neurological symptoms disappeared completely. Despite the administration of carbohydrates, the blood sugar level still bordered on hypoglycemia 27 hours after the last carbutamide tablet had been given. In the older patient, who had severe general atherosclerosis and who had been admitted to hospital for sclerotic gangrene in the right foot, the presence of diabetes mellitus had not previously been recognized, but the blood sugar level on admission was found to vary between 177 and 242 mg. per 100 cc. On the third day of carbutamide therapy the fasting blood sugar level had dropped to 90 mg. per 100 cc., when the patient became drowsy, confused, and finally unconscious with rattling breathing. An apoplectic attack was considered and the patient was given aminophylline and 10 gm. of dextrose, and after that her responsiveness was somewhat improved. The diagnosis of a hypoglycemic reaction was established by the determination of a blood sugar level of 70 mg. per 100 cc. Consciousness was restored completely after the intravenous administration of an additional 25 gm. of dextrose, but five hours later she again became unconscious. Consciousness was restored once more by the intravenous administration of 25 gm. of dextrose, and after that she was given 15 gm. dextrose orally every hour.

In these two patients, the insidious and protracted course of the condition and the central nervous manifestations, which dominated the clinical picture and which subsided within a short time after the intravenous administration of dextrose, reminded one of hypoglycemic shock after the administration of long-acting insulin. Both patients had other diseases in addition to diabetes. Preuremia with residual nitrogen values of 60 mg. per 100 cc. was present at the onset of hypoglycemia in both patients. Determinations of carbutamide in the blood and urine of the older of the two patients showed that the carbutamide blood concentration was within the usual limits 24 hours after the onset of hypoglycemia and that the carbutamide excretion in the urine was not reduced as compared with that in patients without renal impairment who had received the same dose of the drug. These findings suggest that at least in this patient renal impairment did not inhibit the excretion of carbutamide in the urine and, therefore, did not cause an accumulation of the drug in the blood that could have been responsible for the hypoglycemia. Patients with diabetes of long duration associated with severe late complications, as in the younger woman, may have a tendency to pronounced variations in their blood sugar level, and hypoglycemia may result from insignificant causes.

RADIOLOGY

Carcinoma of the Lip. P. M. Burke and F. S. Hopkins. New England J. Med. 255:552-555 (Sept. 20) 1956 [Boston].

During the 12-year period from 1938 through 1950, 225 patients with cancer of the lip were seen in the cancer section of the Westfield State Sanatorium. This report is based on an analysis of the 182 patients who received their primary treatment at this institution. All lesions were histologically proved squamous-cell carcinoma, and all patients have been followed for over five years. All except 6 of the 182 patients were men. Treatment consisted of surgical removal of the tumor in 69 patients, while 97 patients received only irradiation treatment and 16 received a combination of surgical and x-ray therapy. One hundred eighteen (65%) of the 182 patients survived for five years without recurrence. The five-year survival rate is 80% when it is adjusted for the 35 patients who died within five years of other causes without recurrence of cancer. This compares well with the five-year cure rate reported by others. There is considerable difference of opinion in the literature about the best method of treating the primary lesion. Surgical therapy is favored by some and irradiation by others. The authors found that primary lip cancers comparable in size and histological grade respond about as well to x-ray as to surgical therapy. When an enlarged lymph node is present, the extent of the neck dissection should be decided on an individual basis. Routine neck dissection for cancer of the lip without enlarged lymph nodes is not recommended.

Primary Chickenpox Pneumonia. D. Y. M. Tan, S. A. Kaufman and G. Levene. Am. J. Roentgenol. 76:527-532 (Sept.) 1956 [Springfield, Ill.].

It is not generally realized that the varicella virus is capable of producing such complications as pneumonia, encephalitis, and nephritis. Only 15 well-documented cases (including four fatal ones) of chickenpox pneumonia have appeared in the literature up to 1955. The authors present observations on 16 patients seen at the John Haynes Memorial of the Massachusetts Memorial Hospitals. Pneumonia as a complication of chickenpox occurred in adults over the age of 19 with one exception, a 5-year-old girl. The onset of the respiratory symptoms occurred within five days of the appearance of the rash. The rash was severe, and in most patients confluent over the whole body. Vesicles were also found in the mouth and pharynx. The patients were acutely ill, with temperatures of from 101 to 105 F (38 to 41 C). They had severe cough and several had hemoptysis. Half of them had chest pain and dyspnea. Physical examination of the chest was generally not remarkable despite the extensive roentgen changes. Three patients had generalized lymph-node enlargement. The white blood cell count was elevated in slightly less than half of the cases, but the differential count remained normal in all.

The roentgenologic changes showed a characteristic pattern. There were widespread nodular densities superimposed on increased bronchovascular markings. These infiltrates varied in size, and though some were sharply defined from the surrounding lung others seemed to merge with the adjacent tissue. Transitory changes were common, and the disease, in some cases, changed rapidly, some areas of infiltration resolving while others appeared. In a few instances there was a tendency for the nodules to coalesce so that there appeared to be patchy areas of consolidation. This was most noticeable ot the lung bases. No portion of the lung was spared, although the densities seemed heaviest about the hilum and gradually diminished toward the periphery. While an etiological diagnosis of pneumonia is not possible from the roentgenologic examination alone, it has been the experience of these authors that these striking findings in a patient with chickenpox can be taken as presumptive evidence of primary varicella pneumonia. This can usually be confirmed by clinical and laboratory findings. Various chemotherapeutic agents were tried without success, the disease varying in duration from a few days to two weeks. There were no fatalities.

Therapy of Dupuytren's Contracture. K. Wasserburger. Strahlentherapie 100:546-560 (No. 4) 1956 (In German) [Munich, Germany].

At the department for irradiation therapy of a Vienna Hospital efforts have been made to develop an effective radium therapy for Dupuytren's contracture. Radium therapy is carried out with an apparatus for distant therapy, which is a circular arrangement of eight barrel-shaped holders, each of which contains 50 mg. radium element. The 400 mg. of radium element are filtered through 1 mm. of platinum. Lateral shielding is provided by 4 cm. of lead. The instrument is mounted in such a way that the effective cone of rays can be directed and fixed in any desired position. The radium-skin distance in the treatment of Dupuytren's contracture was 2 cm. The size of the field of treatment was 5 sq. cm. Depending on the extent of the lesion and on whether one or several fingers was involved from three to five fields were irradiated on each hand. If necessary the series of treatments was repeated after from three to six months.

Irradiation treatment was applied to 213 patients with Dupuytren's contracture during the years from 1937 to 195 The irradiation was the primary treatment in 185 of thes patients, the remaining 28 having first received surgical treatment. Follow-up studies on 146 of the 185 patients revealed that in 102 the results were very good, 24 others obtained improvement, and the remaining 20 experienced no improvement.

In classifying the lesions according to the degree of severity and advancement, it was found that of the patients with stage 1 lesions, 89.8% were cured; of those with stage 2 lesions, 56.5%; and of those with stage 3 lesions, 32.2%. This indicates the importance of early treatment.

Angiocardiography in the Preoperative Diagnosis of Mitral Stenosis and Insufficiency. J. G. McAfee, T. F. Hilbish and K. R. Stewart. Radiology 67:321-331 (Sept.) 1956 [Syracuse, N. Y.].

The authors performed angiocardiography in 50 patients with mitral rheumatic heart disease, but this report is concerned only with the 32 surgically proved cases. Although the surgical correction of mitral stenosis has become firmly established, that of mitral regurgitation has remained largely experimental. In the preoperative evaluation of patients, therefore, the accurate differentiation of stenosis from insufficiency is of the utmost importance. Angiocardiography is not a reliable procedure for distinguishing between mitral stenosis and insufficiency. The diagnostic accuracy was poorer than that of conventional clinical methods. Both false-positive and false-negative diagnoses of mitral stenosis were made. In this, as in other unselected series, patients with stenosis predominated. The problem of selecting the small minority with predominant insufficiency has not been solved by angiocardiography. No difference in the "opacification pattern" of the left atrium and ventricle was observed in stenosis and insufficiency that could not be explained on the basis of chamber size and cardiac phase. The prolonged opacification of the left atrium seen in mitral disease is due to its large size and generalized slowing of the circulation. In the absence of shunts, the output (volume per unit time) in all chambers of the heart remains equal; there is no specific "hold-up" of the contrast medium in the left atrium by a stenotic mitral valve. Angiocardiography is of value in demonstrating the size and position of the cardiac chambers, but this can usually be assessed by ordinary roentgenographic means. Left ventricular enlargement was demonstrated in only two of five patients with proved "pure" mitral insufficiency. It may be possible in the future to visualize the mitral valve orifice by selective angiocardiography performed through a direct left atrial puncture.

Congenital Cystic Adenomatoid Malformation of the Lung in Infants. J. M. Craig, J. Kirkpatrick and E. B. D. Neuhauser. Am. J. Roentgenol. 76:516-526 (Sept.) 1956 [Springfield, Ill.].

Formation of cysts related to alveolar and interstitial emphysema is frequent in early life in infants suffering from neonatal asphyxia associated with the formation of hyaline membranes and in those with pneumonia, due to Streptococcus pyogenes. Cysts of this origin usually resorb quickly and without sequelae. Infants with indisputably congenital cystic malformations have been observed at the Children's Medical Center of Harvard University over the past 25 years, in whom the structure of the cystic lungs was such that it was inconceivable that they would ever function normally or that the cysts would disappear spontaneously. In the four cases reported, surgical extirpation was carried out in the first two weeks of life. They presented the identical features described by Ch'in and Tang as "congenital adenomatoid malformation." All four infants had similar signs and symptoms, consisting of cyanosis, rapid respirations, and an absence of respiratory distress or fever. The physical signs were those of displacement of the mediastinum to the side opposite that of the affected lung, dulness to percussion over the affected lung, and diminished breath sounds over this area. The roentgen signs in all four infants were those of an intrapulmonary mass of soft-tissue density, containing scattered radiolucent areas. The outlines of the mass were usually quite sharp and the malformation was limited to one lobe. A roentgenogram taken very early in life may show only the presence of a soft-tissue density without any radiolucent air-containing areas, at a time before any air has penetrated the honeycombed mass. At operation, the mass was usually well defined. The anatomy of the lesion is striking because of the great increase in size and weight of the affected portion, many of the affected lungs being twice the usual dimensions and weight.

Since in two of the infants the involved lungs increased rapidly in size with a concomitant increase in the air-containing cystic structures with further displacement of the mediastinum and compromise of respiratory function, it appears that once a definite diagnosis of such adenomatoid cystic malformations is made, surgical treatment is mandatory. It proved effective in three of the four infants, but the fourth infant died two days after the operation. Congenital cystic adenomatoid malformation should not be confused with either the accessory lung, which has no connection with the bronchial system or pulmonary blood supply, or with the sequestrated lobe, which is usually connected with the bronchial system but derives its blood supply from a branch of the aorta.

PHYSIOLOGY

A Comparison of the Biological Values of Dietary Protein Incorporated in High- and Low-Fat Diets. V. C. Metta and H. H. Mitchell. J. Nutrition 59:501-513 (Aug.) 1956 [Philadelphia].

The effect of fat as compared with that of isocaloric amounts of carbohydrate on nitrogen utilization in the severely protein-depleated and the growing rat was investigated. The low-fat and the high-fat diets contained, respectively, 5 and 33% fat, mainly lard. Casein was the dietary protein tested. The rats were fed the test diets so that they received equal amounts of protein, crude fiber, vitamins, minerals, and gross energy, the main difference between the two groups being in the fat intake. When fed in isocaloric amounts, dietary fat and carbohydrate had essentially the same effect on protein utilization in both the protein-depleted rat and the growing rat. Neither the apparent digestibility nor the true digestibility of casein was improved by the higher dietary fat level. Fat did not seem to spare endogenous nitrogen under conditions of satisfactory and equal caloric intake. Higher dietary fat levels did not improve the biological value of casein. In fact, the indications in one experiment were that a high-carbohydrate diet tends to improve the biological value of casein in the protein-depleted rat. The metabolic fecal nitrogen per gram of food intake increased significantly when the dietary fat was increased because of a concomitant reduction in the food intake due to isocaloric feeding. This value, however, remained constant irrespective of the fat content of the diet when the rats were fed equal amounts of the low-fat and the high-fat diets.

The Determination of Chromosomal Sex by Oral Smears. W. Herrmann and A. M. Davis. Yale J. Biol. & Med. 29:69-74 (Sept.) 1956 [New Haven, Conn.].

Oral smears were obtained from 100 persons of varying ages for a control series. Fifty men and 50 women each had the buccal mucosa scraped with a wooden spatula. The material obtained was smeared on a glass slide and immediately dropped into a solution containing equal parts of ether and 95% ethyl alcohol. The slides were then stained with the Papanicolaou stain. Each slide was studied under an oil immersion lens, and the sex chromatin was easily identified. The sex of the person from whom the specimen was obtained was not known until after the counts had been made.

The authors then applied the test to 15 patients whose true sex was questionable. Four of these patients had been given a clinical diagnosis of pseudohermaphroditism, three being considered anatomically female and one anatomically male. One of the three females had proved congenital adrenal hyperplasia, with a diagnosis confirmed by the elevated beta fraction of the 17-ketosteroids. The other two were newborn twins on whom no endocrine essays had as yet been performed. These twins showed a phallus-like development of the clitoris. All three patients had a female chromosomal pattern. The anatomically male pseudohermaphrodite was 44 years old and had previously been given a diagnosis of a male achondroplastic dwarf. A chromatin count indicated that this patient was genetically female. Two of the patients with gonadal dysgenesis proved to be chromosomally male, even though they had female genitalia and were living satisfactory lives emotionally, physically, and mentally as females. The true hermaphrodite had female external genitalia, a testis on one side and an ovary on the other, and a chromatin count following a female pattern. In the remaining cases the chromosomal sex corresponded with the anatomic sex.

day of the treatment, 4 tablets on the second day, 3 tablets on the third day, and 2 tablets on successive days. In the younger patient, who had hypertension, cardiac decompensation, and diabetic nephropathy and who had been treated with insulin for many years, the fasting blood sugar level varied between 230 and 310 mg. per 100 cc. before the institution of carbutamide therapy; it dropped to 105 mg. per 100 cc. on the 10th day of treatment, when drowsiness and a mild right facial paresis occurred. In the evening of the same day the patient became unconscious and the blood sugar level dropped to 35 mg. per 100 cc. The patient became conscious within a few minutes after the intravenous administration of 40 gm. of dextrose, (in 50% solution), and the neurological symptoms disappeared completely. Despite the administration of carbohydrates, the blood sugar level still bordered on hypoglycemia 27 hours after the last carbutamide tablet had been given. In the older patient, who had severe general atherosclerosis and who had been admitted to hospital for sclerotic gangrene in the right foot, the presence of diabetes mellitus had not previously been recognized, but the blood sugar level on admission was found to vary between 177 and 242 mg. per 100 cc. On the third day of carbutamide therapy the fasting blood sugar level had dropped to 90 mg. per 100 cc., when the patient became drowsy, confused, and finally unconscious with rattling breathing. An apoplectic attack was considered and the patient was given aminophylline and 10 gm. of dextrose, and after that her responsiveness was somewhat improved. The diagnosis of a hypoglycemic reaction was established by the determination of a blood sugar level of 70 mg. per 100 cc. Consciousness was restored completely after the intravenous administration of an additional 25 gm. of dextrose, but five hours later she again became unconscious. Consciousness was restored once more by the intravenous administration of 25 gm. of dextrose, and after that she was given 15 gm. dextrose orally every hour.

In these two patients, the insidious and protracted course of the condition and the central nervous manifestations, which dominated the clinical picture and which subsided within a short time after the intravenous administration of dextrose, reminded one of hypoglycemic shock after the administration of long-acting insulin. Both patients had other diseases in addition to diabetes. Preuremia with residual nitrogen values of 60 mg. per 100 cc. was present at the onset of hypoglycemia in both patients. Determinations of carbutamide in the blood and urine of the older of the two patients showed that the carbutamide blood concentration was within the usual limits 24 hours after the onset of hypoglycemia and that the carbutamide excretion in the urine was not reduced as compared with that in patients without renal impairment who had received the same dose of the drug. These findings suggest that at least in this patient renal impairment did not inhibit the excretion of carbutamide in the urine and, therefore, did not cause an accumulation of the drug in the blood that could have been responsible for the hypoglycemia. Patients with diabetes of long duration associated with severe late complications, as in the younger woman, may have a tendency to pronounced variations in their blood sugar level, and hypoglycemia may result from insignificant causes.

RADIOLOGY

Carcinoma of the Lip. P. M. Burke and F. S. Hopkins. New England J. Med. 255:552-555 (Sept. 20) 1956 [Boston].

During the 12-year period from 1938 through 1950, 225 patients with cancer of the lip were seen in the cancer section of the Westfield State Sanatorium. This report is based on an analysis of the 182 patients who received their primary treatment at this institution. All lesions were histologically proved squamous-cell carcinoma, and all patients have been followed for over five years. All except 6 of the 182 patients were men. Treatment consisted of surgical removal of the tumor in 69 patients, while 97 patients received only irradiation treatment and 16 received a combination of surgical and x-ray therapy. One hundred eighteen (65%) of the 182 patients survived for five years without recurrence. The five-year survival rate is 80% when it is adjusted for the 35 patients who died within five years of other causes without recurrence of cancer. This compares well with the five-year cure rate reported by others. There is considerable difference of opinion in the literature about the best method of treating the primary lesion. Surgical therapy is favored by some and irradiation by others. The authors found that primary lip cancers comparable in size and histological grade respond about as well to x-ray as to surgical therapy. When an enlarged lymph node is present, the extent of the neck dissection should be decided on an individual basis. Routine neck dissection for cancer of the lip without enlarged lymph nodes is not recommended.

Primary Chickenpox Pneumonia. D. Y. M. Tan, S. A. Kaufman and G. Levene. Am. J. Roentgenol. 76:527-532 (Sept.) 1956 [Springfield, Ill.].

It is not generally realized that the varicella virus is capable of producing such complications as pneumonia, encephalitis, and nephritis. Only 15 well-documented cases (including four fatal ones) of chickenpox pneumonia have appeared in the literature up to 1955. The authors present observations on 18 patients seen at the John Haynes Memorial of the Massachusetts Memorial Hospitals. Pneumonia as a complication of chickenpox occurred in adults over the age of 19 with one exception, a 5-year-old girl. The onset of the respiratory symptoms occurred within five days of the appearance of the rash. The rash was severe, and in most patients confluent over the whole body. Vesicles were also found in the mouth and pharynx. The patients were acutely ill, with temperatures of from 101 to 105 F (38 to 41 C). They had severe cough and several had hemoptysis. Half of them had chest pain and dyspnea. Physical examination of the chest was generally not remarkable despite the extensive roentgen changes. Three patients had generalized lymph-node enlargement. The white blood cell count was elevated in slightly less than half of the cases, but the differential count remained normal in all.

The roentgenologic changes showed a characteristic pattern There were widespread nodular densities superimposed on increased bronchovascular markings. These infiltrates varied in size, and though some were sharply defined from the surrounding lung others seemed to merge with the adjacent tissue. Transitory changes were common, and the disease, in some cases, changed rapidly, some areas of infiltration resolving while others appeared. In a few instances there was a tendency for the nodules to coalesce so that there appeared to be patchy areas of consolidation. This was most noticeable at the lung bases No portion of the lung was spared, although the densities seemed heaviest about the hilum and gradually diminished toward the periphery. While an etiological diagnosis of pneumonia is not possible from the roentgenologic examination alone, it has been the experience of these authors that these striking findings in a patient with chickenpox can be taken as presumptive evidence of primary varicella pneumonia. This can usually be confirmed by clinical and laboratory findings. Various chemotherapeutic agents were tried without success, the disease varying in duration from a few days to two weeks. There were no fatalities.

Therapy of Dupuytren's Contracture. K. Wasserburger. Strahlentherapie 100:546-560 (No. 4) 1956 (In German) [Munich, Germany].

At the department for irradiation therapy of a Vienna Hospital efforts have been made to develop an effective radium therapy for Dupuytren's contracture. Radium therapy is carried out with an apparatus for distant therapy, which is a circular arrangement of eight barrel-shaped holders, each of which contains 50 mg. radium element. The 400 mg. of radium element are filtered through 1 mm. of platinum. Lateral shielding is provided by 4 cm. of lead. The instrument is mounted in such a way that the effective cone of rays can be directed and fixed in any desired position. The radium-skin distance in the treatment of Dupuytren's contracture was 2 cm. The size of the field of treatment was 5 sq. cm. Depending on the extent of the lesion and on whether one or several fingers was involved from three to five fields were irradiated on each hand. If necessary the series of treatments was repeated after from three to six months.

Irradiation treatment was applied to 213 patients with Dupuytren's contracture during the years from 1937 to 1953 The irradiation was the primary treatment in 185 of these patients, the remaining 28 having first received surgical treatment. Follow-up studies on 146 of the 185 patients revealed that in 102 the results were very good, 24 others obtained improvement, and the remaining 20 experienced no improvement.

Handbook of Legal Medicine. By Louis J. Regan, M.D., LL.B., Professor of Legal Medicine, University of Southern California, Los Angeles, and Alan R. Moritz, M.D., Professor of Pathology, Western Reserve University, Cleveland. Cloth. $3.90. Pp. 201, with 11 illustrations. C. V. Mosby Company, 3207 Washington Blvd., St. Louis 3, 1956.

For many years the need in our medicolegal library for a short, simple, concise review of the many subjects referred to under the heading of medical jurisprudence and the various aspects of scientific medicolegal investigations has been recognized. In this book two of the outstanding experts in the United States have discussed these subjects in an understandable and acceptable form to medical and legal students. Unfortunately the average student of law or of medicine has had little or no opportunity to study these subjects during his regular academic schedule. When in the past the need arose or the desire existed to study in this field, the student has been discouraged by the voluminous and technical nature of published material. This obstacle has now been removed. The book will also provide a useful working manual for practicing lawyers and physicians. While it is true that for the few who are expert in these two fields the material presented will be elementary, for most lawyers and physicians, it will be a valuable and useful guide.

Dr. Regan tends to dicuss many subjects in terms of medical professional liability rather than in relation to the broader field of personal injury litigation. Although this approach may mislead some readers as to the importance or significance of some of the subject matter, it has not apparently resulted in any inaccuracies or misstatements. The second portion of the book should be of great value to students and physicians, but it should be particularly helpful to attorneys who are confronted with the investigation, prosecution, or defense of cases involving violent crimes or disputed paternity. This section of the book should provide them with a clear and authoritative commentary on the major aspects of these subjects. The book includes an extensive glossary of medical and legal terms, a detailed table of contents, and a bibliography of selected references in the medicolegal field. This book should be widely circulated not only for the education and edification of students, lawyers, and physicians but also as an important aid in the better administration of justice in civil and criminal cases.

Head Injuries and Their Management. By Francis Asbury Echlin, M.D., C.M., M.Sc., Professor Clinical Neurosurgery, New York University, Postgraduate Medical School, New York. This material was published in American Practitioner and Digest of Treatment for May, 1956. Cloth. $3. Pp. 127, with 10 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; 2083 Guy St., Montreal, Canada; Pitman Medical Publishing Company, Ltd., Pitman House, 39-41 Parker St., Kingsway, London, W.C.2, England, 1956.

The book, which is small enough to slip into a coat pocket, is a brief description of the essentials in diagnosis and treatment of head injuries for residents and the practicing surgeon and physician. There are succinct chapters on the mechanisms of head injury, nonsurgical lesions of the brain, surgical conditions such as hematomas, scalp wounds, skull fractures, penetrating wounds of the brain, and a few paragraphs on infections and other complications, including post-traumatic epilepsy, cerebral palsy, the post-traumatic syndrome of headache, "dizziness" and nervousness, and neuroses, psychoses, and rehabilitation. Discussions of pneumography, angiography, and electroencephalography are so brief as to be of no particular value. A good selective bibliography and an adequate index conclude the volume. Within its limited aims, the volume contains no serious errors except those of omission. Precisely, it is a primer, of limited value for students, interns, and residents. There is nothing here for neurologists or neurosurgeons and nothing to equip a general surgeon for the surgical management of head injuries. It rightly points out that over 97% of closed head injuries require no operation and presents admirably the generally accepted criteria for diagnostic appraisal, observation, and management. As any primer must, it lacks important surgical details, and, even for so brief a manual, it is inadequate in its discussion of all the nonsurgical aspects of head injuries such as the post-traumatic syndrome, pneumography, angiography, and the electroencephalogram. No account is given of the medical treatment of post-traumatic convulsive states. Discussion of the post-traumatic neuroses and psychoses is passed over entirely. The book is thus grossly inadequate; perhaps any brief presentation of the problems of head injuries must be inadequate. To make the complex simple is a most dubious enterprise, as this book amply demonstrates.

Industrial Medicine and Hygiene. Volumes I-III. Edited by E. R. A. Merewether, C.B.E., O.St.J., M.D., H.M. Senior Medical Inspector of Factories, Ministry of Labour and National Service, [London, England.] With foreword by The Lord Horder, G.C.V.O., M.D., F.R.C.P. Cloth. Pp. 426, with 33 illustrations; 451, with 81 illustrations; 617, with 57 illustrations. F. A. Davis Company, 1914-1916 Cherry St., Philadelphia 3; Butterworth & Co., Ltd., 88 Kingsway, London, W.C.2, England; 1367 Danforth Ave., Toronto 6, Canada, 1954; 1956.

This is an ambitious work, as indicated by its title. It comprises three volumes, lists about 1,500 references to the pertinent European and American literature, and contains sections from over 30 contributors representing medicine, pharmacology, toxicology, chemistry, psychology, nursing, industrial hygiene, civil and electrical engineering, law, and management. Besides industrial medical directors and governmental plant inspectors, the physicians contributing include public health specialists, internists, ophthalmologists, otolaryngologists, dermatologists, and some who are lawyers as well. The first volume should be of particular value to the British reader, inasmuch as it presents the background and basis, in British history and law, of workmen's compensation and of programs of industrial health and rehabilitation and the organization and statistics of health services of various British industries. The American reader will derive greater profit from a study of the other two volumes. Volume II deals with occupational skin diseases, ophthalmology, psychology, compressed air, heating, ventilation, lighting, noise, ionizing radiation, and industrial accidents. It discusses the causes, prevention, and in some instances the treatment of harmful effects from these agents and influences. Volume III, far thicker than either of the other volumes, deals with silicosis and other pneumonoconioses, industrial carcinogenesis, and toxicology. It offers an exhaustive but, for the average physician, somewhat hard-to-understand account of the chemistry, enzyme reactions, and derangements involved in the various industrial intoxications. This work is well written. It is an authentic source of valuable information; guidance, especially for the British; and references, particularly on industrial and compensation medicine, rehabilitation, toxicology, and, to a lesser extent, industrial hygiene.

British Postgraduate Medical Federation, University of London, Lectures on the Scientific Basis of Medicine. Volume IV: 1954-55. Cloth. $6.50. Pp. 397, with 34 plates. Athlone Press, University of London, 2 Gower St., London, W.C.1, England, John de Graff, Inc., 31 E. 10th St., New York 3, 1956.

This volume contains 21 lectures, most of them very interesting, on a variety of medical subjects; each is by a different speaker. It will probably be most appreciated by medical students as a book to be picked up from time to time to furnish inspiring sidelights on anatomy, biochemistry, and physiology. A chapter on the chemistry of the porphyrias, for instance, includes photographs showing the devastating physical effects of this metabolic disease. A chapter on nucleoproteins in cell structure shows how the ability of these complicated, three-dimensional molecules to duplicate themselves is involved in most processes of growth and reproduction. A chapter on the cooling of the whole organism gives recent results on artificial hibernation, considers the danger and prevention of cardiac fibrillation in hypothermia, and sketches possible applications in surgery. The chapter on alcohol contains much scientific information enlivened by a discreet touch of humor. Other topics that will appeal to the medical student include the chemical aspects of abnormal growth, shock from burns, radiation injury to bones, and the effects of distention of viscera. The book also offers chapters that will be especially appreciated by physicians seeking coherent summaries of recent developments in the basic sciences; some of these chapters are entitled The Plasma Proteins, Laboratory and Clinical Findings in Hypersensitivity, Reaction of Enzymes to Injury, and Fat Metabolism. The book lacks an index, but each chapter includes a bibliography. The illustrations are excellent.

The Practice of Psychosomatic Medicine as Illustrated in Allergy. By Hyman Miller, M.D., *Associate Clinical Professor of Medicine, University of California at Los Angeles, Los Angeles, and Dorothy W. Baruch, Ph.D.* Cloth. $5. Pp. 196. *Blakiston Division,* McGraw-Hill Book Company, Inc., 330 W. 42nd St., *New York 36; 95 Farringdon St., London, E.C. 4, England, 1956.*

This book, *written by an allergist and* psychologist, is mistitled, for it is not a treatise on the practice of psychosomatic medicine but rather a monograph on the psychosomatic approach to allergy. Its focus is on allergic patients, and, although much significant information is contained about the role of the psyche in the sufferings of such patients, general applications for the whole field are not discussed. The authors contend that the allergic patient, like any sick person, can only be understood in the context of his total family situation. Both the allergic constitution and the emotional climate of the family are significant in the production of the disease. Emotional factors act as trigger mechanisms for the production of the symptoms. The task of diagnosing these factors in adults and children requires special technical procedure, and their treatment is effected by means of special skills not transmitted through reading. The book is simply written and easily understandable. The authors recognize that emotional factors are but a part of the total allergic syndrome, and this part they present well. Reading the book may stimulate allergists to obtain more *training in psychodynamics or to greater* willingness for cooperation with psychiatrists. The bibliography and index are barely adequate.

Surgical Forum. Volume VI. Proceedings of Forum Sessions, Forty-First Clinical Congress of the American College of Surgeons, Chicago, Illinois, November, 1955. *Surgical Forum Committee:* Harris B. Shumacker, Jr., *chairman,* and others. Cloth. $5. Pp. 654, with illustrations. American College of Surgeons, *40 E. Erie St., Chicago 11, 1956.*

Beginning with this volume, the American College of Surgeons has itself assumed responsibility for publication of the annual "Surgical Forum." The contributions cover the fields of general surgery, neurosurgery, gynecology and obstetrics, orthopedics, plastic surgery, and urology. The contents of the volume reflect most of the advances in these fields and point toward further studies in clinical surgery. The printing, binding, and illustrations are of the same excellence that characterized the previous volumes.

Joint Ligament Relaxation Treated by Fibro-Osseous *Proliferation.* By George Stuart Hackett, M.D., F.A.C.S., Consulting Surgeon, Mercy Hospital, *Canton, Ohio. With special reference to low back disability—trigger point pain and referred pain.* Cloth. $4.75. Pp. 97, with 17 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell *Scientific* Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson *Press,* 299 Queen St., W., Toronto 2B, Canada, 1956.

This monograph propounds the theory that most backache and pain in or about other joints is due to chronic relaxation of ligaments. While it is true that chronic relaxation of ligaments may and does at times produce localized and referred pain, such as the author has described and treated by his method of injection, there are many other conditions, such as fibrositis, bursitis, or chronic edema at the insertion of ligaments or tendons, that frequently cause local soreness and referred pain. Although it may not be possible to agree with the author that the cause of localized tenderness and referred pain is mainly relaxation of ligaments, the treatment he advocates is logical for many of the conditions that produce backache with referred pain. Many orthopedists have found the use of a local anesthetic for the injection of "trigger points," with or without the added injection of other substances such as hydrocortisone or a mild irritant, to be helpful in relieving this painful syndrome. This is an interesting and challenging book, but some of the statements found in it will not be accepted by most orthopedists. The report of such a high incidence of recovery of the patients treated by the author should cause all physicians whose minds are not closed to new ideas to study the methods used and put them to the therapeutic test.

Ciba Foundation Colloquia on Endocrinology. Volume 9: Internal Secretions of the Pancreas. Editors for Ciba Foundation: G. E. W. Wolstenholme, O.B.E., M.A., M.B., and Cecilia M. O'Connor, B.Sc. Cloth. $7. Pp. 292, with 100 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., Portman Sq., London, W.1, England, 1956.

The present colloquium is a follow-up of a previous one dealing with carbohydrate metabolism that was held by the Ciba Foundation in 1952. A group of American and European workers reviewed their recent experimental studies in this field. Their reports as well as the discussions that followed each report summarize most of the research that is now being conducted. The subjects treated are the effects of agents that specifically alter the alpha cells of the pancreas, glucagon, the chemical structure and configuration of insulin, the permeability of cells to glucose and other sugars, the hepatic actions of insulin, and the interactions of pituitary growth hormone and insulin in the organism. Since the book deals primarily with animal experiments, it will be of primary interest to the research worker rather than to the clinician. The demonstration, however, that destruction of the islet tissue affects carbohydrate metabolism quite differently than does pancreatectomy and the observed actions of the hyperglycemic glycogenolytic factor of the alpha cells may alter radically our present notions of the pancreas and carbohydrate metabolism and may have practical clinical significance. As with the other volumes in this series, the editors and publishers have produced a well-written and excellently printed book.

Fluid Balance Handbook for Practitioners. By William D. Snively, Jr., M.D., *Attending Physician, Evansville Child Health Clinics,* and Michael J. Sweeney, M.D., Attending Physician, Evansville Child Health Clinics, Evansville, Ind. Cloth. $6.75. Pp. 326, with illustrations by Kathleen Calhoun. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, *England; Ryerson Press,* 299 Queen St., W., Toronto 2B, Canada, 1956.

This is an exceedingly well-written book by two authors who are well qualified to discuss this subject. They have presented all the problems of fluid imbalance in a simple logical fashion. The types and composition of body fluids and their shifts are specifically discussed. Electrolyte imbalance and all the clinical problems of acid-base equilibrium are included, and the methods of handling these problems are discussed. Specific instructions for determining amounts, kind, and rate of fluids are suggested by a simple set of rules. There are actual case problems presented at the end of the book as exercises for handling specific imbalances. This small volume can be read in a few hours. The format is pleasing, and the illustrations, figures, and tables are excellent. The bibliography is rather scant. This book can be recommended to all students and to practioners of medicine and surgery who are confronted with problems of fluid imbalance.

Textbook of Urology. By Victor F. Marshall, M.D., F.A.C.S., Associate Professor of Clinical Surgery (Urology), Cornell University Medical College, New York City. Cloth. $5.50. *Pp.* 268, with 66 illustrations. Paul B. Hoeber, Inc. (*medical book department of* Harper & Brothers), *49 E. 33rd* St., New York 16, 1956.

This book represents a needed concise, accurate urologic textbook. The contents are well arranged and presented in a straightforward manner. The urologic concepts are those current in the field of diagnosis and treatment. The diagrammatic representation of urologic disease as a pyramid leading to a cure is clever. The base of that pyramid is an adequate history and physical examination, tools available to all interested physicians. The text reads easily and is occasionally interspersed with appropriate comments. This book is recommended for medical students and practicing physicians.

QUERIES AND MINOR NOTES

LIGHTNING PAINS

To the Editor:—*A 42-year-old man contracted syphilis in 1938, after which he had a course of treatment of bismuth and mercury. This course was completed in 1944, and since then he has had penicillin ranging up to 6 million units. The primary symptom at present is apparently that of a neuritic pain largely involving the knees. X-ray revealed no evidence of syphilitic involvement, and neurological examination is negative. He has a persistently positive reaction to the Wassermann, Mazzini, and Venereal Disease Research Laboratory tests. The pain this man is experiencing can be dulled with aspirin, Empirin, or Demerol, but not completely relieved. Otherwise he is in good health and is able to work in the oil fields regularly. What course of treatment might be available for prevention of the pain or at least a check of its frequency?*

M.D., Montana.

Answer.—The information provided is inadequate to permit an opinion as to whether the neuritic pain primarily involving the knees is or is not potentially associated with the patient's long-standing syphilitic infection. So-called neuritic pains in patients with late syphilis are practically always characteristically lightning or lancinating in character. The character of the pain is sharp, stabbing, and knife-like, each individual pain lasting only for a second or a fraction thereof. These pains tend usually to occur in the lower extremities and are characterized by the fact that they shift from one place to another, sometimes in a toe or sometimes in the ankle, the calf, the knee, or the thigh. They tend to occur in attacks of varying severity, ranging from minor inconvenience that is readily relieved by a mild analgesic, such as aspirin, up to attacks of agonizing severity that may require large doses of morphine or other powerful analgesics. The individual attack of pain may last for an hour or two only or may continue for days at a time. In most cases, the attack ceases either spontaneously or after administration of analgesic drugs, and the patient is completely free from discomfort in the interval between the attacks. This interval may vary from days or weeks to months. An extraordinary feature of this type of pain is that the attacks may be precipitated or triggered by several widely varied circumstances, including a change in the weather, an elevation of body temperature, the presence of focal infection, fatigue—whether physical or mental—and constipation. The attacks are only occasionally completely relieved by any form of antisyphilitic therapy, whether metal or antibiotic chemotherapy, though some patients may obtain partial relief in terms of lessened frequency and severity of attacks.

The diagnosis of lightning pains depends entirely on the patient's description of his subjective discomfort, plus, in most cases, associated neurological evidence of tabes dorsalis. The pains are due to involvement of the posterior roots and columns of the spinal cord and may constitute the earliest symptom of tabes, appearing before there are objective evidences of neurological damage. Pains of this nature do not occur in any other condition. If the patient's pain is of the nature described, it seems reasonably certain that it is due to the old syphilitic infection and that confirmation of this may be had either by very careful neurological examination, with particular reference to objective evidence of damage to posterior columns of the spinal cord, and/or by examination of the cerebrospinal fluid, which does not appear to have been done. The management and treatment of lightning pains often call for the highest skill in the art of medicine, with many ancillary factors to be considered other than antisyphilitic treatment itself. In this particular patient, if the neuritic pain does not conform to the description given above, it is highly improbable that these pains have anything to do with syphilis.

TOXICITY OF 2,4-DICHLOROPHENOXYACETIC ACID (WEED SPRAY)

To the Editor:—*A farmer who has been perfectly well began using 2,4-dichlorophenoxyacetic acid (2,4-D) to spray weeds several weeks ago. He inhaled considerable spray, after which he had a burning sensation in the throat and chest, became weak, and lost his appetite and some weight. Examination of the urine revealed nothing except 2+ albumin, with no casts or blood cells. On discontinuing use of the spray, he gradually improved and the urine has cleared up. This trouble came on also last year and the year before when he used the same spray. On two occasions, he had two other men helping him, both of whom became ill in a similar manner, requiring several weeks for recovery. In the July 18, 1953, issue of* The Journal, *page 1144, the following statement appeared in an editorial "Relief from Ragweed": "2,4-D is comparatively harmless to animals and humans." The article also states that "the dusts of 2,4-D can be irritating to the eyes and respiratory tract," but no reactions were mentioned that were as severe as apparently occurred in these people. Could this illness be due to inhalation of 2,4-D?*

W. E. Wilson, M.D., Northfield, Minn.

Answer.—All available evidence tends to indicate that the sodium salt of 2,4-D is relatively nontoxic when wet or dry clouds are inhaled. Animal experiments with this material did not produce any evidence of lung irritation; however, in concentrated form it is likely to be irritating. The oral $L. D._{50}$ for mice is about 280 mg. per kilogram. Injection of 150 to 200 mg. per kilogram produced myotonia followed by sluggishness and shallow respiration in mice. There is a possibility of individual sensitivity to 2,4-D in persons susceptible to phenol compounds; 2,4-D formulations contain petroleum distillates that may cause varying degrees of discomfort. This factor should be taken into consideration in complaints after exposure to this class of herbicides.

SIDE-EFFECTS OF RADIOTHERAPY

To the Editor:—*Has the value of nicotinamide been scientifically demonstrated for the prevention of the side-effects of radiotherapy? In the city, most of the radiologists routinely prescribe liver extracts and/or vitamin B_{12} for patients exposed to x-rays to prevent postradiotherapeutic leukopenia and anemia. This practice seems illogical, particularly in leukemias and allied disorders, because well-conducted radiotherapy is likely to relieve a preexisting anemia and not aggravate it and these substances probably further the development of the leukemic cells. Are these assumptions correct? What about the use of glutathione, cysteine, thymonucleic acid, and cortisone to prevent the side-effect of radiotherapy?*

Jacques Messerschmitt, M.D., Algiers, Algeria.

Answer.—There are two categories of side-effects of radiotherapy to be considered: First, nausea, vomiting, and malaise after treatment and, second, leukopenia and depression of platelets and eventual anemia. In the first category, derivatives of vitamin B complex, such as nicotinamide or nicotinic acid, with or without pyridoxine hydrochloride, have been helpful on clinical trial. Gravidox, which is a mixture of 20 mg. of pyridoxine hydrochloride and 20 mg. of thiamine hydrochloride, three tablets three times a day, may be helpful. In regard to the second category, leukopenia and depression of platelets may follow total body irradiation or treatment over large areas of the body as commonly given for lymphomas and leukemias. There is no reason for routine administration of liver extract and vitamin B_{12} for this difficulty. Small doses of cortisone acetate, usually 25 mg. given twice daily, until the white blood cell count returns to normal, may be helpful in many cases. Many experiments with animals have been reported using glutathione and cysteine after heavy doses of total body irradiation, but it is not believed that these substances have been used to any extent clinically.

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

POSTNASAL TAMPON FOR NASAL HEMORRHAGE

To THE EDITOR:—*Is there information available on the origin of the routine postnasal pack used for nasal hemorrhage?*

Ernest E. Alvin, M.D., San Francisco.

ANSWER.—A brief mention of the postnasal tampon technique was given by Philipp Scheck in 1884. The historical documentation of this procedure is not so simple, as it means ferreting out of a case description of such a technique that might be so identified. Priority is lost in antiquity and may not be well established, but one of the best descriptions was offered by P. McBride in his "Diseases of the Throat, Nose and Ear" (ed. 2, Philadelphia, P. Blakiston's Son and Company, 1894, pp. 272 and 273). It follows: "If it is desired to plug the posterior nares a small-sized, soft rubber catheter is the best instrument to employ. To its extremity is attached a string of sufficient length. The point is now passed into the nostril, while the patient sits, with open mouth and light thrown on the pharynx, before the surgeon. When the latter sees the catheter appear below the palate he seizes it with dressing forceps, and pulls it and the attached string out through the mouth. A pledget of lint, preferably saturated with vaseline, to which some antiseptic has been added, if there be a prospect of the plug having to remain *in situ* for any length of time—is now attached to the string about 18 inches from its extremity, and pulled up behind the palate, after which the two projecting strings are tied together. It is often useful at this juncture, to introduce the finger to guide the pledget past the uvula and soft palate. If it be only desired to plug the anterior nares, a long strip of lint—saturated with vaseline to prevent sticking—is pushed in by dressing forceps. Plugs produced by distending membranous or india rubber bags, with air or fluid, have been employed, but they seem only complicated methods of arriving at the same result."

INSECTICIDAL FOGGING OF HOSPITAL GROUNDS

To THE EDITOR:—*We purchased an insecticidal fogging machine in an endeavor to control mosquitoes and flies in the vicinity of the hospital grounds. The active ingredients in the insecticide used are chlorophenothane, 8%; isobornyl thiocyanoacetate, 1.55%; related terpenes, 0.45%; and petroleum distillate, 92.5%. Please advise as to the danger, if any, to human and plant life and, also, as to the precautions to be taken and/or substitutes to be used in the fogging procedure to rid the area of mosquitoes and flies.*

Louis J. Ptacek, M.D., Oconomowoc, Wis.

ANSWER.—If the fogging is done by responsible and trained persons acquainted with the dispersal of such preparations, it is rather unlikely that members of the hospital community would be exposed to dangerous amounts of the material from either acute or chronic toxicity viewpoints. Contamination of fruit or vegetables in gardens or in the hospital is equally unlikely because of the nature of the dispersal and the small quantities of the insecticidal materials used. Persons suffering from asthma or hay fever might experience respiratory difficulty if they were in immediate contact with the fog. Fogging operations, however, are usually conducted after sundown, or later in the evening, and at distances of 25 to 50 ft. from the nearest dwellings. The nature of the dispersal and the meteorologic conditions for successful fogging operations are such that gross exposure to fogs by such persons can be readily avoided. Wildlife is reported to be not injured when large areas of forest are fogged with chlorophenothane. Birds, bees, butterflies, and other forms of beneficial life commonly seen around residential areas are also probably safe for the same reasons.

TREATMENT OF HYPERPIGMENTATION

To THE EDITOR:—*I would like information regarding the use of monobenzyl ether of hydroquinone in the treatment of hyperpigmentation of the skin.*

E. G. Kettelkamp, M.D., Monona, Iowa.

ANSWER.—Monobenzyl ether of hydroquinone (MBH) is the only known chemical agent that inhibits the formation of melanin pigment when applied to the skin. Other drugs, including the so-called bleach creams, bring about an apparent decrease in skin pigmentation by exfoliation of the outer pigmented horney layer. Although MBH is an effective topical agent for decreasing melanin pigmentation, it has several major disadvantages: 1. About 13% of patients develop a contact dermatitis. 2. The decrease in pigmentation is very slow, requiring six to nine months in some patients. 3. The resulting depigmentation is often not uniform but mottled, especially in the Oriental and Negroid races. 4. For some unknown reason MBH is effective in only a relatively small percentage of patients treated. The use of MBH should therefore be limited to disfiguring melanin hyperpigmentation in the Caucasian race. If no effect is noted after 9 to 12 months of application, therapy should be discontinued. MBH, being an inhibitor of melanin formation, has no effect on pigmentation resulting from iron, silver, or artificial pigments. A commercially available ointment contains 20% MBH in a washable base.

FISH POISONING

To THE EDITOR:—*A patient in Havana, Cuba, had an acute episode of diarrhea lasting seven days. He claimed to have eaten fresh broiled barracuda meat, which he caught himself. Even though the barracuda is a man-eating fish, is there any special reason why this type of fish poisoning is different from other fish or shellfish poisoning?*

C. D. J. Generales, M.D., New York.

ANSWER.—Fish poisoning resulting from the ingestion of fresh (unspoiled) barracuda is generally classed under the syndrome known in the Caribbean area as ciguatera. More than 300 species of fish have been reported as being capable of producing ciguatera-like symptoms. Prolonged diarrhea is a common component of this complex. The only relationship between the barracuda's man-eating tendencies and its toxicity is its size, i. e., only the larger specimens are likely to be dangerous. Shellfish poisoning is caused by a toxic substance found in certain marine protozoa (dinoflagellates), on which the shellfish inadvertently concentrate for food during certain seasons of the year. The poisonous substance that produces shellfish intoxication is not the same as that which produces ciguatera-like symptoms.

BCG VACCINATION

To THE EDITOR:—*May I point out in answer to the query entitled "Exposure of Children to Tuberculous Grandmother" (J. A. M. A. 161:926 [June 30] 1956) that I would recommend BCG vaccination if the grandchildren have a negative reaction to the tuberculin test. Six to eight weeks after vaccination, if the children's reactions to the tuberculin test have become positive, let them visit the grandmother, who I assume is receiving antimicrobial treatment. I would have the grandmother as well as the children take the accepted precautions against infectious disease. This advice is based on my long experience, both in the laboratory and in the field, with the use of attenuated, viable tubercle bacilli as immunizing agents against tuberculosis and is supported by the experiences of other investigators. The consultant's answer has become practically a slogan for those who have had little experience with immunizing agents in tuberculosis and has also been used by opponents of other forms of vaccination and treatment. It would be of interest to readers of* THE JOURNAL, *and to those of us engaged in the study of immunization against tuberculosis, if the consultant would present the statistical data on which he bases his statements and compare them with the data of Ferguson, Rosenthal, the Medical Research Council, myself, and others who have evaluated BCG vaccine under control conditions.*

In support of my own views, may I summarize a study, which was initiated in 1936 and which culminated in 1956, to determine under field conditions the value of BCG vaccine. A group of 1,551 children of preschool and school age who had negative reactions to the tuberculin test received an intracutaneous injection of BCG vaccine and were not revaccinated. A group of 1,457 children of comparable age and sex who had negative reactions to the tuberculin test received an intracutaneous injection of saline solution and served as controls. An analysis of 26,580 roentgenograms of the chest taken annually for the first 9 to 11 years of this study showed that 4.1% of the vaccinated and 16.4% of the control patients showed *tuberculous lesions—0.7% miliary in nature, none among the vaccinated; 12.5% and 14.8% of the vaccinated and control patients, respectively, showed nontuberculous lesions. An appraisal of the protective value of BCG vaccine, 15 years after the initiation of the same study, was published in* THE JOURNAL *(149:334 [May 24] 1952) by C. F. Aronson and me. At that time, 12 of the vaccinated and 65 of the control patients had died of tuberculosis while 59 and 63 of the vaccinated and control patients, respectively, had died from nontuberculous causes. Of the 65 deaths from tuberculosis, 19 had been due to miliary tuberculosis. None of the vaccinated patients had died from this form of tuberculosis.*

In 1956, 18 to 20 years after the initiation of the study, we again determined the mortality from all causes and from tuberculosis among the 3,007 persons in the study, and traced all but 24 persons. At this time we found that 13 of the vaccinated and 68 of the control patients had died from tuberculosis, 45 of the vaccinated and 42 of the control patients had died from nontuberculous diseases, and 44 of the vaccinated and 40 of the control patients had died from the results of violence.

The preliminary report of the Medical Research Council, published in the British Medical Journal, *Feb. 25, 1956, shows that among over 50,000 adolescents followed in this study the annual incidence of tuberculosis was 0.37 per 1,000, compared with 1.94 per 1,000 among the control patients. Will the consultant cite any reference indicating that multiple cases of tuberculosis have followed the use of BCG vaccine from one laboratory or from one lot of vaccine?*

Joseph D. Aronson, M.D.
Henry Phipps Institute
Philadelphia.

RESEARCH REVIEWS

From time to time there will be published in this section of THE JOURNAL *brief but not necessarily complete reviews of some of the newer clinical aspects of medical research and practice. This material is gathered specifically for* THE JOURNAL.—ED.

NONSPECIFIC DEFENSE MECHANISMS OF THE BODY

Current interest in the study of natural resistance to infection found expression at a conference of the New York Academy of Sciences, Section of Biology, in New York. The mechanisms of "general resistance" are being unraveled gradually. There are several independent defense systems by which the body guards against invading bacteria, viruses, and protozoa. Some of these mechanisms have been defined recently.

The Properdin System.—The recognized components of the properdin system are properdin, complement, and magnesium ions.[1] According to its discoverer, L. Pillemer,[2] Western Reserve University, Cleveland, properdin is a euglobulin that contains lipid, carbohydrate, and phosphorus. It is normally always present in the serum of man and mammals without previous antigenic stimulation. Serum from rats reared under sterile conditions contains a normal amount of properdin. Properdin is not an antibody. Its action is nonspecific. To become active, properdin requires complement (C′) and magnesium ions.

While it was thought in the past that the presence of antibody is necessary for the action of complement, the discovery of the properdin system has demonstrated that complement also plays a part in bactericidal defense mechanisms that act in the absence of specific antibodies. Four components of complement have been identified: C′1, C′2, C′3, and C′4. All four components are essential in the properdin system. To kill gram-negative bacteria, for instance, C′1, C′2, C′3, C′4 and magnesium ions must be present.

Magnesium in the properdin system cannot be replaced by sodium or calcium. Under experimental conditions—and only in unphysiologically high concentrations—cobalt or manganese may replace magnesium. Thus, under normal circumstances, magnesium plays an essential part in the body's natural defense against infection.

Normal human serum contains 4-8 units of properdin per milliliter, rat and mouse serum 25-50 units, and guinea pig serum less than 3 units. One may speculate whether these species variations reflect differences in natural resistance to infection. Stray dogs have a properdin level that varies from the normal for dogs of 12 to 18 units per milliliter to near 0. In some areas, especially in the South, stray dogs have an almost uniformly low titer. If they are given proper care and good food, their titer can be restored to a normal level.

In normal individuals the properdin level remains constant. It bears no relation to age or sex. L. Pillemer[3] and C. F. Hinz Jr. and J. R. Murphy,[4] Western Reserve University, Cleveland, have reported that fever, variations in the leukocyte count, and some other factors do not influence the properdin level. In patients with infections due to gram-negative bacteria, pneumococci pneumonia, and paroxysmal nocturnal hemoglobinuria, it has been found that the properdin level is low.

In vitro, the properdin system present in normal human serum destroys bacteria, inactivates viruses, kills protozoa, and lyses abnormal erythrocytes. In experimental animals, there appears to be a relation between the serum properdin level and shock, susceptibility to bacterial invasion after irradiation, and resistance to infection in general.

J. Fine, Harvard Medical School, Boston, and his collaborators have found that hemorrhagic shock in dogs reduces the serum properdin level considerably, while there is no change in the total and differential leukocyte count or in the hemolytic activity of complement in vitro.[5]

O. A. Ross,[6] Western Reserve University, Cleveland, has reported that total body irradiation of mice results in a profound drop in the properdin level and fatal bacteremia. The effects of the administration of properdin under these circumstances have been studied. When properdin is given during the postirradiation period, it partially protects the animals and prevents death. When it is given too early, it does not prevent the onset of bacteremia. Pillemer believes that it may be dangerous to give properdin at the height of bacteremia, since its bactericidal action may release such an overwhelming amount of endotoxin at one time as to cause toxic shock and death.

The bactericidal action of the properdin system has been demonstrated.[7] When bacteria invade the blood stream they are attacked immediately. This is a nonspecific effect. Specific antibodies in response to antigen stimulation are only formed after several days. The properdin system thus forms the first defense. Its action is supplemented by the formation of antibodies that deal with the surviving bacteria.

According to D. Rowley,[8] St. Mary's Hospital, London, England, the lipopolysaccharide fraction in bacterial cell walls may be the substrate for the serum bactericidal reaction. He found that following the injection of cell walls of various gram-negative bacteria there were changes in nonspecific immunity to experimental infection with Escherichia coli and Salmonella typhosa. In addition to these organisms, M. Landy,[9] Army Medical Service Graduate School, Washington, D. C., has shown that injection of lipopolysaccharides into mice also causes a transient increase in nonspecific resistance to experimental infection with Proteus vulgaris and Pseudomonas aeruginosa. This increase in resistance following bacterial lipopolysaccharide injection is accompanied by elevated properdin titers.[10]

Highly purified lipopolysaccharides have been prepared.[11] Lipopolysaccharide from Salmonella abortivoequina is a powerful pyrogen, and its effects when injected into man have been studied.[12] The question yet to be answered is whether injection of such lipopolysaccharides prepared commercially offers a practical way of raising the properdin level clinically.

Fresh normal serum inactivates influenza A and B, mumps, Newcastle disease, and vaccinia viruses; in conjunction with antibody, it also inactivates Rous sarcoma, Western equine encephalomyelitis, herpes simplex, and dengue viruses. It is inactive against poliomyelitis and the recently described adenoviruses. H. S. Ginsberg and R. J. Wedgwood,[13] Western Reserve University, Cleveland, have shown that the properdin system inactivates the virus of Newcastle disease. There is no evidence yet as to the role that the properdin system may play in natural or acquired immunity to viral infection in man. The heat-labile component of normal serum reported in 1949, which neutralizes virus infectivity and inhibits hemagglutination,[14] is probably identical with properdin.[1]

Also, the heat-labile serum components and magnesium required for toxoplasma antibody to exert its adverse effect upon the parasite may be identical with the properdin system, according to H. A. Feldman,[15] State University of New York, Syracuse, and other workers.[16]

Recent studies in man [17] indicate that various types of anesthesia, elective surgery, accidental trauma, adrenalectomy, and removal of the spleen do not cause significant changes in the serum properdin titer. The properdin level has been found to be depressed in certain surgical cases in association with peritonitis, pneumonitis, atelectasis, paralytic ileus, gastrointestinal hemorrhage, and wound infection following burns. In a few patients subjected to extreme variations in corticosteroid maintenance therapy after adrenalectomy, no significant changes in serum properdin titer were noted.

At present, properdin is not available for clinical use. Two ways of increasing the amount of naturally occurring properdin are being considered: (1) the injection of lipopolysaccharides and (2) the fractionation of plasma.

Little is known yet about the practicability of the first method. The second method is under intensive study in Boston. Since the preparation of properdin from serum presents a number of difficulties, plasma from blood collected over an exchange resin is being used. Initial laboratory production promises a yield of about 1 million units of purified properdin per year. With pilot plant production, it should be possible to increase this yield to about 6 million units per year, and with other measures now contemplated perhaps to more.

Before properdin can be made available for clinical use, problems of sterility, stability, and freedom from pyrogenic and other untoward effects must be solved. J. Fine estimates that an adult depleted of properdin may require a therapeutic dose of as much as 10,000 to 20,000 units; hence the amount for clinical investigation that may be expected for the time being will be very little indeed.

Other Defense Mechanisms.—J. L. Tullis and D. M. Surgenor,[18] Harvard Medical School, Boston, have reported the isolation of two new proteins that control the ability of leukocytes to ingest bacteria. They were isolated from plasma. One is a betaglobulin; the other, an alpha-1 globulin. They are different in their chemical behavior, but similar in their physiological activity of promoting phagocytosis. They have been called phagocytosis-promotion factors. Purified preparations of properdin have no phagocyte-stimulating effect.

J. G. Hirsch,[19] the Rockefeller Institute for Medical Research, New York, has investigated the mechanism that leads to intracellular death of engulfed micro-organisms. He believes that lysozyme present in polymorphonuclear leukocytes does not account for the bactericidal power of these cells, since many micro-organisms insusceptible to lysozyme are killed in phagocytic cytoplasm. He has isolated a specific protein from the cytoplasm of polymorphonuclear leukocytes, which is thought to be responsible for the bactericidal action. The name phagocytin has been proposed for this protein. Its enzyme type of action is different from that of previously known antibacterial agents derived from tissues.

The study of these and other factors that may play a role in the natural defense mechanisms of the body is being actively pursued.

Military Dependent Medical Care Program Starts • •
FDA Administrator Again Denounces Hoxsey Clinics • •
State-by-State Study of Higher Education Urged • •
Plans for Hearings on Medical Education Dropped • •

MILITARY DEPENDENT MEDICAL CARE

On December 7, the Defense Department inaugurates a large new medical care program, designed to give uniform benefits outside military medical facilities to perhaps as many as 1 million wives and children of members of the uniformed services. Army Surgeon General Hays describes it as "the beginning of a new era in medical care and one that may set a new pattern in cooperation between civilian and military medicine."

At the outset at least, all wives and children will have freedom of choice between military and private facilities. If their choice is the latter, the new program provides that the federal government will pay most of the expense of hospitalization and preoperative and postoperative services. In civilian facilities, outpatient service is strictly limited. If, after a period of trial, the Secretary of Defense finds that military medical facilities are not used sufficiently, he may restrict private care in certain areas.

In military facilities, dependents will pay $1.75 per day. In private facilities, they will be charged the same fee or a total of $25, whichever is the larger. Other expenses will be met by the government. Financial arrangements will be handled by Blue Cross and commercial insurance companies for the private hospital phase. The medical care phases will be handled by arrangements worked out on a state-by-state basis by state medical societies and the Department of the Army, which is agent for the Defense Department in administering the program. Some societies are handling the medical care bookkeeping themselves, while others have entrusted it to Blue Shield or other organizations.

Dependent parents and parents-in-law of members of the uniformed services will be entitled to care on a space-available basis in military facilities but are not covered by the civilian program. In addition to the Army, Navy, and Air Force, the new program also includes dependents of members of the Coast and Geodetic Survey, the Coast Guard, and the commissioned corps of the U. S. Public Health Service.

In explaining the program's objectives shortly before the starting date, General Hays emphasized that the most important feature was the provision of medical care to service families "who heretofore could not avail themselves of medical service in uniformed facilities because of distance and overtaxed facilities." He added: "Until operating experience is gained, no firm evaluation of the impact of the program on the uniformed medical services can be made. At the present time, however, significant changes in personnel and bed requirements do not appear likely."

He said that, if the program produces the results hoped for, "it should be important in promoting career service to a greater percentage of our forces. If only a small percentage of the one million men we lose annually can be retained through the provisions of this legislation, then it will pay for itself many times over."

From the Washington Office of the American Medical Association.

HOXSEY CANCER REMEDY

Following upon a federal court condemnation of the Hoxsey medicines as "illegally offered as an effective treatment for cancer," the U. S. Food and Drug Administration warns all cancer patients and their families that "this action does not end the meances of this fake treatment." A statement by FDA Administrator George P. Larrick reviews the action of the Pittsburgh court, stating that this "merely means that half a million of the Hoxsey pills, which were seized shortly after the opening of a second Hoxsey Clinic at Portage, Pa., will now be destroyed." The FDA will seek an injunction to stop further interstate shipment of the pills. Adds Mr. Larrick: "We intend to use every legal means within our power to protect consumers from being victimized by this worthless treatment."

The statment says that it is "of the utmost importance" that cancer patients and their families who may be planning to employ the treatment at the Hoxsey clinics at Dallas, Texas, or Portage, Pa., should acquaint themselves with all the facts. They are advised to write the Food and Drug Administration in Washington for a copy of a public warning issued by the FDA last April.

The FDA statement continues: "Harry M. Hoxsey has continued to promote his worthless cure for more than 30 years, notwithstanding numerous local and state court actions. Proceedings under the Federal Food, Drug, and Cosmetic Act did not appear possible until a 1948 decision of the Supreme Court interpreting the word 'accompanying' in the definition of labeling under the Act. An injunction suit was field in 1950 and a decree finally issued by the Federal court at Dallas in 1953. Over the years thousands of persons have been deceived by the false claims for the Hoxsey liquid medicines and pills. At the Pittsburgh trial there was testimony concerning persons who may have died of cancer as a result of reliance on the Hoxsey treatment instead of seeking competent medical treatment in the early stages of their condition. The Government's evidence showed that alleged 'cured cases' presented by defense attorneys were people who did not have cancer, or who were adequately treated before they went to the Portage clinic, or died of cancer after they had been treated there."

GOVERNMENT-FINANCED STUDIES

A state-by-state analysis of higher education needs for the next 20 years, with the possibility of the federal government helping finance the studies, is proposed in the first interim report of the President's Committee on Education Beyond the High School. The report declares: "Even while the localized needs are thus being specified and defined by the state studies, consideration must be given to how and by whom . . . the increasing costs of supporting more individual students, training more teachers and building more buildings shall be borne. It is already clear that present resources will be grossly inadequate."

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, New York

Washington News—Continued

The committee said it will "weigh proposals for grants for teacher training, loans for other than self-liquidating buildings, grants for various kinds of physical facilities, construction of ROTC facilities at federal expense, and still other proposals that are already being considered by some legislators."

It scored the lack of any over-all educational policy, in the face of the fact that the federal government in recent years has spent more than a billion dollars in the field of education beyond the high school. "Over and above these separate programs, the federal government is now being called upon for an increasing number of other forms of support such as extension of loan programs, scholarship aids, especially for aspiring teachers, special 'crash programs' for production of doctors and even contributions toward vocational training. . . . The federal government has no clear and explicit policy to guide the consideration of such proposals."

The report also warned that the "inflexibility of the prevailing pattern of 12 years in elementary and secondary schools, four years in college and two, three or more years in professional school" was in conflict with contemporary social trends. "It fails to account for the varying aptitudes of students and for the cumulative effect upon their lives of the lengthening curriculum when coupled with existing obligations, earlier marriage ages and earlier retirement ages."

In expanding and diversifying opportunities or speeding up the formal educational process, the committee stressed, "we must never lose sight of the crucial importance of maintaining high standards, and we must be constantly alert to improve the quality of the educational offerings."

MEDICAL HEARINGS

Plans for a series of panel-type hearings on problems and needs in medical education originally set for this fall have been given up by the House Interstate and Foreign Commerce Committee. Changes in the make-up of the committee, including the death of Chairman Percy Priest, have forced abandonment of the hearings, at least for this year. Decision on whether to go ahead with a study of this type next session will hinge on the new chairman, Rep. Oren Harris (D., Ark.), and the reconstituted committee. The committee staff, meanwhile, is continuing to gather material on the financial needs of medical schools, and the supply and demand of medical school applicants, as directed by the committee just before the 84th Congress ended.

During debate last session on the bill for federal grants to help schools and other research centers build laboratory facilities, efforts were made on the House floor to broaden the measure to include money for classrooms. Congress decided instead that this subject needed more study. Original plans for the Interstate Committee hearings called for witnesses representing the professions, the medical schools, and various groups utilizing doctors' services to appear on a series of panels. The panel approach to legislation was used several years ago by former Chairman Charles Wolverton (R., N. J.), in investigation into broad health problems and again on the Salk poliomyelitis vaccine situation.

MEDICINE'S FUTURE

"Whether there is further government intervention in the field of medicine will depend largely upon medicine's willingness to carry the torch of free enterprise for the private practice of medicine," Dr. David Allman, President-Elect of the American Medical Association, told delegates to the Southern Medical Association convention, meeting in Washington, D. C.

The association's four-day golden anniversary meeting was attended by more than 5,000 physicians and guests. Dr. Allman's speech, at the last general session, was part of a program that included presentation of over 300 scientific papers and a symposium on industrial health. Panel members included Dr. Elmer Hess, past-president of the A. M. A., and Bradshaw Mintener, former Assistant Secretary of the Department of Health, Education, and Welfare.

Dr. Allman, in his address entitled "Who's Going to Carry the Torch," pointed out, "Today the threat of government intervention in medical affairs and in the relationship of doctor and patient is more imminent than ever before." He then stressed, "Our first responsibility is still to provide good medicine and good service to our patients at home. If we do this, we will be held in high regard by the people we serve. Then, and only then, will our chances of success on the political front be improved." At this general session, Dr. J. P. Culpepper Jr. of Hattiesburg, Miss., was installed as the new president. He succeeds Dr. W. Raymond McKenzie of Baltimore.

MISCELLANY

An estimated 2.4 billion dollars, a 7% increase over 1955, was spent in the 1956 fiscal year for scientific research and development by the federal government. These statistics are from the report, *Federal Funds for Science*, V, of the National Science Foundation. . . . Gen. Alfred M. Gruenther will begin his term as president of the American Red Cross on Jan. 1. He is retiring as supreme allied commander in Europe. . . . The Federal Civil Defense Administration is augmenting its medical storage program by an emergency supply support program providing "distribution in depth." . . . In the coming year the Influenza Information Center of WHO will be located at the National Office of Vital Statistics. . . . Two Veterans Administration doctors have devised a test that they believe may prevent the fatal hemorrhages of cirrhosis of the liver. Excessive pressure of blood is measured by inserting a hollow needle into the spleen. . . . Water treatment works in 9,000 U. S. cities and towns have been listed by the Public Health Service as in need of repair. This is one step in a new program of federal grants to help in constructing water treatment works. . . . A centralized orthopedic shoes service has been established by the VA. The new system is designed to provide better service to the veterans and to save $50,000 to $60,000. . . . Employees of the VA hospital in Fort Lyon, Colo., will receive an incentive award of $4,360, the largest in the history of the VA. . . . The first phase of a program designed to select and train future executives at all levels has been started by the Veterans Administration. The program, brought about by a possible 49% loss of executives during the next five years through retirement, now pertains only to key officials in the central Washington office and in field stations.

(cont'd)

'LANOXIN' continues to offer the same advantages — only the name has been changed.

The full effects of each dose develop quickly to permit rapid appraisal of the need for additional drug. Moreover, the limits of the patient's therapeutic range, which may be reduced in the seriously ill, may be approached with relative safety because toxicity, if it develops, soon abates. For true balance and uniformity of therapeutic effect, prescribe 'LANOXIN' brand Digoxin.

Sincerely,

'B.W.&Co.'

TABLETS: 0.25 mg. (white) and 0.5 mg. (green)

ELIXIR PEDIATRIC: 0.05 mg. in each cc.

AMPULS: 0.5 mg. in 2 cc.

OCCUPATIONAL DEAFNESS

Meyer S. Fox, M.D., Milwaukee

• *A worker's hearing can be damaged temporarily or permanently by sufficiently loud occupational noise, whether explosive or continuous. Audiograms made before and during the course of employment are essential to a program of conservation of hearing; they are also essential for medicolegal purposes. Medical supervision is important. The physician who is consulted in disputes about cases of allegedly occupational deafness is on safe ground when he confines himself to statements of demonstrated fact and when he avoids suppositions. The otolaryngologist is especially qualified to collect the facts needed to conserve the hearing of workers and to prevent economic loss to employers from ill-founded claims.*

Occupational deafness is assuming increasing importance in our everyday life. Not only does it directly affect the workers and employers but also it concerns other segments of society. As physicians we are primarily interested in the medical and medicolegal aspects of the problem. As otologists we are concerned with the hearing and communication problems. Because of space limitation, it will be impossible to go into any detailed discussion. I shall therefore confine this paper to some personal recommendations and observations that I feel may be of interest and use to the practicing otolaryngologist.

Trauma

Occupational deafness as herein used denotes hearing loss in one or both ears. partial or complete, arising during the course of, or as the result of, one's employment. It may occur suddenly, as the result of traumatic injury, intense blasts, or explosions, or gradually, as the result of prolonged exposure to hazardous noise levels. Direct trauma to the ear usually results from blows, foreign objects, and burns due to sparks and molten metal. The local trauma to the area may be followed by perforation of the tympanum and infection and often is associated with a hearing loss of the conductive or mixed type. These injuries are usually unilateral and tend to heal with proper management. It has been my experience that burns of the ear canal and perforations of the tympanum due to sparks and molten metal are much more common than one would gather from current literature on the subject. Direct blows to the head can result in a hearing loss due to nerve damage, functional hearing tests revealing audiograms similar to those found in noise deafness.[1]

The term *acoustic trauma* is often used to include industrial noise deafness as well as the sudden hearing loss produced by loud noises such as blasts, explosions, and gunfire. Davis,[2] however, feels that the two conditions would better be described by separate terms, in order that one may logically distinguish between them. He therefore uses the term acoustic trauma to mean the immediate injury produced by one or a few exposures to intense sounds, as illustrated by the hearing loss resulting from blasts or explosions. Industrial noise deafness, on the other hand, is used to describe the loss of hearing that develops over a period of months or years of working in an environment of hazardous noise levels.

Noise

Noise has been defined as unwanted sound. It is the result of acoustic waves occurring at random frequencies and intensities. When the normal ear is exposed to noise at damaging intensity levels for a sufficiently long period of time, a temporary depression of hearing results, which disappears after a period of rest. This temporary hearing loss is called "temporary threshold shift." When the ears are exposed for longer periods or to more intense sounds, the hearing loss becomes more severe and the recovery is incomplete. That portion of hearing that never returns is referred to as *noise deafness.*

What are the effects of noise? We know definitely that noise can and does cause loss of hearing and that it interferes with communication. These are referred to as the auditory effects. The nonauditory effects of ordinary industrial noise are, in my opinion, vague and indefinite, the symptoms depending a great deal upon the personal motivation of the worker.

compensation laws concerning noise deafness. These questions are gradually being answered by authorative decisions of the higher courts of the various states.[4]

In reviewing the medicolegal problems, it is my opinion that the chief cause for dispute arises from the fact that there were no reliable records that could be used as a base line to determine the worker's hearing at the beginning of employment and during the course of employment. Another important controversial medicolegal development is that pertaining to the various methods for determining hearing loss and for converting this hearing loss in terms of percentage of hearing disability. That there are differences of opinions is established by the fact that various states have different approaches to the same problem. The American Medical Association and the American Academy of Ophthalmology and Otolaryngology recognized the inadequacy of the existing methods of determining hearing disability and a committee of eight persons was appointed to study the problem. After several years of study, this committee published a report on principles for evaluating hearing disability.[5] All otolaryngologists interested in the problem of industrial noise deafness are urged to study this report.

Hearing Conservation Programs

The otolaryngologist, by virtue of his special training, interest, and daily clinical experience with hearing problems, has the qualifications that enable him to be a consultant in the planning and management of industrial hearing conservation programs. In a previous publication[6] I pointed out that the three major objectives of such a problem are to (1) conserve the hearing of workers, (2) avoid unnecessary economic loss to employers, and (3) collect the facts and data in order to facilitate the accomplishment of the two foregoing objectives.

The first requisite of an effective hearing conservation program is a thorough sound survey of the working areas. Such a study is necessary to scientifically determine the frequency characteristics and intensity levels of the noise present in these areas. The information thus gained should indicate whether excessive noise levels are present and, if so, the amount and type of acoustical treatment and individual ear protection that might be required in such working areas. The next step is to obtain a suitable room for the performance of hearing tests. The testing room should be situated in an area that will permit the satisfactory performance of hearing tests without interference due to extraneous noises. In some cases acoustical treatment of existing rooms will result in a satisfactory reduction of the extraneous noises. In other situations acoustical treatment will not bring about the desired result. Where this is not feasible, prefabricated acoustical booths now commercially available provide a satisfactory place for the auditory tests. The personnel who are to do the testing should be sufficiently trained and supervised by the otolaryngologist so that they will develop skill and interest in this work. For the ordinary industrial hearing conservation program, only pure-tone air-conduction audiograms need be taken, and these can be made with a simple, portable, properly calibrated audiometer.

The next phase of the hearing conservation program is the installation of preplacement pure-tone audiometric tests of the workers. This is a must. The preplacement pure-tone audiogram is a base line from which all subsequent studies concerning the worker's hearing status are made. The records that are used should show the audiometric and otological findings and pertinent items of medical and industrial history. All workers exposed to high-intensity noise levels should have periodic checkups of their hearing.

The results of all hearing tests are reviewed and evaluated, and those workers who show significant hearing loss at the beginning of employment or during the course of employment are referred to the otologist for examination and further hearing studies. This procedure results in the establishment of accurate records that can be used for purposes of job-placement and of ear protection and as a base line for future audiometric studies. It also establishes valid records made by a qualified otologist that can be used in the event industrial claims of hearing loss arise at a later date. I am aware of the fact that many industries have purchased audiometers and have turned over the job of testing workers' hearing to health and safety personnel without adequate medical supervision. The records that are made are filed away for use in the event of future compensation claims. It is unnecessary for me to point out that this is not practicing good medicine.

It goes without saying that the ideal hearing conservation program would entail the removal of the noise at its source. The extent to which these measures can be expected to decrease noise levels varies with the machines, the operations, and the physical plant and is a matter better left to the acoustical and industrial engineers. In the areas where noise levels cannot be effectively reduced by means presently available, the hearing of workers can be protected by the use of ear plugs. Considering that any protective device to be inserted into the ear canal is essentially a foreign body, it becomes obvious that the supervision of this aspect of the hearing conservation program should be in the hands of medical personnel and that all necessary hygienic measures should be taken. It has been my experience that the big problem is gaining the acceptance and cooperation of the workers and of convincing them it is not a sign of weakness but only good sense to protect their hearing with ear protectors.

Summary and Conclusions

Occupational deafness is defined as hearing loss occurring during the course of, or as the result of, one's employment. The hearing loss may occur suddenly, as the result of direct traumatic injury or of explosions, blasts, or gunfire, or it may occur gradually, as the result of prolonged exposure to hazardous noise levels. As otolaryngologists, our interest and function is to conserve and protect human hearing. Therefore, it behooves us to meet the challenges of occupational deafness by active interest and participation in the various aspects of the problem.

ANESTHETIC MANAGEMENT OF PATIENTS WITH RESPIRATORY DISEASE

Nicholas M. Greene, M.D., New Haven, Conn.

• *Respiratory disease in a surgical patient can represent a serious complication to the giving of anesthesia. Preoperative management must include correction of the underlying pulmonary pathology, where possible. For preanesthetic medication, the barbiturates are preferable to analgesics. While the anesthetic agent itself cannot be related to any adverse effects on preexisting pulmonary infections nor, alone, have influence on postoperative respiratory complications, it must still be admitted no presently available agent or technique is ideal. The selected procedure must therefore be considered in the light of its particular advantages (e. g., bronchodilating qualities, rapid postoperative response) over predicted disadvantages (e. g., anoxia, respiratory depression). Competent postoperative supervision, preventing interference with adequate respiration, completes the program of providing safe anesthesia for patients with respiratory disease.*

One of the most frequently encountered problems in clinical anesthesia is that of the patient with respiratory disease. This problem deserves our careful attention. Unless it is successfully solved, the patient is subjected to an increased operative and postoperative morbidity and mortality, or surgery is so limited that the indicated procedure cannot be accomplished. Recent advances have been made that offer help in dealing with these patients. Although much yet remains to be learned, it is appropriate to consider some of the clinical ramifications of developments and, by combining them with older and well-recognized principles, to formulate a modern approach to this ancient problem. To limit an otherwise vast and complicated field, emphasis will be placed on those patients in whom the respiratory disease represents an incidental, albeit serious, complication to extrathoracic surgery.

Preoperative Management

Unless patients with respiratory disease are properly prepared prior to surgery, their anesthetic management during surgery will always be less than satisfactory. Preparation consists of correcting underlying pulmonary pathology insofar as possible and of eliminating factors that may increase the possibility of postoperative respiratory complications. Extrapulmonary causes of decreased ventilation must be sought out, for they are often reversible. Pleural or ascitic fluid should be removed by paracentesis, and obesity must be eliminated by an enforced program of weight reduction.

Respiratory infections must be controlled. In the upper respiratory tract, control includes treatment of chronic sinusitis and avoidance of elective surgery during acute infections, such as the common cold. In infections of the lower part of the respiratory tract, antibiotics should be administered parenterally and by inhalation of nebulized solutions if necessary. Adequate drainage of purulent secretions from bronchiectasis or lung abscesses must be assured by the use of pulmonary detergents, postural drainage, and bronchoscopic aspiration when such treatment is indicated. Patients with bronchiectasis should be operated on only after they have been able to spend several hours in the morning coughing and raising their own secretions. Actual or potential obstruction of the respiratory passages must be corrected. Patients with asthma should be desensitized to the offending allergen if possible and treated, if necessary, with cortisone and bronchodilating drugs.

Severe emphysema represents a serious and increasingly frequent complication. Because alveolar ventilation is inadequate to remove carbon dioxide, patients with emphysema have varying degrees of respiratory acidosis. Pulmonary infection may be superimposed. There may also be increased resistance to blood flow through the lungs, resulting in cor pulmonale with right-sided heart failure. Preoperatively, any myocardial decompensation is an indication for digitalization in these patients. Any infection is an indication for antibiotic therapy.

A potent carbonic anhydrase inhibitor, acetazolamide (Diamox), may be used preoperatively to decrease the respiratory acidosis. By interfering with normal renal electrolyte excretion, acetazolamide produces a bicarbonate diuresis. The resultant fall in plasma bicarbonate level is associated with a decrease in plasma pH and a lowering of abnormally high car-

bon dioxide tensions. The exact mechanism by which acetazolamide improves alveolar ventilation remains incompletely defined, but the reduction in carbon dioxide tension may mount to 10 to 15 mm. Hg.[1] Although the beneficial effects of prophylactic administration of acetazolamide remain to be quantitated, its use in patients with severe emphysema who can be offered little else appears justified. It is especially appropriate in emphysematous patients about to undergo major upper abdominal surgery, for these are the patients whose respiratory exchange is most altered postoperatively. Acetazolamide, 250 to 750 mg. per day, may be given in one dose or two divided doses for four or five days preoperatively. It should be replaced by ammonium chloride on the day before surgery, so that the metabolic acidosis created by the acetazolamide may be lessened on the day of surgery.

Preanesthetic Medication.—Appropriate preanesthetic medication is of fundamental importance in the safe anesthetic management of patients with respiratory disease. Parasympatholytic drugs should be used in amounts somewhat in excess of the normal to reduce otherwise copious and troublesome secretions. Preanesthetic sedation should be obtained with drugs that not only produce a sense of mental relaxation and detachment but also do so without impairing ventilation. In carefully controlled studies, Lasagna and others[2] have shown that narcotics are far less satisfactory and predictable producers of euphoria than are barbiturates. For this reason alone barbiturates are preferable to analgesics for preanesthetic medication.

Also, Eckenhoff and others[3] have demonstrated that all commonly used analgesics depress respiration when given in therapeutic amounts to normal patients. Depression occurs to the extent that carbon dioxide tensions are invariably elevated, but it does not occur after hypnotic doses of barbiturates. In patients already suffering from an inability to excrete carbon dioxide normally, the use of analgesics for premedication is ill-advised unless the patient has pain. Preexisting respiratory inadequacy will not only be accentuated by analgesics but also the desired sedation will not be as predictably attained as with the use of barbiturates.

Management During Anesthesia

Choice of Anesthetic Agent and Technique.—Before consideration is given to the pharmacological and physiological properties of anesthetics as they affect patients with respiratory disease, three rather negative but nonetheless fundamental principles should be emphasized. The first principle is that none of the presently available anesthetic agents or techniques is ideal. They all have their advantages as well as their disadvantages. For patients with respiratory disease, the most satisfactory agent will be the one that provides advantages outweighing disadvantages, so that the over-all risk to the patient, although of necessity not eliminated, is diminished.

Secondly, anesthetic agents per se have no influence on the incidence of postoperative respiratory complications. For example, inguinal herniorrhaphies performed with the patient under spinal or local anesthesia are followed by respiratory complications with the same frequency as those performed with the patient under ether anesthesia.[4] Site of surgery, age, sex, body build, and, as Dripps and Deming[5] so aptly demonstrated, the care and ability with which the anesthesia is administered are all factors that do influence the development of postoperative respiratory complications. The anesthetic itself does not. Thirdly, although preexisting pulmonary infections (e. g., tuberculosis) are adversely affected by anesthesia and surgery, the degree to which they are influenced is not related to the particular general anesthetic agent used.[6] The pharmacological and physiological effects of anesthetics on the respiratory system can be discussed only with these three basic concepts in mind. They are prerequisite to an objective and scientific approach to the problem.

Use of Ether: Ether, the most potent inhalation anesthetic commonly used today, can be administered with a concentration of oxygen higher than can be used with any other agent. Surgical anesthesia with muscular relaxation is maintained with 4% ether and 96% oxygen in the inspired air. This high concentration of oxygen may prove advantageous in certain patients with severe pulmonary disease. Ether is also the only general anesthetic that, when given in concentrations adequate for moderate or light planes of surgical anesthesia, does not invariably cause depression of respiration to the point where respiratory acidosis supervenes.[7] Alveolar ventilation may actually be increased by ether, except in the deeper planes of anesthesia.

Respiratory acidosis can and most certainly does occur during the administration of ether, but it is neither as frequent nor as severe as that present with equal depths of anesthesia obtained with other agents. In patients with respiratory disease, this is a significant advantage. When and if respiratory acidosis does occur under light ether anesthesia, its presence may be, and usually is, clinically detected by alterations in the respiratory pattern. The sensitivity of the respiratory center to elevations in carbon dioxide level is depressed by higher concentrations of ether,[8] but during light anesthesia this depression is not severe enough to prevent completely the hyperventilation of respiratory acidosis. Simple and reliable objective methods of rapidly determining alveolar carbon dioxide tensions under clinical conditions are not available. The ability to recognize clinically and so to treat respiratory acidosis during moderate or light ether anesthesia is an invaluable aid in managing patients with respiratory disease.

The major disadvantage of ether as a general anesthetic in patients with respiratory disease is that recovery may be prolonged. Prolonged recovery occurs most frequently after long operations, in patients with emphysema, and after the administration of ether by the inexperienced. Recovery from ether anesthesia is not, however, accompanied by the same respiratory depression that follows recovery from equal depths of anesthesia produced by other general anesthetic agents. During the period of recovery from ether anesthesia there may be an increased production of mucus, but, as already indicated, this does not add to the is a matter for serious consideration in this day of increasingly complex anesthetic techniques. Since both methods are, however, satisfactory when correctly employed, the decision of which to use will usually depend upon the philosophy and training of the anesthetist and the financial resources of the hospital. From a practical point of view, at the present time it is more important to spend time, effort, and energy emphasizing the necessity of adequate ventilation and how it may be manually attained rather than to change anesthetists into mechanics versed in the mechanical problems and idiosyncrasies of various pumps, valves, and flywheels. It is economically certainly more feasible. The ultimate welfare of the patient will also be increased.

There is only one situation in which use of certain types of mechanical respirators has distinct advantages over manually performed ventilation. That situation occurs in patients with decreased cardiac output. During inspiration there normally exists a negative intrathoracic pressure that aids in venous filling of the right side of the heart. This pressure is eliminated by methods of artificial ventilation devoid of any negative phase and consisting solely of intermittent positive pressure. Patients whose cardiovascular status is precarious may react adversely to such positive pressures by showing further falls in cardiac output and blood pressure.[14] Since manual control of respiration eliminates negative pressures throughout the respiratory cycle, a mechanical ventilator providing negative pressure during expiration should be employed in such patients.

Postoperative Management

Immediate Postoperative Period.—The immediate postoperative period is as critical for a patient with respiratory disease as the operative period. The importance of competent supervision in a postanesthetic recovery room staffed by specially trained personnel cannot be overemphasized. Attention is centered on the prevention or correction of any interference with adequate respiration. Depression of the respiratory center caused by analgesics given during surgery is to be counteracted by use of specific antagonists such as nalorphine hydrochloride or levallorphan (*p*-3-hydroxy-N-allylmorhinan) tartrate. If caused by barbiturates or inhalation anesthetics, respiratory depression must be compensated for by artificial ventilation until such time as the respiratory center regains its normal threshold.

Any inefficiency of the muscles of respiration due to muscle relaxants must similarly be compensated for by artificial respiration. Muscle relaxant antagonists such as edrophonium (Tensilon) chloride are not to be wholly relied upon, for, although they may be temporarily effective, their effects may wear off before normal muscle activity returns. The fundamental danger of respiratory obstruction caused by soft tissues, secretions, or vomitus must be constantly guarded against. Obstruction is still one of the foremost preventable causes of death in the immediate postoperative period. Administration of oxygen should be employed unhesitatingly. Carbon dioxide inhalation is unnecessary in the immediate postoperative period. Excessive carbon dioxide levels are often already present, especially in the patient with respiratory disease. Addition of further carbon dioxide may make matters worse.

Management in the Ward.—After the immediate postoperative period has passed and the patient has returned to the ward, the respiratory cripple still has many dangers to overcome. Prophylactic administration of antibiotics is often indicated in these patients. Repeated, thorough physical examinations of the chest should be performed, including x-rays when necessary. Patchy areas of atelectasis should be treated by forced coughing and hyperventilation, by frequent changes of position and by early ambulation. Larger areas of atelectasis are an indication for immediate bronchoscopy. Because of their action as respiratory depressants, analgesics should be used sparingly and only for the relief of pain, not as sedatives. After certain types of surgery, nerve blocks may be effective in relieving pain, thus avoiding the use of analgesics. If such blocks are utilized, they must be performed at frequent intervals with relatively short-acting local anesthetics of known safety. At the present time no safe local anesthetics are available that will provide anesthesia for more than a matter of hours.

The performance of a tracheotomy at the conclusion of surgery may add greatly to the safe postoperative recovery of selected patients with pulmonary disease. When the patient is unable to raise his own secretions either because they are so profuse or because he is so weak, a prophylactic tracheotomy may prove lifesaving. This procedure will also decrease respiratory dead space by as much as one-third or even one-half of its normal 150 cc. Reducing dead space by 50 cc. in an emphysematous patient with a fixed tidal volume of 300 cc. will increase the amount of inspired air available for alveolar ventilation by about 30%. As important as the decision to do a tracheotomy, however, is the quality of care devoted to the tracheotomy after it has been performed. Suction through a tracheotomy must be done aseptically, gently, and rapidly. If suction is not correctly performed, hypoxia ensues, tissues are traumatized, and secretions increased.[15] Special equipment is necessary to deliver high concentrations of humidified oxygen to a tracheotomy. Insertion of a nasal catheter through the tracheotomy tube is to be condemned. Routine tracheotomy care is not to be delegated to the routinely trained. It requires special instruction and meticulous attention.

Summary

Safe anesthesia for patients with respiratory disease depends upon careful evaluation of each individual case. The management will vary according to the type and severity of the pulmonary pathology, the site and nature of the proposed surgery, the pharmacological effects of the anesthetic agent, and the skill of the person administering the anesthetic.

IMMUNIZATION OF INFANTS WITH LIVING ATTENUATED POLIOMYELITIS VIRUS

LABORATORY INVESTIGATIONS OF ALIMENTARY INFECTION AND ANTIBODY RESPONSE IN INFANTS UNDER SIX MONTHS OF AGE WITH CONGENITALLY ACQUIRED ANTIBODIES

Hilary Koprowski, M.D., Thomas W. Norton, Pearl River, N. Y., Klaus Hummeler, M.D.

and
George A. Jervis, M.D., Thiells, N. Y.

• Two types of living attenuated poliomyelitis virus were administered by mouth to 24 bottle-fed infants by adding the virus preparations to the formula. Sixteen received the SM strain (representing type 1), two received the TN strain (type 2), and six received both strains at different times. Ingestion of SM was followed promptly by an asymptomatic alimentary infection, demonstrated by isolating the virus from the feces. Repeated doses were necessary to establish the carrier state in three of these infants Ingestion of TN by two infants was followed similarly by the isolation of type 2 virus from the feces. All infants developed active immunity after the inapparent alimentary infection It was found safe to administer the virus to infants less than a month old. Two infants who had not received the virus were placed in cribs between those of other infants carrying SM but did not contract the infection The presence of homotypic antibodies congenitally acquired from the mother did not prevent an active response in infants who received an adequate amount of virus.

In the course of studies conducted during the past six years, approximately 500 individuals have received by the oral route the SM (type 1) and TN (type 2) attenuated strains of poliomyelitis virus. The largest group of recipients comprised children from 3 to 12 years of age who had no demonstrable antibodies to the type of virus being administered. In one instance, the TN strain was given to a 3-month-old baby who showed the presence of type 2 antibodies probably acquired from her mother. (No blood sample was obtained from this mother for antibody determinations.) This infant became an intestinal carrier after the oral administration of the virus and developed a high titer of neutralizing antibodies 28 days after the feeding of virus.[1] Thus, here was an example that congenital passive immunity did not interfere with multiplication of the virus in the alimentary tract or with the subsequent development of active immunity Further studies undertaken along similar lines indicated that immune serum globulin (human) administered simultaneously with the attenuated viruses (types 1 and 2) did not prevent intestinal carriage of virus or have any deleterious effect on the antibody response [2] These findings led to the present trial with infants under 6 months of age, most of whom had circulating antibodies derived from their mothers against the type of virus being fed. Clinical data have been presented elsewhere.[3]

Material and Methods

Strains of Virus.—The history and properties of the TN (type 2) and SM (type 1) strains have been described fully in extensive reports published elsewhere [2] and will not be repeated here.

Administration of Virus.—SM virus-infected tissue culture fluid, either undiluted or as a 1:100 dilution in saline solution, was mixed in equal parts with glycerin. The TN virus, in the form of a 20% suspension of mouse brain and cord, was also mixed with glycerin

---

From the Viral and Rickettsial Section, Research Division, Lederle Laboratories, American Cyanamid Company (Dr Koprowski and Mr. Norton), School of Medicine, University of Pennsylvania, and Children's Hospital (Drs Hummeler and Stokes), Hunterdon County Medical Center (Dr Hunt), Medical Department, Clinton Farms (Dr Flack), and Research Department, New York State Department of Mental Hygiene, Letchworth Village (Dr Jervis) is a matter for serious consideration in this day of increasingly complex anesthetic techniques. Since both methods are, however, satisfactory when correctly employed, the decision of which to use will usually depend upon the philosophy and training of the anesthetist and the financial resources of the hospital. From a practical point of view, at the present time it is more important to spend time, effort, and energy emphasizing the necessity of adequate ventilation and how it may be manually attained rather than to change anesthetists into mechanics versed in the mechanical problems and idiosyncrasies of various pumps, valves, and flywheels. It is economically certainly more feasible. The ultimate welfare of the patient will also be increased.

There is only one situation in which use of certain types of mechanical respirators has distinct advantages over manually performed ventilation. That situation occurs in patients with decreased cardiac output. During inspiration there normally exists a negative intrathoracic pressure that aids in venous filling of the right side of the heart. This pressure is eliminated by methods of artificial ventilation devoid of any negative phase and consisting solely of intermittent positive pressure. Patients whose cardiovascular status is precarious may react adversely to such positive pressures by showing further falls in cardiac output and blood pressure.[14] Since manual control of respiration eliminates negative pressures throughout the respiratory cycle, a mechanical ventilator providing negative pressure during expiration should be employed in such patients.

Postoperative Management

Immediate Postoperative Period.—The immediate postoperative period is as critical for a patient with respiratory disease as the operative period. The importance of competent supervision in a postanesthetic recovery room staffed by specially trained personnel cannot be overemphasized. Attention is centered on the prevention or correction of any interference with adequate respiration. Depression of the respiratory center caused by analgesics given during surgery is to be counteracted by use of specific antagonists such as nalorphine hydrochloride or levallorphan (*p*-3-hydroxy-N-allylmorhinan) tartrate. If caused by barbiturates or inhalation anesthetics, respiratory depression must be compensated for by artificial ventilation until such time as the respiratory center regains its normal threshold.

Any inefficiency of the muscles of respiration due to muscle relaxants must similarly be compensated for by artificial respiration. Muscle relaxant antagonists such as edrophonium (Tensilon) chloride are not to be wholly relied upon, for, although they may be temporarily effective, their effects may wear off before normal muscle activity returns. The fundamental danger of respiratory obstruction caused by soft tissues, secretions, or vomitus must be constantly guarded against. Obstruction is still one of the foremost preventable causes of death in the immediate postoperative period. Administration of oxygen should be employed unhesitatingly. Carbon dioxide inhalation is unnecessary in the immediate postoperative period. Excessive carbon dioxide levels are often already present, especially in the patient with respiratory disease. Addition of further carbon dioxide may make matters worse.

Management in the Ward.—After the immediate postoperative period has passed and the patient has returned to the ward, the respiratory cripple still has many dangers to overcome. Prophylactic administration of antibiotics is often indicated in these patients. Repeated, thorough physical examinations of the chest should be performed, including x-rays when necessary. Patchy areas of atelectasis should be treated by forced coughing and hyperventilation, by frequent changes of position and by early ambulation. Larger areas of atelectasis are an indication for immediate bronchoscopy. Because of their action as respiratory depressants, analgesics should be used sparingly and only for the relief of pain, not as sedatives. After certain types of surgery, nerve blocks may be effective in relieving pain, thus avoiding the use of analgesics. If such blocks are utilized, they must be performed at frequent intervals with relatively short-acting local anesthetics of known safety. At the present time no safe local anesthetics are available that will provide anesthesia for more than a matter of hours.

The performance of a tracheotomy at the conclusion of surgery may add greatly to the safe postoperative recovery of selected patients with pulmonary disease. When the patient is unable to raise his own secretions either because they are so profuse or because he is so weak, a prophylactic tracheotomy may prove lifesaving. This procedure will also decrease respiratory dead space by as much as one-third or even one-half of its normal 150 cc. Reducing dead space by 50 cc. in an emphysematous patient with a fixed tidal volume of 300 cc. will increase the amount of inspired air available for alveolar ventilation by about 30%. As important as the decision to do a tracheotomy, however, is the quality of care devoted to the tracheotomy after it has been performed. Suction through a tracheotomy must be done aseptically, gently, and rapidly. If suction is not correctly performed, hypoxia ensues, tissues are traumatized, and secretions increased.[15] Special equipment is necessary to deliver high concentrations of humidified oxygen to a tracheotomy. Insertion of a nasal catheter through the tracheotomy tube is to be condemned. Routine tracheotomy care is not to be delegated to the routinely trained. It requires special instruction and meticulous attention.

Summary

Safe anesthesia for patients with respiratory disease depends upon careful evaluation of each individual case. The management will vary according to the type and severity of the pulmonary pathology, the site and nature of the proposed surgery, the pharmacological effects of the anesthetic agent, and the skill of the person administering the anesthetic.

789 Howard Ave. (4).

had responded with a high titer of type 2 antibodies. Although a very low level of type 1 antibodies was observed in the maternal blood (table 1), no antibodies were detected in the infant's serum, either at birth or at the age of 119 days, when he received $10^{4.1}$ T. C. D.$_{50}$ of SM virus This feeding was followed promptly by alimentary infection with type 1 virus lasting from the 3rd to the 70th days and by a marked rise in type 1 antibodies, as determined on the 42nd and 71st days after virus administration. There was no change in the already high level of antibodies against type 2 virus, but there was a decline in the level of type 3 antibodies

The other nine infants (table 1) had not previously been fed virus, and the amount of SM virus they ingested varied from $10^{2.8}$ to $10^{5.1}$ T. C. D.$_{50}$. Alimentary infection followed each feeding, and the virus was excreted for periods ranging from 55 days (infant no. 3) to 108 days (infant no. 1). A significant rise in homotypic antibody levels was observed in all cases, early in certain infants (as in no 5) and later in others (as in no. 8).

A comparison of the figures in the last two columns with those in the sixth and seventh in table 1 indicates that there was a decrease in type 2 (except for infant no. 8) and in type 3 antibody titers during the 44 to 87 days after the feeding with the heterotypic SM virus. The difference in the case of type 3 antibody titers was greater and the decline more pronounced.

Table 2 summarizes results obtained with infants who were 175, 117, and 86 days old when given $10^{4.8}$, $10^{4.8}$, and $10^{5.5}$ T. C. D.$_{50}$, respectively, of SM virus. The mother of infant no. 14 had a low (1:6) titer of type 1 antibodies, and at the time her baby was fed type 1 virus its serum antibody titer was <1:2. The same infant had previously received type 2 (TN) virus (see table 7), but the type 2 antibody concentration in his blood was rather low (1:16). Nine days after ingestion of SM virus, the type 1 antibody titer had risen to 1:256, and it was slightly higher 31 days after virus feeding. The unusually early (9th day) homotypic antibody response may have been related to the persistence of an antigenic stimulus from the administration of the heterotypic TN virus 28 days before (see table 7). The feeding of SM virus to infant no. 16, in addition to producing a slight homotypic response on the 9th day and a pronounced response on the 31st day, also seemed to stimulate a heterotypic antibody response to type 2, as evidenced by the increase in titer from <1:2 before the administration of virus to 1:16 on the 31st day after virus was ingested. The same phenomenon was not observed with respect to antibodies against type 3 virus, which decreased, in the course of 31 days, in a pattern similar to that shown in table 1. During the 37 days after the administration of type 1 virus to infant no. 18, the homotypic antibody titer rose and the type 2 antibody level remained unchanged (1:256), while antibodies against type 3 virus declined from 1:64 to 1:4.

The duration of fecal virus excretion did not seem to be influenced by the actual level of homotypic antibodies at the time the virus was administered, which ranged from <1:2 (infants 14 and 15, tables

* T.C.D.$_{50}$ = tissue culture doses$_{50}$, expressed as logs to the base of 10.

1 and 2) to as high as 1:362 (infant 8, table 1). The concentration of type 1 virus in fecal material was determined by the titration of stool specimens in tissue culture. The results are given in table 3 for the infants reported in table 1. In order to evaluate results properly, determinations of virus content were carried out independently in two laboratories in different cities. Tissue cultures of monkey renal epithelium were used in one, and HeLa cells in the other. Comparison of values yielded by the two methods of virus titration indicated close agreement. The highest concentration of virus in stools was found within the first 16 days after feeding, confirming observations made previously with older children.[5] After the initial 16 days, the concentrations of fecal virus seemed to decrease; however, the duration and intensity of alimentary infection varied from subject to subject, with the duration ranging from 55 days (infant no. 3) to 108 days (infant no. 1).

Administration of Type 1 Virus to Infants Less than One Month Old.—Because the results obtained in the trials described above were encouraging, the "age limit" of candidates for virus ingestion was lowered to less than one month. Six infants 10 to 27 days old were given the SM strain in oral doses ranging from $10^{3.8}$ to $10^{5.5}$ T. C. D.$_{50}$ (table 4). The levels of homotypic and heterotypic antibodies before virus administration were somewhat higher than those in older infants (tables 1 and 2). Also, curiously enough, the titers of antibodies against types 1 and 2 in the cord blood of infants no. 22 and 21 were slightly higher than in the blood of their respective mothers. However, these differences may again reflect experimental errors in the neutralization tests.

With the exception of infant no. 25, the duration of alimentary infection with SM virus in this group was shorter than in the older group (tables 1 and 2). Whether this observation may be related to the high level of maternal antibodies in infants no. 21, 22, and 24 is difficult to state. It should be noted that infant no. 8 (table 1) excreted SM virus for 74 days, although the homotypic antibody titer before feeding was 1:362, i. e., slightly higher than that of infant no. 24.

There also seemed to be some relationship between the immunologic activation of the antibody system by the ingested virus and the level of antibodies acquired from the mother. An unequivocal rise in type 1 antibody titers was noted after virus feeding in the blood samples of infants no. 17, 23, and 25, whose initial antibody levels were not very high. In the remaining three infants of this group, who had high titers of type 1 antibodies at birth, response was delayed in comparison with other infants. For instance, the titer of type 1 antibody of infant no. 22 fell from 1:1,024 at birth to 1:256 37 days after virus ingestion. On the 52nd and 65th days after feeding, almost the same levels of antibody persisted. At the same time, the heterotypic antibody titers against types 2 and 3 declined. The fall of type 1 antibodies observed in blood drawn from infant no. 21 on the 37th day after virus administration was offset by a rise on the 52nd day. Finally, there was no difference in type 1 antibody titers between specimens obtained before and after the administration of virus to infant no. 24, while heterotypic antibody titers against types 2 and 3 fell.

Since, in the past, an adequate immunologic response has always followed the establishment of alimentary infection with SM virus, there is no indication

at present that infants less than one month old form an exception. The evidence of response may be slightly delayed in the youngest age group, particularly in cases where the level of congenitally acquired antibodies is very high.

Repeated Administration of Type 1 Virus.—Administration of $10^{2.8}$ T. C. D.$_{50}$ of SM virus to two infants who were 24 and 26 days old was not followed either by evidence of alimentary infection or by a rise in homotypic antibodies (no. 9 and 11, table 5). In addition, another infant 106 days old (no. 12) failed to become a carrier, and there was no rise in the level of type 1 antibodies after the administration of one drop of SM virus in 4 ml. of formula. The concentration of virus in the mixture was lower than the equivalent of $10^{2.3}$ T. C. D.$_{50}$.

To determine whether immunization failure was directly related to the small amount of virus in the ingesta, these three infants were given another virus feeding (table 5). This time no. 11 and 12 received $10^{4.1}$ T. C. D.$_{50}$ of virus, whereas the dose for no. 9 was kept low ($10^{2.8}$ T. C. D.$_{50}$). Subjects no. 11 and 12 promptly became intestinal carriers, and a marked rise in circulating type 1 antibodies followed. Infant no. 9 again failed to become an alimentary carrier, and his level of type 1 antibodies remained unchanged for 42 days. Finally, after a third feeding consisting of $10^{4.3}$ T. C. D.$_{50}$ of virus, both alimentary infection and a rise in homotypic antibodies were achieved.

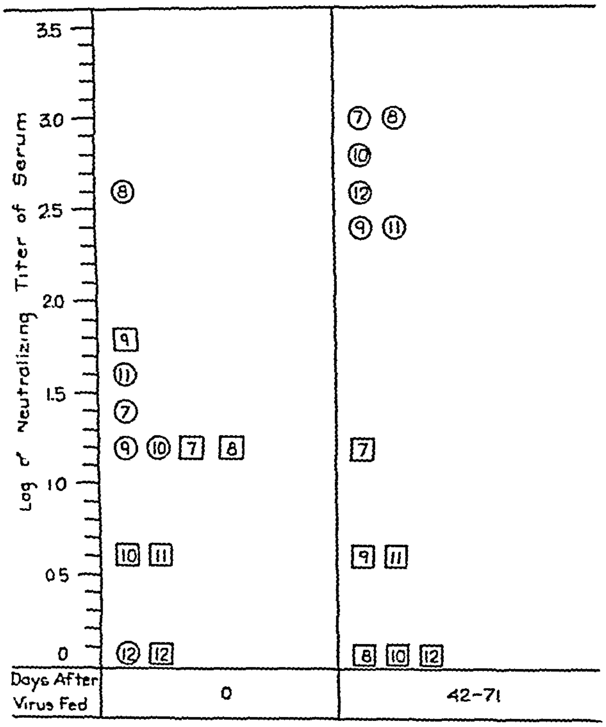

Fig. 1.—Increase of homologous antibodies after feeding type 1 with no simultaneous increase of type 3 antibodies. Numbers in circles, number of subject with antibodies against type 1; numbers in squares, number of subject with antibodies against type 3. Ages in months of infants at date of feeding were 1 (no. 8), 2 (no. 10 and 11), 2½ (no. 7), 3½ (no. 9), and 5 (no. 12).

Although these data are of meager statistical value, neither the age of the infants nor antibody status at the time of virus administration appeared to be responsible for the three "immunization failures." The roles of the relatively small amount of virus ingested and of some other possibly preexisting factor that may have prevented the virus from reaching a multiplication site in the intestinal tract may have to be considered (see Comment, below).

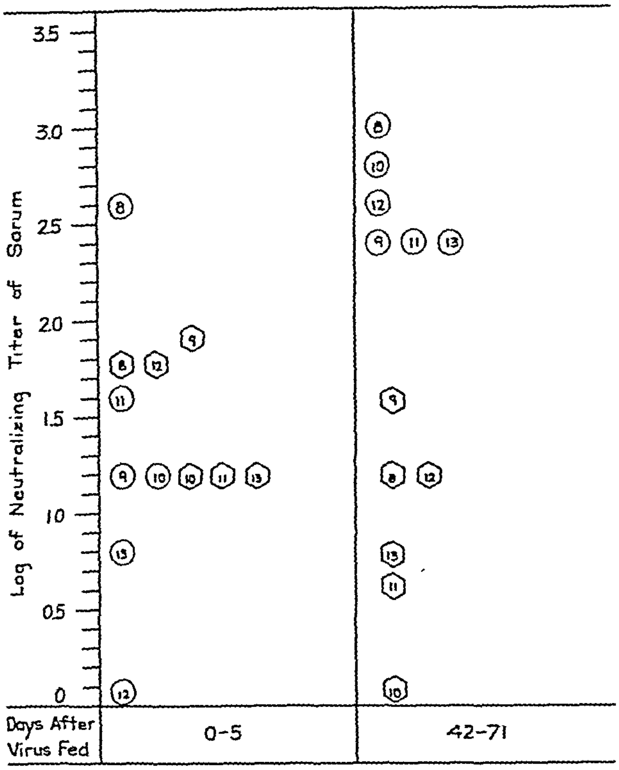

Fig. 2.—Increase of homologous antibodies after feeding type 1 with simultaneous decrease of type 2 antibodies. Numbers in circles, number of subject with antibodies to type 1; numbers in hexagons, number of subject with antibodies to type 2. Ages in months of infants at date of feeding were 1 (no. 8), 2 (no. 10, 11, and 13), 3½ (no. 9), and 5 (no. 12).

Fate of Homotypic and Heterotypic Antibodies.—The antibody titers in the serums of seven infants who received the type 1 virus are presented diagrammatically in figure 1 (infants no. 7-12) and figure 2 (infants no. 8-13). The clinical histories of these infants have been summarized in the preceding section of this report.

Figure 1 shows that after the administration of SM virus there was a marked rise in homotypic antibody titers. The rise was least significant in infant no. 8, whose serum showed a high level of congenital antibodies before the administration of virus. Within the observation period (42-71 days) antibodies against type 3 virus declined or remained the same.

Data on type 2 antibodies are presented in figure 2. In this case, the rise in homotypic antibody level was not accompanied by as marked a drop in type 2 as in type 3 antibody titers (see fig. 1). The serum antibody titer of infant no. 10 against type 2 virus fell to zero, while the decreases in the remaining serums were not of the same magnitude.

Lack of Contagiousness of SM Virus.—In clinical trials described elsewhere,[2] transmission of fecal SM virus occurred in very few cases and only after a rather initimate contact between "donors" and "recipients." The same question was investigated on a smaller scale under the conditions of the present study.

1 and 2) to as high as 1:362 (infant 8, table 1). The concentration of type 1 virus in fecal material was determined by the titration of stool specimens in tissue culture. The results are given in table 3 for the infants reported in table 1. In order to evaluate results properly, determinations of virus content were carried out independently in two laboratories in different cities. Tissue cultures of monkey renal epithelium were used in one, and HeLa cells in the other. Comparison of values yielded by the two methods of virus titration indicated close agreement. The highest concentration of virus in stools was found within the first 16 days after feeding, confirming observations made previously with older children.[5] After the initial 16 days, the concentrations of fecal virus seemed to decrease; however, the duration and intensity of alimentary infection varied from subject to subject, with the duration ranging from 55 days (infant no. 3) to 108 days (infant no. 1).

Administration of Type 1 Virus to Infants Less than One Month Old.—Because the results obtained in the trials described above were encouraging, the "age limit" of candidates for virus ingestion was lowered to less than one month. Six infants 10 to 27 days old were given the SM strain in oral doses ranging from $10^{3.8}$ to $10^{5.5}$ T. C. D.$_{50}$ (table 4). The levels of homotypic and heterotypic antibodies before virus administration were somewhat higher than those in older infants (tables 1 and 2). Also, curiously enough, the titers of antibodies against types 1 and 2 in the cord blood of infants no. 22 and 21 were slightly higher than in the blood of their respective mothers. However, these differences may again reflect experimental errors in the neutralization tests.

With the exception of infant no. 25, the duration of alimentary infection with SM virus in this group was shorter than in the older group (tables 1 and 2). Whether this observation may be related to the high level of maternal antibodies in infants no. 21, 22, and 24 is difficult to state. It should be noted that infant no. 8 (table 1) excreted SM virus for 74 days, although the homotypic antibody titer before feeding was 1:362, i. e., slightly higher than that of infant no. 24.

There also seemed to be some relationship between the immunologic activation of the antibody system by the ingested virus and the level of antibodies acquired from the mother. An unequivocal rise in type 1 antibody titers was noted after virus feeding in the blood samples of infants no. 17, 23, and 25, whose initial antibody levels were not very high. In the remaining three infants of this group, who had high titers of type 1 antibodies at birth, response was delayed in comparison with other infants. For instance, the titer of type 1 antibody of infant no. 22 fell from 1:1,024 at birth to 1:256 37 days after virus ingestion. On the 52nd and 65th days after feeding, almost the same levels of antibody persisted. At the same time, the heterotypic antibody titers against types 2 and 3 declined. The fall of type 1 antibodies observed in blood drawn from infant no. 21 on the 37th day after virus administration was offset by a rise on the 52nd day. Finally, there was no difference in type 1 antibody titers between specimens obtained before and after the administration of virus to infant no. 24, while heterotypic antibody titers against types 2 and 3 fell.

Since, in the past, an adequate immunologic response has always followed the establishment of alimentary infection with SM virus, there is no indication

no. 15, 19, and 20. Thus, one may assume that an immunologic response to TN virus occurred in infants no. 15 and 20 and probably in the other two infants. Determination of antibodies after a longer interval may dispel any doubts on this point.

Persistence of Immunity.—Serum samples were secured from five infants seven months and from one four months after the administration of type 1 virus (table 8). With two exceptions, no. 1 and 13, the same subjects also received TN (type 2) virus at the ages shown in table 8.

Data in the last three columns of table 8 indicate that feeding of type 1 virus was obviously responsible for the persistence of a high level of homotypic antibodies throughout the four-to-seven-month observation period. This is fully substantiated by the fact that during the same interval the type 3 antibody titers (last column, table 8) in every case except one dropped to <1:2. The point is even more clearly illustrated in figure 3, in which the rise in type 1 antibodies of five infants is contrasted with the simultaneous decrease or lack of increase in heterotypic type 3 antibodies.

After the administration of TN virus, there was a slight rise of type 2 antibody titer in infant no. 4 and a considerable rise in infant no. 3, whereas, during the five-month observation period, type 2 antibodies declined in the blood of infants no. 5. After an initial drop, there was a slight increase in the levels of type 2 antibodies in infants no. 1 and 13, who had received type 1 virus alone seven and four months previously. This may represent a remnant of heterotypic response to the type 1 feeding (see table 1), or it may indicate possible exposure to type 2 virus. However, no attempt was made to isolate fecal virus after the excretion of type 1 virus ceased, and no definite statement can be made. Clinical follow-up of these infants revealed normal development.

Comment

The results obtained in this study have shown that a single administration by the oral route of attenuated poliomyelitis virus to infants less than 6 months old will elicit alimentary infection and will activate an immunologic response, irrespective of the presence of passively transferred serum antibodies to the virus fed. Virus was fed to 24 infants; 16 received the SM (type 1) virus alone, 2 received the TN (type 2) virus, and 6 received both viruses administered weeks or months apart. Careful pediatric and nursing care of the infants failed to reveal objective signs of any ill-effects attributable to the ingestion of poliomyelitis virus. All of the infants who received the viruses at different ages showed gain in weight comparable to infants who were not fed virus.

Ingestion of type 1 virus was followed by prompt establishment of alimentary infection. That tissues of an infant 10 days old are able to support growth of poliomyelitis virus is not surprising per se, since cases of poliomyelitis infection with virulent virus have been described in infants shortly after birth after possible intrauterine infection.[6] A number of cases of poliomyelitis in infants less than a year old have also been reported in medical literature.[7]

Intestinal mucosa of children 6 to 15 years old previously has been found to be susceptible to direct infection with two plaque-forming particles of SM virus administered in a capsule.[2] This method of virus administration could not be applied in the present study, and virus feeding in liquid form was substituted. The results, though few in number, suggest that the inoculum had to exceed considerably two plaque-forming particles of virus in order to induce uniform alimentary infection in infants less than one month old. Although the number of infants fed virus at that age was too small to permit definite conclusions, SM virus in concentrations in excess of $10^{-3.0}$ T. C. D.$_{50}$ seemed to prove uniformly infectious and immunogenic.

The seemingly higher resistance of younger infants may depend upon two factors. One could be related to a specific difference in cell physiology during the first month of life. Thus, in a baby 30 days old or less, the virus-cell relationship may not be the same as that in older infants and children and may adversely affect the rate of multiplication of the virus, viz., infant no. 22 (table 4), who excreted the virus only between the 5th and 12th days after feeding. A direct relationship between age and susceptibility to poliomyelitis infection has been observed in laboratory animals,[8] and the relative infrequency of poliomyelitis infections among young infants has been noted.[7]

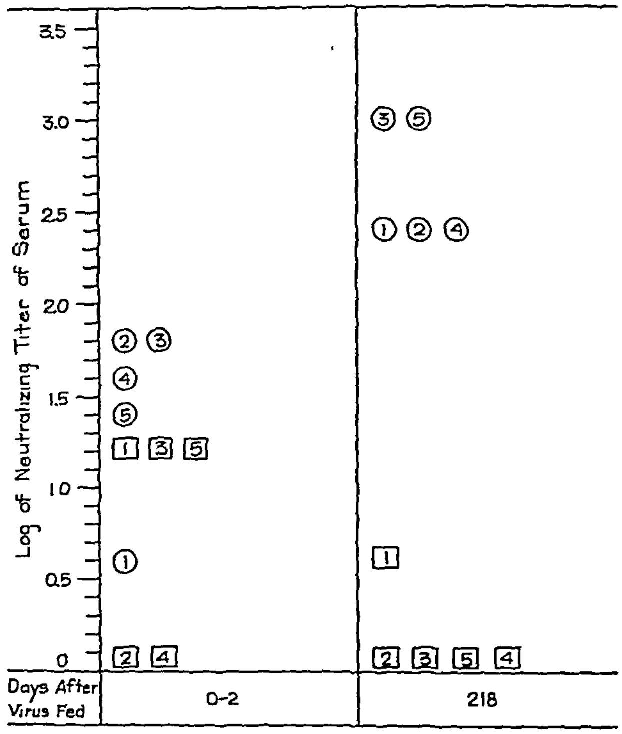

Fig. 3.—Increase of homologous antibodies after feeding type 1 with no simultaneous increase of type 3 antibodies. Numbers in circles, number of subject with antibodies to type 1; numbers in squares, number of subject with antibodies to type 3. Ages in months of infants at date of feeding were 1 (no. 1), 2 (no. 3 and 5), and 3 (no. 2 and 4).

The second factor to be considered is the amount of congenitally acquired homotypic antibodies. The concentration of these was higher in infants at the age of 30 days than in older infants and children or after administration of immune serum globulin.[2] However, in studies on passive-active immunization of primates, Bodian[9] observed that the presence of passive antibodies, even at high levels, did not interfere with the establishment and course of ailmentary infection with poliomyelitis virus but did prevent viremia and invasion of the central nervous system. In the present study, no. 22 was the only infant who had a titer of passive antibodies to type 1 as high as 1:1,000, which may be related to the short duration of SM virus excretion in his case.

Serum antibody titers of the two infants (no. 9 and 11, table 5) who failed to develop alimentary infections after the first administration of a small amount of virus or of those who showed a slightly delayed rise in antibodies after virus administration were also high in comparison with those of the remaining subjects (table 1) of the same series. From present data, it appears doubtful that in infants less than one month old a high titer of passive antibodies will consistently prevent alimentary infection with a small amount of type 1 virus. Because of the small number of subjects in this trial, it was not possible to determine what concentration of antibodies might influence the duration of alimentary infection. Whichever of the factors—relative lack of susceptible cells or high titer of serum antibodies—was in operation, feeding of adequate amounts (in excess of $10^{-3.0}$ T. C. D.$_{50}$) of SM virus resulted in inapparent infection and immune responses.

The administration of type 2 (TN) virus to eight infants led to a rise in homotypic antibody titers in the blood of five. The response of the remaining three, who received $10^{2.8}$ mouse P. D.$_{50}$ of the virus, will have to be evaluated from the results of neutralization tests to be performed on blood samples collected in the future. The two factors mentioned above (in connection with the administration of type 1 virus) conceivably may play a role in this case also, and perhaps feeding larger amounts of virus will yield more uniform results.

Changes in type 2 neutralizing antibody levels such as occurred in subjects who were infected with type 1 virus have been reported before by several investigators.[10] In the present study, among 16 infants who received the attenuated type 1 virus, type 2 antibody titers increased in five cases and the titer failed to decline in two additional cases. The heterotypic rise was maintained in the blood of two infants four and seven months after administration of type 1 virus (table 8). Similar changes did not occur in type 3 neutralizing antibodies, which were found to decline gradually and which reached levels below detection in the blood of infants at the age of 7 to 10 months. There was also no effect on the development of type 1 antibodies after administration of type 2 virus to three infants who had no preexisting type 1 antibodies. Thus, it may be concluded within the limits of these data that a response to SM virus feeding may be broader than a response solely to the type causing alimentary infection.

With the current trial included, attenuated strains of poliomyelitis virus have been given to infants, children, adolescents[11] and to adults (Sabin[12]). As far as can be judged, none of the subjects belonging to these different age groups showed any ill-effects that could be attributed to the ingestion of live virus.

For a more extensive clinical trial, the youngest age group is the most desirable, since it represents a relatively immobile population in which the possibility of transmission of the virus from one subject to another is more remote (*see* table 6). The presence of passive immunity will not prevent an active response if an adequate amount of virus is administered, and "blending" of the two types of immunity may circumvent the danger of exposure to virulent virus at an age when congenitally acquired antibodies tend to diminish or disappear. Follow-up studies over a much longer period of time[5] may indicate or give substance to the hope that the level of homotypic antibodies induced by the ingestion of virus in the first year of life may confer permanent protection.

Summary

Living attenuated poliomyelitis virus was administered by the oral route to 24 infants. Sixteen received SM (type 1) virus alone, two the TN (type 2), and six both viruses at different times. All the infants were under 6 months old; the ages of six were between 10 and 27 days. Most of them had antibodies acquired from their mothers to the virus fed. All infants developed active immunity after inapparent alimentary infection. High levels of homotypic antibodies caused by the feeding of virus were maintained during an observation period of seven months.

FETAL MORTALITY IN CESAREAN SECTION

Moses Grossman, M.D.
and
Ralph C. Benson, M.D., San Francisco

• *The gross fetal mortality associated with cesarean sections ranged from 4.5 to 15.6% in 13 institutions. The causes of death and indications for sections have been reviewed in detail for the last 16 years, covering 569 sections, at University of California Medical Center. The maternal mortality has been reduced by such factors as briefer trials of labor, blood transfusion, and new surgical techniques, but the fetal mortality has not shown corresponding improvement. Erythroblastosis, congenital anomalies, and atelectasis with its complications accounted for many deaths occurring within an hour after birth. Prematurity, however, is the largest single contributing factor to the high mortality rate. An accurate appraisal of arrival at term is important in order that a premature infant will not be delivered by ineptly timed and purely elective section.*

A striking and continued reduction has occurred in maternal morbidity and mortality after cesarean section, as a result of medical advances in the past two decades; however, fetal salvage has not improved encouragingly. With increasing safety for the mother, popularization of cesarean section logically followed. Nevertheless, when it became apparent that operative delivery from above did not necessarily insure the survival of a healthy infant, a more conservative attitude developed with regard to indications for and timing of cesarean section.

The obstetrician need not be reminded of his obligation to both mother and infant for safe delivery. The obvious risks of prematurity must be accepted, however, when an urgent maternal indication for cesarean section is present. Yet, in cases where hasty elective surgery is performed for borderline disproportion or when repeat section is done too early, the supposed term child is occasionally immature and frequently dies. As a consequence, the fate of the infant after cesarean section is of timely and vital importance. We have, therefore, reviewed the experience with cesarean section at the University of California Medical Center, San Francisco, for the past 48 years, with special consideration of the period 1940-1955, inclusive, in an attempt to answer the question, "Does cesarean section insure the delivery of a normal, living child who will survive?"

For purposes of review and comparison, the uncorrected fetal mortality in a number of large published series is summarized in table 1. The high figures are quite startling. The notable factors in this series are the high incidence of premature infants and the mortality associated with the obstetric pathology that necessitated the section, as opposed to the increased hazard of abdominal delivery. Correction for these two elements would make a comparison of fetal mortality after vaginal delivery more meaningful, but we must look to the statistics in elective sections to supply these answers. Wolff and Roter,[1] reporting on 162 elective sections where a previous cesarean was the indication, indicated a mortality of 3 (1.85%) and morbidity of 17 (10.4%).

Cesarean sections performed on clinic and private patients at the University of California Medical Center in San Francisco for the past 48 years have been reviewed (fig. 1). Our experience with respect to maternal morbidity and mortality essentially parallels that of other centers. This was reported in part previously by Arnot[2] and King.[3] The introduction of antibiotics, improved methods of anesthesia, and obstetric advances have almost eliminated maternal mortality (one maternal death since 1938—a pregnancy complicated by disseminated lupus erythematosus) and have materially reduced maternal morbidity. A striking contrast between maternal and fetal mortality, however, is shown in figure 2. As the number of deliveries and cesarean sections has increased, the absolute number of deaths in infants has steadily climbed. These data are expressed in terms of percentage of infant mortality, and figure 3 clearly indicates that (1) infant mortality in cesarean section has shown little improvement over the years and (2) the mortality is still an appreciable and serious one. It would appear, therefore, that the risk of cesarean section is still considerable if the welfare of the mother and the infant are regarded critically. A comparison of fetal loss in deliveries by cesarean section with total fetal experience over a 10-year period shows that the gross perinatal mortality of babies delivered by cesarean section was 8.3% (corrected, 2.5%); the gross infant mortality was 2.5% (corrected, 1.8%); and the gross neonatal mortality was 0.8% (corrected, 0.6%). In order to shed further light on this problem of fetal mortality, our experience at the University of California Medical Center in San Francisco is reviewed in detail from 1940 to 1955 inclusive.

Obstetric Factors

As in other centers, infants have been lost here after surgical delivery who, we now believe, might have survived. An analysis of the causative factors is revealing. The method of cesarean section, as well as the type of anesthesia, plays a part in fetal mortality and morbidity. Table 2 discloses the types of operation used during the past 16 years, together with the method of anesthesia used. A graphic representation of the type of cesarean section done at this institution during the 48-year period, 1907 through 1954, is of

genographic appraisal of fetal age, although fraught with variables and not always satisfactory, often can be of help in the timing of elective section.[4] For example, if proximal tibial and distal femoral epiphyses are not well visualized, further delay of surgery might be prudent, even though the dates themselves suggest a more advanced pregnancy. Cephalopelvic disproportion often indicates the need for surgical delivery. A trial of labor, however, should be required in borderline cases, especially when there are possible compensatory factors. Planned cesarean section prior to the onset of good labor at term has often been unnecessary and has resulted in the delivery of an immature infant. This applies also, we have found, to repeat cesarean section. A retrospective consideration of the indications for cesarean section in the 47 fatal deliveries between 1940-1955 shows that in 44 cases section was indicated from the patient's record; in 31, the timing was seemingly correct; in 9, section might have been done earlier; and in 4, section might have been postponed as baby was not at term (previous section only index used). In all fairness to the obstetricians involved, it must be admitted that a clinical situation may appear quite different in later review, particularly when only the history is available for subsequent appraisal. Nevertheless, it is our considered opinion that, in the greater interest of the child, certain of the operations probably should have been accomplished earlier and others delayed.

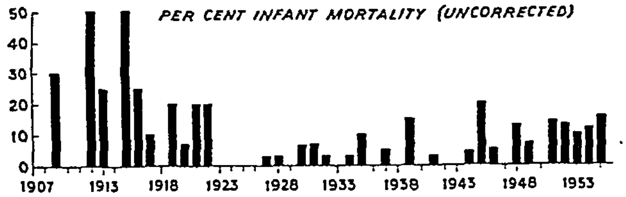

Fig. 3.—Infant mortality in cesarean sections, 1907-1955.

TABLE 3.—*Causes of Death in Twenty-seven Babies Who Lived One Hour or More (1940-1955, U. C. Medical Center)*

Anomalies of respiratory tree	1	
Nonviable (less than 800 gm.)		2
Intracranial hemorrhage		1

Fetal Factors

Over the last 16 years (1940-1955), 569 cesarean sections were performed with a total of 47 fetal deaths—a gross perinatal mortality of 8.2%. With correction for congenital anomalies incompatible with life, nonviable babies (less than 800 gm. [1.75 lb.]), erythroblastotic infants, and babies who died in utero before or during the operation, there were 15 deaths in 537 cases, or a corrected mortality of 2.9%. Of the 569 sections performed, 20 infants were either born dead or had never established respiration. Twenty-seven lived an hour or more, 16 were premature (weight under 2,500 gm. [5.5 lb.]), and 11 were full term; 20 were male and 7 female. The average length of life for the 27 babies was 2.5 days, the median being 1.7 days.

Table 3 relates the cause of death in the 27 babies who established respiration and lived an hour or more. Slightly more than half of this group died of respiratory causes, with hyaline membrane disease high on the list. This might be expected from the fact that more than one-half of these babies were premature. The six cases of erythroblastosis occurred during a one and one-half year period between 1946 and 1947, when cesarean sections were done before term (34-38 weeks) in instances where severe hemolytic disease of the newborn was suspected in the baby. This was before the use of the exchange transfusion became established. Thus, delivery by cesarean section of these babies served to superimpose prematurity onto the already existing hazard of erythroblastosis. With the use of cesarean section, our salvage of these babies was very poor and the procedure was abandoned. One of the six babies who died had hyaline membrane disease, and this, rather than erythroblastosis, was undoubtedly the cause of death. In the group of babies with congenital anomalies, it is interesting to note that both babies who died of diaphragmatic hernia were siblings, born a year apart. Of the two nonviable newborn infants, one weighed 780 gm. (1.75 lb.) and the other 450 gm. (1 lb.); the latter was, in fact, a deliberate therapeutic interruption of pregnancy. In spite of its small weight, the baby breathed and survived for 15 hours.

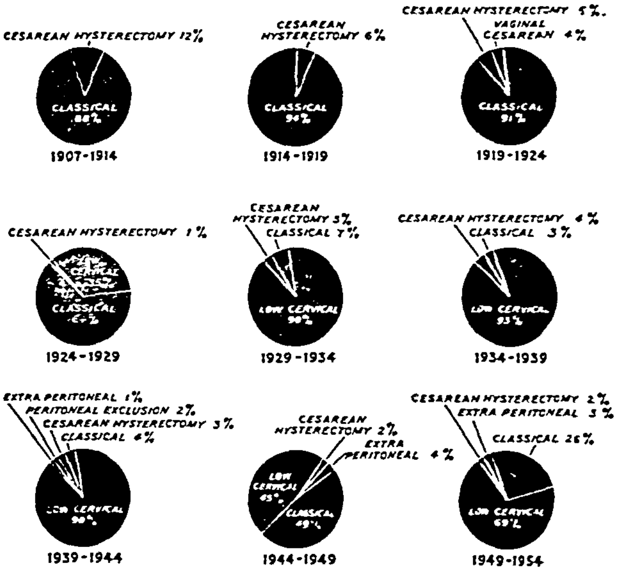

Fig. 4.—Type of cesarean section, 1907-1954.

Table 4 lists the 20 babies who did not establish satisfactory respiration. Almost all of these were born dead. There were 10 males and 10 females in this group; 9 were premature and 11 full term.

Of the 47 cesarean sections fatal to the infants, 14 were elective. The cause of death in these babies is shown in table 5. This group of babies should be considered critically in any series, because it generally excludes the serious obstetric catastrophes. Preventable deaths are apt to be found here as they were in our own series.

We have already mentioned the erythroblastotic babies in commenting on table 3. The three newborn infants who died of atelectasis, including hyaline membrane disease, were all infants who were considered to be at term, both by date and by palpation of the fetus. Cesarean section was done electively, the only indication being a previous section. At the time of delivery, all three of these babies were found to be small; two of them died of hyaline membrane disease and one of primary atelectasis. If the operative delivery had been postponed for several weeks in these cases, the outlook for survival of the babies would have been improved considerably.

TABLE 4.—*Indications for Section in Twenty Babies Who Never Established Respiration (1940-1955 University of California Medical Center)*

Baby No.	Wt. (Gm.)	Indications for Section
1	2,810	Partial premature separation of placenta
2	2,330	Obstructed labor; myoma; child dead before section
3	1,390	Severe preeclampsia
4	3,620	Prediabetic with eclampsia
5	4,800	Prediabetic with eclampsia

19	2,200	Sibling 18; achondroplast Section done early, mother suicidal
20	3,080	Severe complete premature separation of placenta; baby dead on admission to hospital

Table 6 lists the indications for cesarean section and the perinatal mortality for each indication over the last 16-year period for all cesarean sections performed. Corrections for infant mortality have been made by excluding babies who were known to be dead before the section was completed, babies who had congenital anomalies incompatible with life, and babies who were considered nonviable (less than 800 gm. [1¾ lb.]). The most common indication, by far, in this group was a previous section, and the mortality here was not a great deal higher than in the over-all obstretic experience for a comparable period.

The group with cephalopelvic disproportion was considerably smaller in our series than in most published studies from eastern teaching hospitals. This is hard to explain, although certain related factors might be a lower incidence of rickets in San Francisco and basic population differences.

As in other reported series, the group with the highest mortality was that in which premature separation of the normally implanted placenta necessitated an emergency cesarean section. The gross mortality figure of 62.5% for this group is more representative of what takes place than the corrected figure of 12.5%. The correction represents the eight babies who died of the separation before they could be delivered, the cause of death being the separation itself. In our experience, it would be more fair to state that, where serious separation of the placenta had occurred, the mortality was approximately 60%. Another group with high fetal loss was that in which cesarean section was performed because of toxemia and hypertensive disorders, but, in these cases, the maternal indication for delivery was most pressing.

TABLE 5.—*Causes of Death of Fourteen Infants Delivered by Elective Cesarean Section (1940-1955, University of California Medical Center)*

Erythroblastosis fetalis	5
Atelectasis, including hyaline membrane (these infants weighed 1,980, 2,200, and 2,800 gm.)	3
Polyhydramnios	1
Monstrosity	1
Nonviable fetus (450 gm.: late therapeutic abortion)	1
Diaphragmatic hernia	1
Baby dead in utero, previous cesarean section	2

Comment

Examination of infant perinatal and neonatal mortality rates in the United States over the past 50 years discloses the fact that today most infants are lost in the first three days of life. Bundesen[5] has stated that in the United States more infants now die in the first three days of life than during the remaining 362 days of the first year. He quotes the special committee on infant mortality of the Medical Society of the County of New York as stating that "The persistently high perinatal mortality rates stand foremost among the urgent problems on the agenda of Public Health workers." We would add to this: "and of obstetricians and pediatricians."

TABLE 6.—*Cesarean Section Indication and Total Infant Deaths (1940-1955, University of California Medical Center)*

Indication	Total No.	Gross		Corrected

Other	45	3	6.6	1	2.2

In examining the causes for the high perinatal mortality and, specifically, the reasons for no decline in recent years, one must focus attention particularly on the special groups of babies who contribute to this loss. Foremost among these are the premature infants, but another important group is that which has been examined in the preceding tables, i.e., the babies born by cesarean section. Their gross perinatal mortality of 8.2% is more than three times that of the gross infant mortality of all groups. The two outstanding causes for this high mortality are (1) prematurity and (2) depression of the fetal respiratory center brought on by hypoxia or toxic states of the mother.

Prematurity is frequently unavoidable. The situation is often one of obstetric catastrophe, such as abruptio placentae with supervening massive hemorrhage, which necessitates immediate delivery—preferably by section. Thus, the baby arrives quite prematurely, sometimes before it is viable, or at the state of maturity where the chances for survival today are not much more than 50%. However, among this group of "unavoidable prematures," one must recognize a smaller category but, nevertheless, one about which something can be done—namely, those who, through an error in dates and misjudgment of fetal weight and maturity, are delivered prematurely by elective section (three in our series). The loss of these babies, in a situation where prematurity plays an important role in their death, is truly an avoidable tragedy. One of the sad obstetric realities is that we are, as yet, ignorant about the causes of the onset of labor. It is difficult, moreover, to know when a woman has arrived at term. We believe it is better to allow the woman to go into labor, in most instances, and to perform the operation as soon as true labor starts. The pediatrician can contribute expert postdelivery care to the premature infant, but this is not nearly as promising as the reduction of the loss of these babies by the avoidance of prematurity itself.

The second great cause of increased mortality in this group is hypoxia. This was certainly a critical factor in most of our stillborn babies Enumeration of mortality statistics and causes of death does not reveal the entire picture in this regard. We have not been able to include the morbidity of the group in this series, which would be of great interest in itself. Besides the babies who were lost, there were those who suffered irreversible damage, others had atelectasis and hyaline membrane disease and survived only after a stormy, prolonged course in the nursery.

Premature separation of the placenta and placenta previa are prominent causes of fetal mortality in this group. The considerable loss of babies of preeclamptic and eclamptic mothers suggests that the state of the mother may well have had something to do with depressing the baby. There is no question but that a good regional anesthesia, limitation of heavy analgesia, avoidance of oxygen lack before and during the cesarean section, together with proper timing so as not to allow a long period of intrauterine hypoxia before the section is performed, are all important factors in reducing the fetal loss in this group.

The pediatrician can help immeasurably by recognizing the true nature of the problem. Lavage of the stomach, gentle handling, expert resuscitation, a patent airway, and the delivery of oxygen into the infant's lungs by the least traumatic means possible will all increase the salvage of the jeopardized babies.

Summary and Conclusions

Examination of infant mortality associated with deliveries by cesarean section over the last 48-year period at the University of California Hospital revealed that 569 sections were performed, with a total of 47 fetal deaths and a gross perinatal mortality of 8 2%. Allowance for congenital anomalies incompatible with life, known nonviable babies, erythroblastotic infants, and infants who were known to have died in utero before or during the operation corrects the mortality to 2 9%.

Detailed review of causes of death for the 16-year period from 1940 through 1955 revealed that prematurity is the largest single contributory factor to the high mortality rate. Fetal hypoxia, due to interference with placental circulation, and the toxic state of the mother are other leading causes of death and morbidity. While appraisal of the woman's arrival at term is difficult, this decision is extremely important so that a premature baby will not be delivered by an ineptly timed, purely elective section. On the other hand, where an obstetric emergency produces a critical intrauterine oxygen deficiency, rapid delivery, often by cesarean section, is equally important in augmenting fetal salvage.

Treatment of Obesity.—There was a considerable increase in weight loss in most of the patients receiving the Biphetamine capsule medication Over 70% of the patients taking Biphetamine lost three to four pounds and more in the three week interval, in contrast to about 85% of the patients previously on amphetamine tablets who lost less than three to four pounds during three weeks of therapy. In addition to the superior effect of the Biphetamine, this single dosage form of medication was more convenient than tablet therapy. It avoided the accidental failure to take a tablet or the unconscious avoidance of it. However, most patients will take a capsule in the morning, since their intentions are usually good at this time, and thereafter they are released from the responsibility of the need to take further medication. In addition, the therapeutic effect is smoother because of the elimination of the sharp rises and declines in blood levels, and it is thus more effective in alleviating hunger. . . . Suppression of appetite and loss of weight after administration of one capsule of this material are superior to the results obtained with an even greater dose of amphetamine in tablet form. Side-reactions with the amphetamine-resin complex are somewhat less than with tablet therapy. . . . . The amphetamine-resin complex fulfills a need for a product which releases the drug on a predictable basis for a period of 10 to 14 hours.—S. C. Freed, M D, J. W. Keating, B.S., and E. E. Hays, Ph D., Amphetamine-Resin Complex for Prolonged Appetite Suppression, *Annals of Internal Medicine*, June, 1956.

DIAGNOSIS AND TREATMENT OF EOSINOPHILIC GRANULOMA OF SKULL

Robert S. Knighton, M.D.
and
J. DeWitt Fox, M.D., Detroit

• *The diagnosis of eosinophilic granuloma of bone was made in five cases here reported; in each there was a circumscribed area of swelling or tenderness on a cranial bone, a characteristic circumscribed lytic lesion in the roentgenograms, and confirmation by microscopic examination of tissue obtained at operation. Headache attributable to extension of the tumor along meningeal blood vessels was severe in one case and present in two others; the intracranial pressure was normal and the neurological findings were negative in all cases. Surgical removal and subsequent irradiation to a total of 600 to 2,000 r in air was followed by healing and complete relief of symptoms. Eosinophilic granuloma should be considered as a diagnostic possibility whenever a patient presents a localized tenderness of the scalp or a lytic lesion of the skull.*

Eosinophilic granuloma of bone should be considered in the differential diagnosis of lytic lesions of the skull. First described as a clinical entity in 1940 by Otani and Ehrlich [1] and independently by Lichtenstein and Jaffe,[2] eosinophilic granuloma of bone has been the subject of increasing interest and controversy. Various authors feel that these solitary destructive lesions of the table of the skull are local evidence of a more generalized disease process. In 1942, Green and Farber [3] studied 10 cases and concluded that lipid histiocytosis of cholesterol type (Hand-Schüller-Christian disease), Letterer-Siwe's disease, and eosinophilic granuloma of bone were clinical expressions of the same basic disorder. Later, in 1944, Jaffe and Lichtenstein [4] advanced a similar thought but differed on etiology. In 1953, Lichtenstein [5] lumped these all under the single entity histiocytosis X. However, Otani and Ehrlich [1] felt that eosinophilic granuloma of bone, especially of the skull, should be classified separately from lipid histiocytosis of cholesterol type and Letterer-Siwe's disease, which carry a more serious prognosis and are of a more generalized nature. Eosinophilic granuloma of bone is primarily a disease of the reticuloendothelial system. At present, it is thought by some observers [6] to be infectious in nature, although no specific organism has been isolated.

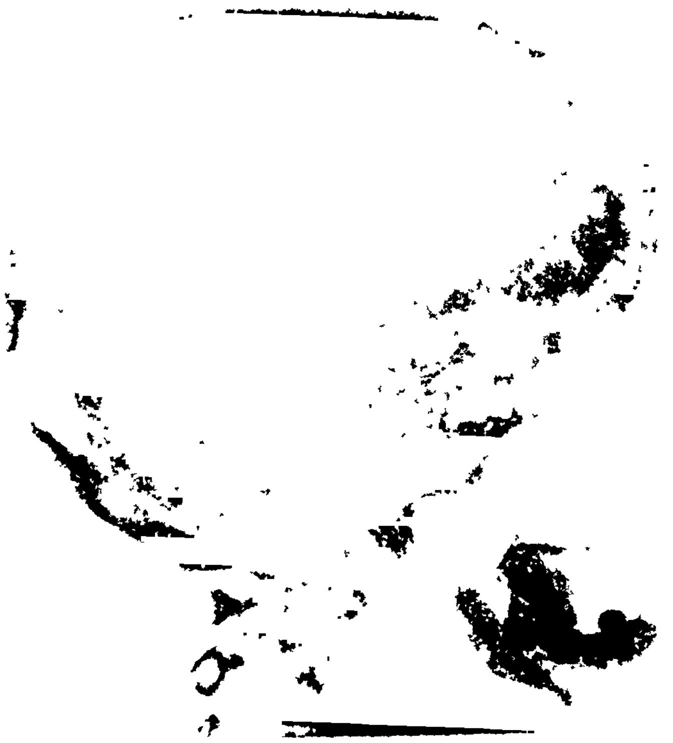

Fig. 1 (case 1).—Roentgenogram showing lytic lesion lying directly over branch of middle meningeal artery, which explains the symptoms of headache in this case.

Even as the controversy has arisen regarding the nature of this disease, so also have opinions differed on its treatment. Shuster and Flynn [6] favor surgical excision of the skull lesions, since drainage can be established if necessary. Gross and Savitsky [7] advise surgical excision in place of needle biopsy, since it provides a specimen for microscopic study and obviates roentgen therapy. Swain and Williams [8] describe perhaps the largest single skull lesion on record, which ended fatally but responded somewhat to surgery and roentgen therapy for a time. McCreary [9] records skin and bone involvement in a 2-year-old patient, with successful treatment with curettage of the bone and irradiation of the skin lesion. Curtis and Cawley [10] report multiple bone and skin lesions diagnosed by biopsy and clearing after irradiation. McCullough [11] claims good response to irradiation therapy of a skull lesion. He feels that this response supports the benign nature of this disease.

In the cases reported here, we wish to present the results achieved by combined surgical biopsy and roentgen therapy. The advantage of this plan of treatment is that it provides an adequate specimen for accurate microscopic diagnosis with the minimum of bone removal from the cranium. The roentgen therapy is followed by rather prompt regeneration of bone at the lesion site. The smaller the surgical lesion, the more rapidly this healing will occur. Since all of these cases consisted of solitary skull lesions that cleared remarkably after roentgen therapy, we, too, consider eosinophilic granuloma lesions of this character to be benign. However, we recognize that multiple lesions do occur. In these cases, the treatment is the same—surgical biopsy followed by irradiation. Sieracki [12] is also inclined to consider eosinophilic granuloma localized to bone as benign. It represents the successful confinement of the etiological agent.

From the Department of Neurological Surgery, Henry Ford Hospital.

Diagnosis

The history of onset of eosinophilic granuloma of bone is usually insidious. The patient may notice a tender spot on the scalp. His attention may be directed to it by a recent trauma to the skull, which may prompt a routine skull film. This may immediately disclose the lytic lesion. Clinically, however, the area may be swollen, with localized tenderness. On the other hand, the swelling may be painless. At times, the lesion may appear so rapidly and break through the outer table of the skull so quickly as to simulate a primary malignant tumor such as a sarcoma. The solitary lesion of the skull is the most common manifestation of the localized type of eosinophilic granuloma of bone. When multiple foci are present, other bones are involved in the following order of frequency: ribs, skull, femur, vertebrae, pelvis, mandible, and humerus.

The disease is most common in children and adolescents but has been reported in infants, young adults, and even middle-aged patients. Headache is sometimes a prominent symptom. This is especially true if blood vessels of the scalp or the dura mater are involved. In one of our patients (case 1) headache was severe due to invasion of the temporal bone, dura mater, and a branch of the middle meningeal artery. When a biopsy specimen of this lesion was examined, it was found to surround the artery and to be invading the dura mater. After its removal, together with a small segment of the dural branch of the artery, the headache disappeared. Blood-vessel involvement appears to be one cause of headache or localized tenderness of the scalp in these patients.

Neurological examination in our patients was negative. In none of these did the solitary, localized lesion produce any signs of increased intracranial pressure. Roentgenograms of the skull show a sharply circumscribed bone defect with geographical outline. The margins are well defined without surrounding sclerosis. Both tables are usually equally involved. Positive diagnosis must be withheld, however, until the surgical biopsy specimen has been examined microscopically. Microscopic examination reveals a loose stroma of reticular tissue with bone spicules and numerous eosinophils, leukocytes, and small lymphocytes with occasional multinucleated giant cells. No malignant change is seen. The following five case reports are illustrative of the therapy with combined biopsy and irradiation.

Report of Cases

Case 1.—The patient was a 38-year-old woman with a three-month history of left temporal headache, not throbbing in character, relieved by acetysalicylic acid (aspirin). There was no definite hemicrania or familial history of migraine. Neurological examination was essentially negative except for the finding of a small localized prominence over the left temporal region measuring about 1.5 cm. in diameter. There was no evidence of inflammatory change in the temporal artery on the affected side or the opposite side. Laboratory studies of the blood, urine, and serum were normal. Roentgenograms of the skull showed a lytic lesion over the left temporal bone about the size of a dime (fig 1). Chest films were normal. On Jan. 6, 1956, a biopsy specimen was taken from the left temporal bone lesion. This revealed eosinophilic granuloma that infiltrated the underlying dura mater and involved a branch of the middle meningeal artery. This area was clipped and the overlying granuloma removed and the bone curetted. Microscopic examination revealed eosinophilic granuloma that had involved the adventitial layer of the middle meningeal artery (fig. 2). There was also infiltration of the tumor into the area of the temporalis muscle. There were many large mononuclear cells and eosinophils in the adventitial areas of the small arteries. Sections of the tissue proper revealed many eosinophils, large mononuclear cells, and giant cells that appeared to be multinucleated. The patient received roentgen therapy immediately and was given 200 kv. of irradiation weekly to a total of 600 r in air. Her headache was completely relieved after the biopsy and clipping of the middle meningeal artery branch. There was gradual regeneration of bone after roentgen therapy. The patient has been seen in our outpatient department and had not had any recurrence after six months.

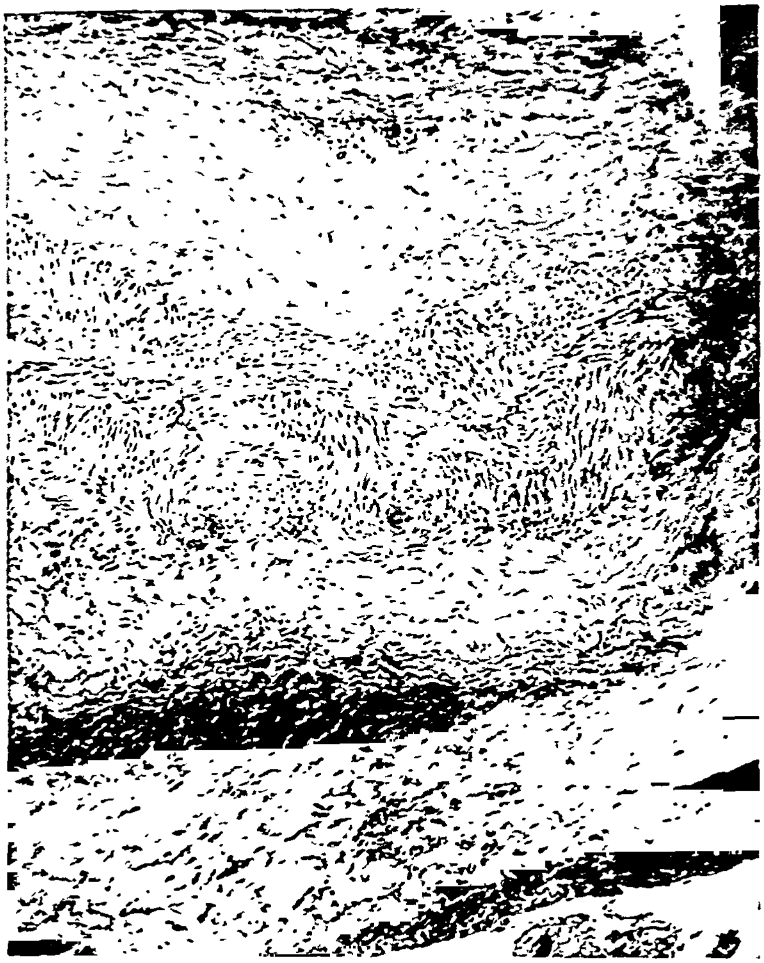

Fig. 2 (case 1).—Photomicrograph showing branch of middle meningeal artery. The eosinophilic granuloma surrounds the vessel but does not appear to invade the vessel wall (x 90).

Case 2.—The patient was a 6-year-old boy, first seen on Jan. 20, 1952, because of a swelling of the left eye of four months' duration. He had no visual disturbance and no pain. Neurological examination revealed an apparently normal 6-year-old boy, with no visual-field, funduscopic, or neurological abnormalities. Laboratory studies of the peripheral blood, urine, serum, and bone marrow were normal. Roentgenograms of the skull revealed an oval 1.5 by 1 cm. zone of destruction in the upper outer corner of the left superior orbital ridge. Chest films were normal. On Feb. 6, 1952, biopsy of the skull lesion revealed eosinophilic granuloma. A large amount of soft grayish tissue and periosteum was found. This was curetted for diagnosis. Microscopic examination showed the tissue to contain a conglomerate mixture of fibroblasts, epithelial cells, multinucleated giant cells, a few foamy histocytes, and a large number of eosinophils. The eosinophils were most prominent in the periphery of the lesion. The patient was given roentgen therapy of 100 r for six doses—a total of 600 r in air. After this there was a regression of the lesion and a gradual healing of the bone. Progress roentgenograms of the skull were essentially normal on Aug. 9, 1952, six months after treatment, and no recurrence was noted after four years of follow-up.

CASE 3.—The patient was a 32-year-old right-handed man who gave a history of headache for three months after he received a bump on the head while at work. There was no loss of consciousness, no bleeding, and no swelling, but the area struck, in the left parietal bone, continued to give pain. There was an associated frontal headache, dull and throbbing in character. Neurological examination was essentially negative except for slight tenderness over the left parietal area of the skull. Laboratory studies of the blood, urine, and serum were normal. A lumbar puncture was normal, with opening pressure 150 mm. H_2O. The cerebrospinal fluid was clear and colorless. The spinal fluid level of protein was 36 mg. and of sugar 72 mg. per 100 cc. The results of the Wassermann test were negative. An electroencephalogram and chest films were normal. Roentgenograms of the skull showed a 2-cm. rounded defect in the left temporoparietal area (fig. 3A.) On March 21, 1953, a surgical biopsy of the skull lesion was performed. This revealed eosinophilic granuloma. Microscopic examination showed a striking number of eosinophils intermixed with leukocytes and macrophages, scattered through a loose stroma of reticulated background (fig. 4 and 5). Bone spicules were present and showed marked scalloping, probably an index of the increased osteoclastic activity with very prominent cement lines seen in other bone spicules. No malignant change was noted. The patient was given roentgen therapy consisting of 100 r for nine doses and 200 r as a final dose, with a total of 1,000 r in air. Repeat roentgenograms of the skull taken July 11, 1953, showed evidence of healing in the left parietal bone (fig. 3B). Subsequent films, taken July 26, 1955, more than two years later, showed no evidence of the skull lesion and no recurrence elsewhere.

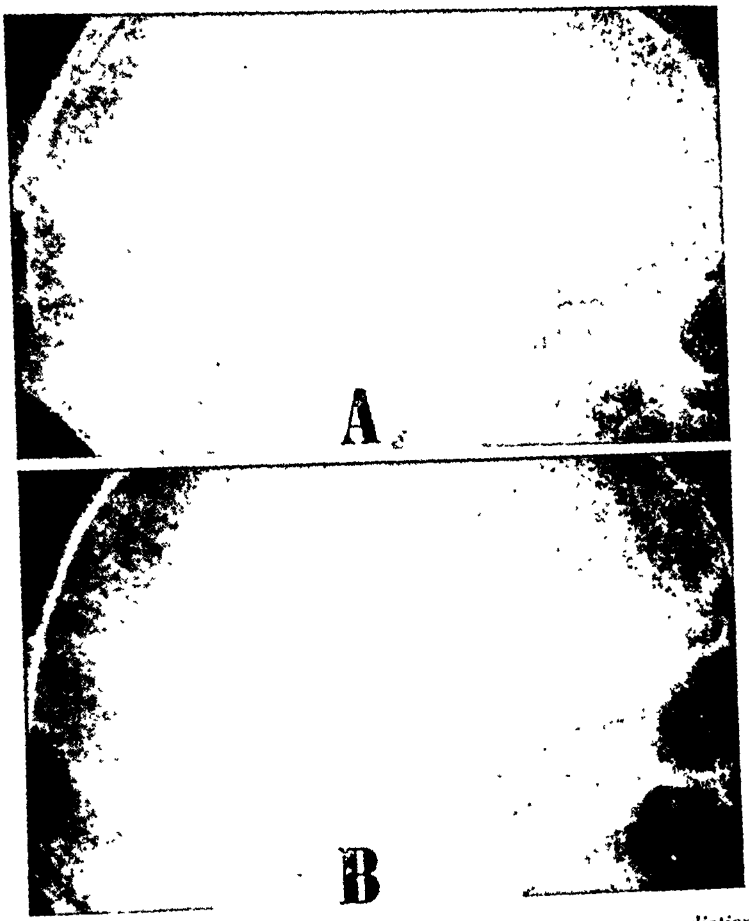

Fig. 3 (case 3).—*A*, roentgenogram of skull before biopsy or radiation therapy. *B*, roentgenogram of skull taken after radiation therapy with 1,000 r in air. Note complete healing of lesion in left parietal area. Film was en two years after therapy and shows no signs of recurrence.

CASE 4.—The patient was a 14-year-old right-handed boy who was in a fight on April 10, 1955. He suffered a blow to the left side of the head and was quite dizzy afterward. After this, he noticed a tender area in the left parietal region of his skull. Physical and neurological examination was negative. Laboratory studies of his blood, urine, serum, and blood chemistry were normal. A roentgenogram of the skull showed a radiolucent area in the left parietal region 2.5 cm. in diameter (fig. 6*A*). A chest film was normal. On May 18, 1955, biopsy and curettage of the lesion were performed. At operation the frozen section and imprint smear revealed eosinophilic granuloma, later confirmed on section. The lesion, measuring 2.5 cm. in diameter, was curetted up to the bony edge. Microscopic examination showed sections consisting of eosinophilic granuloma of the skull. These are composed of masses of cells set in a somewhat fibrous stroma. There were numerous eosinophils and a large number of nuclear cells. Occasional multinucleated giant cells were encountered. The remaining cellular structures were small lymphocytes, occurring in fairly large clumps. After biopsy and confirmation of the diagnosis by pathological section, the patient was given a series of two courses of radiation therapy, each consisting of 200 r at 10 different sittings. A total of 1,000 r in air was given over the left parietal area, and another course of 1,000 r in air was given in 200-r doses over the occipital area to a small second lesion. The patient has been free of any symptoms since irradiation, with no further head or skull pain. He has regrowth of bone in the former skull defect, as shown on the latest roentgenograms of the skull, taken one year later (fig. 6*B*). At follow-up, one year after treatment, no recurrence was noted.

CASE 5.—The patient was a 32-year-old right-handed female with a history of right supraorbital headache of one month's duration. She had occasional dizziness and a tender area over the right temporal area of the skull. Neurological examination was essentially negative except for the 2.5-cm. tender swelling in the right temporal area. Laboratory studies of the peripheral blood, urine, and serum were normal. Roentgenograms of the skull showed an irregular 1 by 1 cm. radiolucent area in the right frontal bone. A chest film was normal. On Oct. 23, 1954, a surgical biopsy was made of the skull lesion. A vascular and reddish purple lesion was curetted from the bone. The tumor extended through the inner and outer tables of the skull, but the dura mater was not involved. Microscopic examination revealed eosinophilic granuloma. The tumor was composed of eosinophils, with occasional neutrophils and plasma cells in a

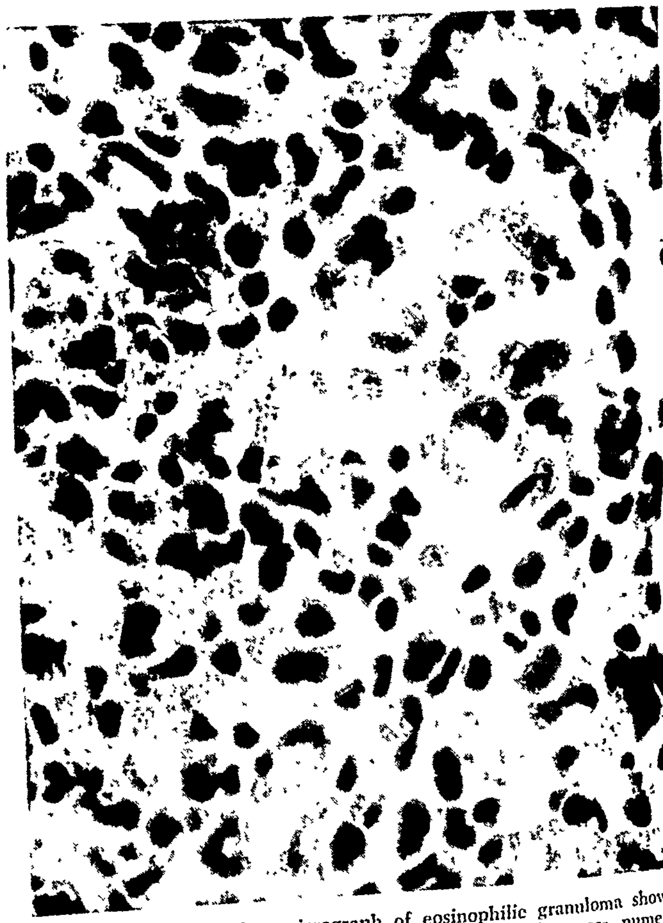

Fig. 4 (case 3).—Photomicrograph of eosinophilic granuloma showing loosely textured connective tissue stroma in which there are numerous eosinophils, giant cells, and histiocytes (x 710).

loose reticular stroma. The patient was given a total of 800 r in air. Her headaches and pain in the temporal region completely subsided, and she had no evidence of recurrence after 18 months. Repeat roentgenograms of the skull on July 26, 1955, showed no evidence of the previous lesion in the right frontal bone.

Comment

The diagnosis of eosinophilic granuloma of the skull often rests with the family physician or specialist who first sees the patient and suspects a lytic lesion. In any case of persistent localized tenderness of the scalp or localized headache, roentgenograms of the skull should be taken. This will almost invariably localize the lytic lesion and determine its size. The final diagnosis, of course, is a microscopic one after biopsy. In view of the unknown etiology of this lesion, no ironclad formula for its handling can be laid down. However, because it behaves in a benign fashion, as compared with Letterer-Siwe's disease and lipid histiocytosis of cholesterol type, it is deemed safe to handle it as a benign lesion. The cases presented tend to support this view. They were treated by surgical biopsy and irradiation, with immediate regression of the skull lesions. In the follow-up period, ranging from one to four years, no recurrence has been noted. However, should recurrence occur in later study, more radical therapy might be necessary. Until such time, it seems best to treat these lesions as outlined, i. e., by surgical biopsy and irradiation.

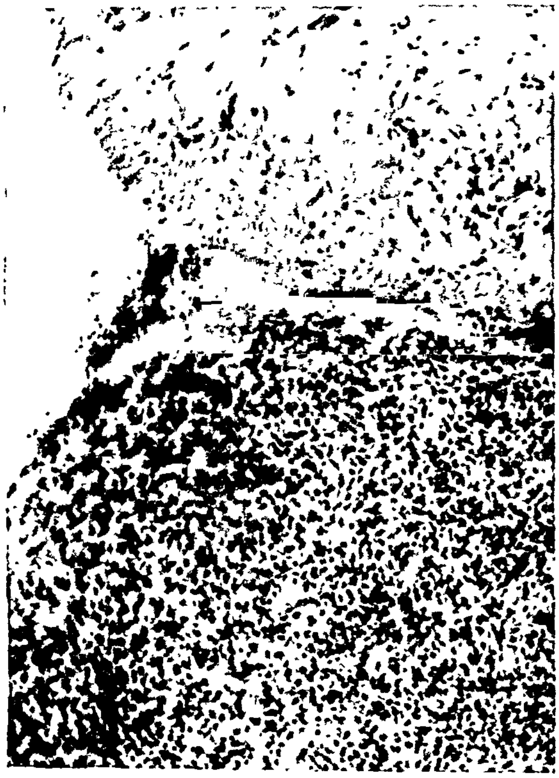

Fig. 5 (case 3).—Photomicrograph of eosinophilic granuloma showing junction of fibrous tissue and tumor (× 150).

Summary

Since 1952, we have seen five cases of eosinophilic granuloma of the skull. It is important to consider the possibility that this disease exists when there is any localized tenderness of the scalp or any lytic lesion of the skull. Since eosinophilic granuloma of the skull is frequently solitary and benign and carries a good prognosis, accurate diagnosis should be made by surgical biopsy, with removal of a specimen large enough for microscopic examination. The treatment is uniformly successful with roentgen therapy. Usually, a course of six exposures of 200 r in air is sufficient. The patient's scalp pain is relieved immediately after biopsy and irradiation. The regrowth of the bone of the cranium is usually demonstrated roentgenographically within six months.

2799 W. Grand Blvd. (2) (Dr. Fox).

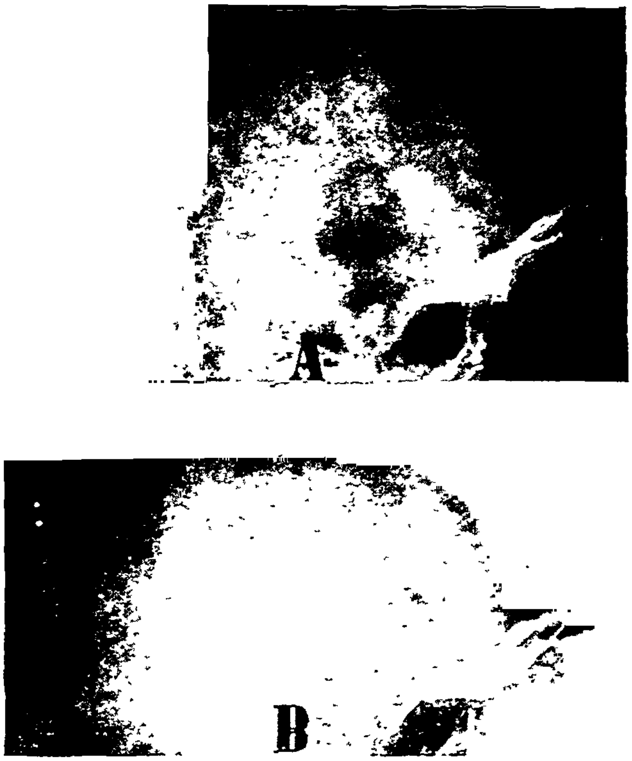

Fig. 6 (case 4).—*A*, roentgenogram of skull taken before therapy showing large lytic lesion in left temporoparietal area measuring 2.5 cm. in diameter. *B*, roentgenogram of skull taken one year after surgical biopsy and irradiation therapy with 1,000 r in air to lesion and a second course of 1,000 r in air to the occipital area for second lesion. Note almost complete healing of the lytic lesion and no evidence of recurrence.

Dr. Joseph E. Sieracki of the Department of Pathology, Henry Ford Hospital, procured and described the microscopic sections.

ried out on 13 healthy household associates of the 7 patients. Specimens were also collected from three nonhospitalized patients in the community.

Throat and rectal swabs were placed in tubes containing 2 ml. of tissue culture nutrient medium. Specimens were frozen either immediately at -20 C or after 24 hours' storage in a refrigerator. Stool specimens were prepared as 10 to 20% suspensions in tissue culture medium. The turbid stool suspensions and the throat and rectal swab eluates were clarified by centrifugation. Spinal fluids were used without treatment. For virus isolation, a 0.2-ml. aliquot from each specimen was inoculated into trypsin-dispersed monkey kidney monolayer tissue cultures (Melnick[1b]) in 16-by-125-mm. test tubes. The cells were propagated in a growth medium consisting of 97.5% Hanks' balanced salt solution, 0.5% lactalbumin hydrolysate, and 2% calf serum, with 200 units of penicillin and 200 mcg. of streptomycin added per milliliter. At the time of inoculation, the growth medium was replaced with 0.9 ml. of maintenance medium consisting of Earle's saline solution, lactalbumin hydrolysate, and calf serum. Specimens were inoculated into each of three tissue cultures and the tubes incubated at 36 C.

* + = positive; — = negative; N.D. = not done.

Microscopic observations for the appearance of viral cytopathogenic effect were made daily or every other day. Careful examination was made for evidence of cellular damage due to toxicity of the specimens. This was usually manifest within 24 hours. Stool inoculums were generally slightly toxic, while throat and rectal swabs were essentially nontoxic. Spinal fluids were also nontoxic and in fact appeared to have some nutritional value for the monkey kidney cells. Throat swabs and spinal fluids were considered negative at the end of a seven-to-nine-day incubation period unless there were changes in the kidney cells suggestive of viral effect, in which case the fluids were harvested and passaged a second time in tissue culture. Stool specimens or rectal swabs were considered negative only after two passages had been completed.

Identification of Agents Isolated.—The results of the virus isolation studies are tabulated in table 2. A total of 14 cytopathogenic agents were isolated. Virus was recovered from the stools of all seven hospitalized patients and from the throat swabs of four. No cytopathogenic agents were isolated from their spinal fluids. Two agents were recovered from stools of healthy household associates, while their other specimens were negative. One stool agent was recovered from a nonhospitalized patient. All 14 agents were examined in a tissue-culture neutralization test against prototypic poliomyelitis monkey antiserums. None of the 14 agents was neutralized by a mixture of the three types of poliomyelitis antiserums. It was therefore concluded that these agents were not poliovirus or a mixture of polioviruses.

Four stool agents (no. 11, 14, 18, and 28), from patients representing the four families studied, were examined in a virus neutralization test with Coxsackie prototypic antiserums of those types presently known to be cytopathogenic in tissue culture (types A9 and B1-5). None of these agents was neutralized by the above serums. In addition, the above four agents were inoculated into infant mice less than 24 hours old via the intraperitoneal route. There was no evidence of illness in the inoculated mice. In three instances, a second blind passage was made in infant mice with mouse brain-muscle suspensions; there was no apparent infection. Inoculation of the first-passage brain-muscle suspensions into tissue culture failed to demonstrate the presence of live virus and indicated a failure of the virus to survive through one passage in infant mice.

Since the Holland agents were not identifiable as poliomyelitis or Coxsackie viruses, according to both serologic and animal inoculation studies, they were designated at this point as orphan viruses. The following serologic studies were undertaken to elucidate the antigenic relationships of the 14 agents among themselves and to known ECHO virus types. Two of the fecal agents (no. 14 and 18) were selected for the preparation of specific antiserums. Rabbits were given 1 ml. of undiluted virus intravenously followed by five weekly doses of 1 ml. intramuscularly. Seven to 10 days after the last dose, the rabbits were exsanguinated by cardiac puncture. The antiserums thus prepared were capable of neutralizing 100 TCD_{50} of homologous virus in titers of 64 to 512. (All neutralization titers are expressed as reciprocals of the 50% serum dilution end-points.) All of the 14 orphan viruses were readily neutralized by either of the two Holland prototypic rabbit antiserums. It was thus apparent that the 14 orphan agents isolated in the Holland study were of the same serologic type.

In addition, the two Holland orphan strains were examined serologically with rabbit antiserums prepared against four other orphan viruses isolated from patients residing in other communities in western

New York who had had aseptic meningitis in 1955. Table 3 summarizes the results. It was found that the Holland agents were serologically related to two of the other four agents, one from Buffalo (no. 25) and the other from Springville, N. Y. (no. 8). The remaining two orphans from Batavia (no. 801) and Buffalo (no. 32) were found to be serologically alike but unrelated to the Holland group. For simplification, the Holland agents and serologically related orphan viruses were designated tentatively as Buffalo orphan prototype-1 (BOP-1), and the second serotype, representing the two orphan agents from patients no. 801 and 32, was designated as BOP-2.

§ + = positive, − = negative.

To determine relationship to presently known ECHO virus types, the 13 ECHO virus prototypes were examined in a virus neutralization test against BOP-1 and BOP-2 rabbit antiserums, with 100 TCD_{50} of each virus employed. ECHO virus type 6 was specifically neutralized by BOP-1 antiserum but not by BOP-2 antiserum. It was concluded that the 14 orphan viruses isolated from Holland patients with aseptic meningitis and their healthy family contacts, as well as two other orphan agents isolated from patients with aseptic meningitis, were serologically identical with the ECHO type 6 prototype. As has been noted in table 2, no viral agents were recovered from cerebrospinal fluid specimens from the seven Holland patients. However, during the investigation of the concurrent generalized outbreak of seasonal aseptic meningitis in western New York (July through September, 1955), a total of 10 orphan agents were recovered from cerebrospinal fluid specimens from hospitalized patients. Seven of these 10 agents have been found to be serologically identical with ECHO type 6.

Antibody Response in Patients

Poliovirus Antibody Studies.—The serums obtained during the acute and convalescent stages of the disease from the seven patients from Holland were studied for their circulating antibody to poliomyelitis. The antibody determinations were made by means of a metabolic inhibition test, with fourfold dilutions of serum used. During the course of illness, there was no demonstrable rise in poliovirus neutralizing antibody detected in any patient. It was concluded from the virus-isolation and serologic evidence that infection with any one type of poliovirus had not occurred during the period of illness.

ECHO Virus Type 6 Antibody Studies.—Antibody studies on the Holland patients' serums were carried out in a tissue-culture virus-neutralization test with ECHO virus type 6. Twofold dilutions of serum were tested against 100 TCD_{50} of ECHO virus type 6. Four tissue-culture tubes were employed per serum dilution. The 50% serum dilution end-point (Reed and Muench) was determined, based on readings made 48 hours after all virus control tubes showed definitive cytopathogenic effect. Table 4 summarizes the results obtained. The patients demonstrated rises in circulating antibody to ECHO type 6 virus in a characteristic manner. During the first three days of illness there was little or no demonstrable antibody. Between 5 and 12 days, circulating antibody to the virus appeared, although in modest titer. Seven months after infection, neutralizing antibody was still present. In view of the low order of neutralizing-antibody response, it was considered of interest to do determinations of the antibody content of human gamma globulin to ECHO virus type 6. Human gamma globulin was therefore employed in a neutralization test with one of the Holland agents (no. 14) and also with the prototype ECHO virus type 6. The antibody titers were 32 against each of the viruses. This titer is significant, although of low order.

Comment

Etiological relationship between a common endemic agent and a common clinical syndrome occurring simultaneously in a community is difficult to establish. Proof of such relationship must at the present time depend upon the demonstration of (*a*) association of the agent with clinical cases, (*b*) recovery of the agent from a parenteral site of disease (e. g., cerebrospinal fluid), (*c*) specific neutralizing antibody response during the course of illness, and (*d*) corollary epidemiological evidence within a localized outbreak.

Table 4.—*Neutralizing Antibody Titer Versus ECHO Virus Type 6 in Seven Patients with Aseptic Meningitis in Holland, N. Y.*

Patient No.	Day of Disease: 1	2	3	4	5	6	7	8	9	10	11	12	7-Mo Follow-Up

15			<2									9	4
16	<2									27			5
17	<2	<2								14			10
18			<2					27					27
23		<2					32						55

The need for careful evaluation of the role of the orphan viruses in disease is emphasized by the fact that orphan viruses have already been demonstrated to be worldwide in distribution and highly prevalent during the summer months. They have been isolated from fecal material from many areas in the United States[5] and also in Egypt,[1a] the Philippine Islands,[3] Canada,[6] and Sweden.[1b] Two recent surveys have shown that orphan viruses may be common enteric inhabitants. In one survey undertaken by Ramos-Alvarez and Sabin, of 1,566 healthy children in Ohio in the summer of 1953, 25 orphan viruses were recovered from the stools, or an over-all rate of 1.6%.[4a] In the group with the highest recovery rate, namely, children under 10 years of age who came to clinics from families with low income, the recovery rate was approximately 6%. These isolations fell into at least three serotypes. In a three-year survey of a healthy population of children in West Virginia, orphan viruses were recovered by Honig, Melnick, and coworkers in 33 instances from 1,558 stool specimens, a rate of 2.1%.[4b] The highest recovery rate, 11.2%, was from a low socioeconomic area in the four-month period from July through October.

The present demonstration of 7 ECHO 6 viruses among 10 orphan agents recovered from the spinal fluids of patients with aseptic meningitis in western New York is indicative of the invasive properties of this virus. Duncan, Rhodes, and others[6b] recovered two orphan agents, type unidentified, from the spinal fluids of patients with aseptic meningitis. Steigman, Kokko, and Silverberg isolated an orphan agent from the spinal cord of a child with a fatal infection that clinically and pathologically resembled bulbo-spinal poliomyelitis.[7] This agent has recently been identified serologically as ECHO virus type 2.[8] Further attempts to isolate and identify ECHO virus from spinal fluid and nervous tissue will be helpful in establishing the full range of the clinical central nervous system syndromes produced by ECHO viruses.

The Holland patients' neuralizing antibody response, although of a modest order, is in keeping with the low level of antibody for ECHO 6 found in pooled human gamma globulin. This may suggest that under natural conditions of infection the ECHO 6 virus is a poor antigen. However, the absolute level, dependent as it is upon the technique of mensuration, may simply reflect an artefact of the methods employed. With use of an analogous technique, neutralizing antibody titers against poliovirus are approximately tenfold to fiftyfold higher. If one assumes that the pooled gamma globulin represents an approximate twentyfold concentration of antibody, one can presume that the rather low titer of 32 suggests either a small number of adults with sustained high titers of antibody in the population or perhaps a larger number of adults with a barely detectable neutralizing titer. The serologic experience of the population is under study. Utilization of a rise in neutralizing antibody as a diagnostic tool appears to be feasible in this disease, since serum taken prior to the fifth day of disease will in general fail to show antibody and that taken after the fifth day will demonstrate a rise. This is in contrast to the serodiagnosis of poliomyelitis, where the neutralizing antibody has, in the majority of cases, attained maximal titer at the time of recognition of the disease and hospitalization.

The clinical course of illness of the Holland cases was typical of the syndrome known as aseptic meningitis. On admission, symptoms and signs of the patients could not be distinguished on clinical grounds from those of preparalytic poliomyelitis. In retrospect, several features distinguished the Holland cases of aseptic meningitis. First was the apparent high familial incidence of this illness as compared to that usually seen in poliomyelitis. As a corollary, the percentage of manifest versus inapparent disease appeared to be higher than in poliomyelitis. Second, it was noticeable that hot moist packs to the back (prone packs) were not required for more than two or three days, indicating the rapid subsidence of back and hamstring spasm. The significance of the mild muscle weakness and depressed deep tendon and superficial reflexes could not be properly assessed because of lack of controls.

There are already several indications that the association of ECHO virus type 6 with a localized outbreak of cases of aseptic meningitis as occurred in Holland may not be an unusual or isolated occurrence. Studies of a large epidemic of aseptic meningitis in all of western New York in 1955 indicate that such an association was widespread. Simultaneously, at the other end of the state, in Troy, an epidemic of presumably the same illness was studied by Dalldorf.[9] Many strains serologically identical with ECHO virus type 6 were isolated from patients' stools. An outbreak of nonparalytic poliomyelitis in Massachusetts during the summer of 1954 was recently described by Kibrick and others.[10] A high recovery rate of orphan viruses, largely ECHO virus type 6, was made from patients with this illness.

Summary

An outbreak of aseptic meningitis, involving 24 cases, including seven hospitalized children, occurred in Holland, N. Y., population 500, in July, 1955. The predominant clinical symptoms and signs included fever, frontal headache, signs of meningeal irritation, nausea and vomiting, generalized vague pains, minimal transitory muscle weakness, depression of superficial and deep tendon reflexes, and pharyngeal injection. All patients had a pleocytosis, predominantly lymphocytic. ECHO virus type 6 was isolated from 7 stools and 4 pharyngeal specimens of 7 hospitalized children, from 2 of 10 stools and none of 6 pharyngeal specimens of 13 healthy household associates, and from 1 of 3 stools of 3 nonhospitalized patients. All seven hospitalized patients developed a neutralizing antibody response to ECHO virus type 6 beginning on the fifth day of illness. The antibody was still present after seven months. Pooled human gamma globulin had a neutralizing antibody titer of 32 against this agent. In addition, 10 orphan agents were isolated from the spinal fluids of patients in other communities during the course of a subsequent generalized outbreak of seasonal aseptic meningitis in western New York. Seven of these agents were identified as ECHO virus type 6. The high virus recovery rate from stool and pharynx, the epidemiological data, the neutralizing antibody response during the course of illness, and the demonstration of virus

in the spinal fluid of patients are presented as evidence for establishing an etiological role for ECHO virus type 6 in seasonal aseptic meningitis.

Addendum

Since this paper was submitted for publication, Davis and Melnick[11] have reported 24 cases of aseptic meningitis associated with recovery of ECHO virus type 6.

This study was aided in part by contracts with the Communicable Disease Center, U. S. Public Health Service, Atlanta, Ga., and the Erie County (N. Y.) [illegible]

The [illegible] antiserum used in this study was supplied by [illegible] University of Kansas, Kansas City. The Coxsackie prototypic antiserum was supplied by Dr. Gilbert Dalldorf and Miss Grace Sickles, New York State Department of Health, Albany. The 13 ECHO virus prototypes were supplied by the Committee on ECHO Viruses. The human gamma globulin a 16.5% concentration without preservative, was supplied as C-262 by Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y.

Drs. Clinton Strong, Holland, N. Y., and A. Wilmot Jacobsen, Buffalo, made available clinical data on their patients for this study.

METHYLPHENIDATE (RITALIN) HYDROCHLORIDE PARENTERAL SOLUTION

PRELIMINARY REPORT

John T. Ferguson, M.D., Frank V. Z. Linn, M.D., John A. Sheets Jr., M.D.
and
Mervyn M. Nickels, M.D., Traverse City, Mich.

• *Methylphenidate hydrochloride was administered in 10-mg. doses by intravenous injection to 164 hospitalized mental patients who manifested sleepiness and other symptoms of overdosage with tranquilizing drugs. The conditions of only 4 of the 164 were refractory to the analeptic effects of the methyphenidate; the other 160 all responded to one, two, or at most three injections by increase in alertness and decrease in side-reactions. Safe and effective dosages were thus determined, and in addition it was found that the improved condition of 151 of the 160 patients could be maintained by giving the methylphenidate solution thrice daily by mouth. A group of 11 chronic, regressed, underactive patients were then treated with intravenous injections of the drug. Three injections of 10 mg. sufficed in every case to cause marked clinical improvement, with increased activity, sudden awareness of surroundings, and other marked changes of behavior. These changes were obtained repeatedly, appeared promptly, were of limited duration, and were not seen after injections of a placebo. They are exemplified in the case histories of two patients who, after 21 and 17 years of extreme inactivity in the hospital, showed dramatic improvement in behavior.*

The psychoanaleptic activity, or stimulating activity on the central nervous system, of orally administered methylphenidate (Ritalin) hydrochloride is well documented clinically.[1] However, clinical information concerning this drug in a new form, methylphenidate (Ritalin) parenteral solution (1%), is needed. This report, although covering our observations made during approximately six months of intravenous administration of this solution to 164 hospitalized mental patients, has been prepared primarily as a preliminary report of findings observed when this solution was administered to 11 chronically regressed, negative, and underactive patients who had been hospitalized for an average of 16 years.

Effects of Drug

In our preliminary evaluation of methylphenidate parenteral solution, we first administered the drug intravenously to patients demonstrating sleepiness, lethargy, tremors, drooling, nasal congestion, conjunctivitis, and Parkinson-like gait produced by too much reserpine, promazine, or chlorpromazine hydrochloride. One hundred six of the 164 patients who received 10 mg. (1 cc.) of the solution intravenously demonstrated improvement of their mental alertness and a

---

From the Traverse City State Hospital.

decrease in their side-reactions within 5 to 90 minutes after the injection. Thirty-eight of the 164 responded only after a second intravenous injection of 10 mg. was administered, and 16 of the remaining 20 required 30 mg. intravenously before a clinical change was recorded. The remaining 4 of the 164 showed no change, even though their dosage was raised to 90 mg. intravenously.

After administering 10 to 30 mg. intravenously, as individually needed, three times daily for periods ranging from 24 to 72 hours (three to nine injections), we have been able to maintain the improved condition of 151 of the 160 patients with a comparable dose of methylphenidate given orally three times a day. During the period that the methylphenidate solution was administered intravenously, we recorded no gross change in blood pressure, pulse, or respiration for 160 of the 164 patients. Eight of the 164 became apprehensive and fearful after two to four injections, and 8 others became overactive. These symptoms were alleviated when the dosage was decreased. There was no evidence of serious changes of the skin or tissues at the site of injection, even when extravasation occurred on a few occasions; also there was no evidence of phlebitis. Thus it is indicated that this parenteral solution seems to be well tolerated locally as well as systemically.

From the 164 patients we had acquired a knowledge of indication for use of the drug as well as the proper dosage, safety, and activity of the drug. This prompted us to try a course of therapy with methylphenidate parenteral solution on a group of chronically regressed, underactive patients. Our basic requirements for the patients were simple: a long history of underactivity, no visible reaction when a towel or other object was tossed toward them, and a behavior pattern that indicated they needed help in executing routine daily tasks. Eleven such patients were chosen from another service. An initial intravenous injection of 10 mg. of methylphenidate parenteral solution produced no clinical change in the 11 patients. However, after the second 10-mg. injection and more noticeably after the third intravenous injection of 10 mg. was administered, there was marked clinical improvement in all 11 patients—within minutes. To illustrate the type of patient in this special study and to give examples of our method of administering the solution, two cases are presented.

Report of Cases

Case 1.—A 44-year-old male had been admitted to the Traverse City State Hospital in 1935. He never talked, even when prodded. During the 21 years of his hospitalization he spent practically every waking hour sitting in a chair in the same corner of the same ward without moving. He had to be started to meals, told to go, and helped at the toilet. He needed help in dressing and undressing. He made no visible reaction when a towel was repeatedly thrown to him. At 2:50 p.m. on Sept. 5, 1956, he was given 10 mg. of methylphenidate parenteral solution intravenously. He showed little response. At 2:53 p.m. of the same day he was given a second 10 mg. intravenously. At 2:56 p.m. he caught a baseball when it was thrown to him and soon was playing catch with the nurse. At 5 p.m. he got in line for supper, after going to the toilet without being told to do so. In this short time he demonstrated more voluntary movement and more mental alertness than had been seen during the total of his 21 years in the hospital. This new pattern lasted approximately five hours. On Sept. 9, 1956, the experiment was repeated, with the administration of a single 30-mg. intravenous injection. The response was even more dramatic. In less than five minutes the patient was not only playing catch but was able to examine the ward as if it were his first time to see parts of it, although he had been a patient there for 21 years.

Case 2.—A 41-year-old male had been admitted to the hospital in 1939. During the 17 years that he had been a patient he had never been known to move without help. If his arms or legs were placed in some unorthodox position, they would remain as placed for hours. He needed help and prodding for his every act. At 2:55 p.m. on Sept. 5, 1956, he was given 10 mg. of methylphenidate parenteral solution intravenously. At 2:58 p.m. he was given the second 10 mg. intravenously, and at 3 p.m. he was given another 10 mg. intravenously, thus making a total of 30 mg. At 3:05 p.m. he was playing catch with the nurse and the patient discussed above. His mental awakening lasted approximately four and one-half hours. On Sept. 9, 1956, the experiment was repeated, with the administration of a single intravenous injection of 30 mg. Within five minutes he was playing catch, although he seemed more interested in his hands—as if testing every possible movement.

Comment

On Sept. 12, 1956, the 11 chronically regressed, underactive patients of the special group who had been tested with methylphenidate parenteral solution were tested with placebo injectable solution. Four received as much as 100 mg. (10 cc.) intravenously, without any change from their old pattern. The day after the placebo had been given, the 11 patients were then given 20 to 30 mg. of methylphenidate parenteral solution intravenously. All responded to the drug as they had previously. During the experiments, blood pressure level and pulse and respiration rates were recorded. No changes of significance were recorded.

Therapy with methylphenidate parenteral solution was not continued in 4 of the 11 patients, in order that we may clinically evaluate the activity of other analeptics. This work is in a preliminary stage. However, at this time, none of the other drugs so far tested have produced the dramatic response seen with methylphenidate parenteral solution. Six of the seven patients in whom therapy with orally given methylphenidate has been continued have shown a slow, steady improvement, almost in proportion to the time and retraining they have been given. The improved condition of one patient is maintained only when he is given methylphenidate parenteral solution intravenously or intramuscularly.

Because of its safe, fast action in overcoming most of the so-called side-reactions of the tranquilizing drugs and because of the improvement we have witnessed in chronically underactive patients, the parenteral form of methylphenidate gives promise of opening new doors in our quest to eradicate mental illness. Further studies are recommended.

The methylphenidate hydrochloride used in this study was supplied as Ritalin parenteral solution (1%) by Ciba Pharmaceutical Products, Inc., Summit, N.J.

GENERALIZED CYTOMEGALIC INCLUSION DISEASE IN NEWBORN INFANTS

McLemore Birdsong, M.D., David E. Smith, M.D., Fred N. Mitchell, M.D.
and
J. Hicks Corey Jr., M.D., Charlottesville, Va.

• *Generalized cytomegalic inclusion disease is an intrauterine infection that, in its most serious form, causes symptoms at or soon after birth. The two infants here described had icterus, extensive petechial or ecchymotic hemorrhages, hepatomegaly, splenomegaly, and various laboratory findings indicating a severe blood dyscrasia. One infant died an hour after birth; the other at birth exhibited signs of hemolytic icterus and an anemia that progressed at first but was ultimately controlled. Numerous fresh urine specimens obtained from the second infant during the first two weeks yielded a sediment that, on fixing and staining, exhibited enlarged cells with typical cytoplasmic as well as intranuclear inclusions. The second infant is one of three now known to have survived this disease. The causative organism is a salivary gland virus that probably infects a large proportion of the population subclinically at an early age. The infant who survived was treated with vitamin K intramuscularly, benzathine penicillin G orally, prednisolone, and corticotropin.*

The purpose of this paper is to discuss the clinical picture, etiology, and pathology of cytomegalic inclusion disease as seen in infancy and to describe two cases. One case was diagnosed by the examination of urinary sediment and is the third reported case with recovery of the patient; the second case was diagnosed at autopsy and is typical of the usual past experience with this disease.

Report of Cases

Case 1.—A 2,280 gm. (5 lb.) female was born after eight months gestation terminated by a normal labor and an uncomplicated spontaneous delivery. Both parents were blood type O, Rh positive. At birth the infant was moribund and had severe jaundice, with ecchymoses noted over the back. The head and buttocks appeared abnormally small. A grade 1 precordial murmur was heard, and the cardiac rate was found to be variable. The respirations were irregular, numbering only one to two per minute. The liver was palpable at the iliac crest, and the spleen was similarly enlarged. Ecchymoses became progressively widespread, and the patient's condition deteriorated rapidly, with death occurring one hour after birth. A venipuncture was performed shortly after birth, and bleeding continued for several minutes after death.

The white blood cell count was 80,000 per cubic millimeter, corrected to 38,100; a differential count showed 4 band cells, 18 polymorphonuclear cells, and 78 lymphocytes. The hemoglobin level was 10 gm. per 100 cc. There were 300 nucleated red blood cells per 100 white blood cells, there was marked anisocytosis of the red blood cells, and there were no demonstrable platelets. The infant's blood type was O, Rh positive. The direct Coombs' test was negative, and the Wassermann test was negative. Studies on the mother's blood failed to reveal any abnormal agglutinins. It was impossible to carry out other studies.

Postmortem Examination.—On gross examination the principal findings were slight icterus, widespread petechiae, and marked enlargement of the spleen and liver. Petechiae were present on all the body surfaces; in the mucosa of the esophagus, stomach, ileum, colon, and urinary bladder; in the pleura; and in the kidneys. The heart was normal. The lungs were airless, moist, and heavy. They contained hemorrhages that were particularly prominent in the interlobular septums. The abdomen contained a small amount of icteric fluid, and there was a generalized enlargement and reddish discoloration of the lymph nodes in the mesentery, mediastinum, and retroperitoneal regions. The liver was greatly enlarged to a weight of 156 gm. and extended 5 cm. below the costal margin, as did the spleen, which weighed 52 gm. The kidneys were slightly enlarged, and their cortical architecture was obscured by multiple dark hemorrhagic areas. In the cranial cavity there was a small amount of clotted blood of undetermined origin on top of the tentorium. The brain was of normal size and configuration and contained no lesions on sectioning.

Microscopically the principal lesions were the cells with inclusions and widespread extramedullary hematopoiesis, consisting principally of erythroblastic cells but including myeloblasts and usually accompanied by appreciable interstitial hemorrhage. The inclusions (fig. 1) were of typical type and occurred in greatly enlarged cells. The intranuclear inclusions were very large, ovoid, amphophilic, and rather homogeneous. They were surrounded by halos devoid of chromatin, and the chromatin was condensed upon the distended nuclear membrane. Examples of the irregular basophilic cytoplasmic inclusions were much less numerous than those of the intranuclear inclusions. These inclusions were present in the ducts of the parotid gland; large cells that lay loose in the alveoli of the lungs; the ducts; and other epithelial cells in the portal spaces of the liver, the pancreas (where the islets of Langerhans were particularly involved), tubular epithelium in the kidney, and the pituitary, thymus, and thyroid. One example was found in an endothelial cell in a cervical node. In the brain, several inclusion-bearing cells were present in the neonatal glial mass beneath the ependyma of the lateral ventricles.

Extramedullary hematopoiesis accompanied by significant hemorrhage (fig. 2) was present in the kidneys, liver, and lungs. Hematopoietic tissue without hemorrhage was seen in the spleen, lymph nodes, and thymus and to a slight extent in the epicardium, adrenals, uterus, and pituitary. The liver showed considerable disarrangement in addition to the inclusion cells and the hematopoiesis and hemorrhage. The liver cell cords were poorly developed, and the portal spaces were enlarged and contained irregular and broken cholangioles and an infiltration by lymphocytes and leukocytes. The bone marrow was solidly cellular and contained an excessive proportion of erythroblastic cells but no other abnormalities.

Case 2.—A 2,580 gm. (5 lb. 11 oz.) male was admitted by birth to the newborn service of the University of Virginia Hospital on Oct. 28, 1955. The mother, blood type A, Rh positive, was a primigravida who had experienced an uncomplicated nine-month pregnancy. Labor was complicated by mild preeclampsia. Delivery was facilitated by the use of low forceps. The infant demonstrated the following positive physical findings: (1) a mild degree of icterus of the scleras, a generalized petechial and purpuric eruption, and scaling of the hands; (2) lethargy, although the Moro reflex was active and bilaterally equal; and (3) the spleen palpable 4.5 cm. below the left costal margin and the liver palpable 2 cm. below the right costal margin. On the second day of life a grade 1, high-pitched, systolic, nonradiating murmur was heard at the left sternal border in the fourth and fifth left intercostal spaces.

The initial laboratory studies demonstrated anemia, bilirubinemia, prolonged bleeding time, and poor clot retraction. The bone marrow showed no megakaryocytes, an increased number of nucleated red blood cells, and an over-all decrease in cellular-

ity. Subsequent blood studies showed progressive anemia, which eventually stabilized, reticulocytosis, and a marked depression of the thrombocytes. Results of other laboratory tests included the following data: Blood type O, Rh negative, Coombs' test negative; Kline test negative, blood cultures negative, and parental blood group incompatibilities absent. Maternal platelet count was 110,000 per cubic millimeter (direct), and studies for toxoplasmosis on the infant and mother were negative. Results of Van den Bergh's test were direct negative and indirect 6 mg. per 100 cc. on Oct. 28, 1955, the indirect being 0.2 mg. per 100 cc. on Nov. 28, 1955. Repeated white blood cell counts and smears were regarded as normal. A urine specimen on Nov. 1, 1955, contained 2 + albumin and 3 to 5 coarse granular casts but was otherwise normal. Stool examination, including trypsin activity, was normal. At birth the coagulation time was 3 minutes, 24 seconds; clot retraction time two hours; and the bleeding time 30 minutes. Thymol turbidity was 4.6 units, and the methylene blue dye test was negative. The platelet counts and serum protein analysis are given in the table. X-rays of the skull and long bones were normal, and funduscopic examination by an ophthalmologist failed to show any abnormalities. Beau's lines were noted on the 16th hospital day.

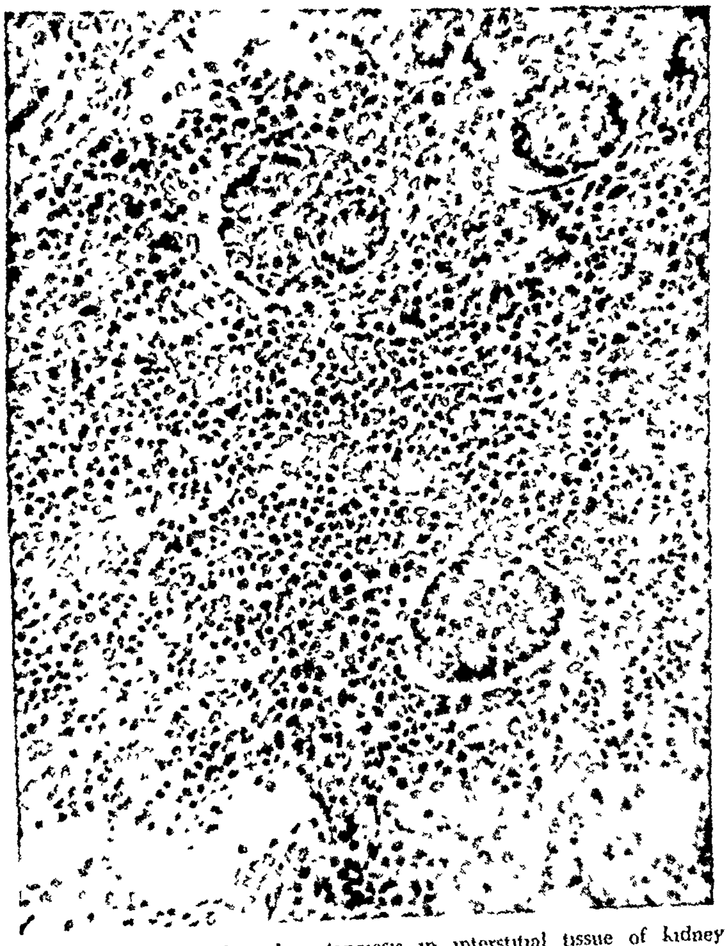

Fig. 2.—Extramedullary hematopoiesis in interstitial tissue of kidney (case 1). These foci were often accompanied by hemorrhage (× 240).

Upon admission to the nursery for newborn infants, the patient was given 5 mg. of vitamin K intramuscularly. Oral administration of benzathine penicillin G (Bicillin), 50,000 units, was begun twice daily. The infant was placed on therapy with prednisolone (Meticorten) given in divided doses of 30 mg. the first day, 20 mg. the second day, and 15 mg. daily thereafter for a period of two months, at which time the steroid therapy was discontinued while corticotropin was administered. During the first two weeks of the 26-day hospitalization, numerous fresh urine specimens were obtained. The sediment was fixed in formaldehyde, and the smears were stained with hematoxylin-eosin and Wright-Giemsa stains. Cells typical of cytomegalic inclusion disease were demonstrated on several occasions (fig. 3). During the three and one-half months of follow-up examinations, clinical progress was satisfactory, without evidence of jaundice and purpura, even though there was some persistence of anemia and diminished production of megakaryocytes on bone marrow examination.

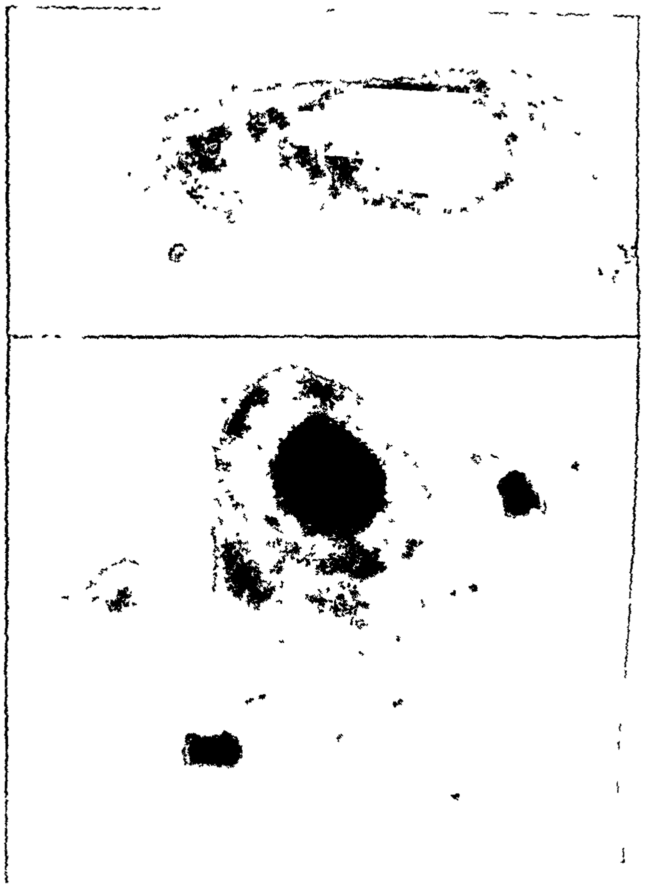

Fig. 3.—Two epithelial cells with intranuclear inclusions from urinary sediment (case 2). The cells were generally sufficiently disrupted that no clear examples of the cytoplasmic inclusions were found (× 1,300)

Comment

History, Etiology, and Clinical Findings.—The salivary gland viruses are the etiological agents of human cytomegalic inclusion disease and of related conditions in many species of animals. These viruses are ubiquitous infectious agents whose names are derived from the early recognition that their characteristic lesions occurred most frequently in salivary glands. The inclusions formed by the action of the viruses were first confused with protozoa, but in 1926 Cole and Kuttner [1] showed that typical lesions in guinea pigs were due to a transmissible and filterable agent. It was then discovered that there were a number of agents that produced the characteristic lesions in various animals but that each strain was species-specific. Except on inoculation into very young animals, the infections produced by these viruses are innocuous.

Knowledge of the human infection has rested on the analogy of the morphological changes in human tissues with those in animal tissues until recently, when Smith[2] successfully propagated the human virus in tissue cultures. Evidence of infection by this virus may be found in tissues under three principal circumstances: (1) incidentally in the salivary glands, (2) in various organs of children and adults who have been ill with other diseases, and (3) disseminated throughout many organs in the newborn infant.

The incidence of the typical inclusions within the salivary glands in routine autopsies of children has been reported as 10 to 32%.[3] This strongly suggests that this virus subclinically infects a large proportion of the population at a relatively young age. The disseminated occurrence of the inclusions in older children and adults has usually been observed in association with other severe diseases and is probably beyond the salivary gland. The generalized disease in the newborn infant appears to be a primary infection by the virus.

Platelet Counts and Serum Protein Analysis of Patient (Case 2) Who Recovered from Cytomegalic Inclusion Disease

	Platelet Count Cu. Mm.
10/28/55	300,000
10/29/55	4,000
11/ 1/55	20,000
11/ 3/55	12,000
11/10/55	16,200
11/14/55	12,700
11/28/55	26,000
12/15/55	68,000
1/ 6/56	79,000
2/ 9/56	114,000
3/ 2/56	63,000
3/ 6/56	58,000

Serum Protein Analysis 2/14/56	Values Found	Normal Values
Total Protein Gm./100 Ml.	6.67	7.35
Serum Protein Pattern (Paper Electrophoresis)		
Albumin, %	52.7	59.4
Alpha 1, %	6.3	6.0
Alpha 2, %	14.4	9.5
Beta, %	15.6	10.7
Gamma, %	11.0	14.4

Although no significant illness has ever been recognized in the mothers of these infants, it is very interesting that the mothers are often primigravida and from relatively isolated rural homes or communities. Such circumstances suggest that this condition results when the mother has an initial, subclinical infection with the virus coincidental with her pregnancy. As no cases have been reported of the occurrence of generalized infantile cytomegalic inclusion disease in more than one child of a given mother and since it appears that most adults have had the infection at some time in their lives, it appears that infection of the mother prior to her pregnancy presents no danger.

The generalized infantile disease may be due to either an intrauterine or a postnatal infection. In the case reported by Gallagher,[4] an infant developed a pulmonary infiltration that progressed to cyst formation in early infancy. On removal of the involved lobe of the lung when the child was 2 months old, typical inclusion bodies were discovered in the bronchial epithelium. This infant survived and apparently has had no recurrence of the disease. Several other cases, such as that of Bacala and Burke,[5] present histories of normal neonatal periods with the subsequent onset of illness during early infancy. Varied symptoms, including vomiting, diarrhea, failure to gain weight, chronic eczema, convulsions, and cyanosis, were described by these authors and they suggested that signs and symptoms might be expected to vary depending upon the organs and tissues most severely damaged by the virus. Cases of congenital brain damage, with calcification, similar to those caused by toxoplasmosis have also been described, and it is suspected that some of these infants may survive.[6]

In the most serious form of the disease, symptoms occur at or soon after birth. This severe generalized infantile disease, as illustrated by the two cases in this report, is apparently due to an intrauterine infection. The signs and symptoms are immediately apparent in the postnatal period, and evidence of the active disease has been seen in stillborn infants. As in hemolytic disease of fetus and newborn infant, the infants are born with some evidence of the disease and develop alarming symptoms in the first few days. The usual signs and symptoms are jaundice, hepatomegaly, splenomegaly, purpura, thrombocytopenia, and hemolytic anemia. Other less frequently described findings are intracranial calcifications, cerebral hemorrhage, convulsions, and cyanosis.[6] Late-occurring symptoms include vomiting, diarrhea, failure to gain weight, and chronic eczema.[5]

The differential diagnosis is that of jaundice, hemolytic anemia, and thrombocytopenia. Diseases that should be considered are hemolytic disease of fetus and newborn infant (Rh, ABO, and other blood incompatibilities), congenital syphilis, spherocytosis, nonspherocytic hemolytic anemia, congenital obstructions of the bile ducts, acute sepsis, toxoplasmosis, and galactosemia, as well as other less common considerations. Fetterman[7] was the first to show that the diagnosis can be made by careful examination of fresh urinary sediment. The finding of tubular epithelial cells with the characteristic inclusions in the sediment is diagnostic of cytomegalic inclusion disease. At the present time, this is the only way to make the diagnosis in the living patient, except by removal of tissue for histological study.

Treatment

At this writing little is known concerning the treatment of cytomegalic inclusion disease. Margileth,[8] in the medical management of the first surviving patient, used cortisone. In our surviving patient steroids were also used. The rationale for steroid therapy was based on recognition of the severe hemolytic features and the knowledge that in other hemolytic diseases cortisone has been helpful. The mechanism of the hemolytic process is not known exactly, but it seems reasonable to assume that, since cytomegalic inclusion disease is caused by a virus, abnormal antibodies might account for the finding of a hemolytic process in these cases. Cortisone has also been used successfully in the treatment of thrombocytopenia, which is a characteristic feature of this disease and which was extremely severe in our patient.

Exchange transfusion has been advocated but not yet reported in the treatment of cytomegalic inclusion disease. The hematological findings represent those of a hemolytic anemia secondary to the viral infection. It would seem that exchange transfusion would be useful in temporarily decreasing the circulating antibody, assuming that an abnormal antibody is present. This form of therapy should be given serious consideration in cases diagnosed in the future. Gamma globulin has been recommended in the treatment of this disease, but we can find no rationale for its use. Antibiotics may be used prophylactically, with no idea of affecting the course of the primary disease process.

Summary

Of two cases of generalized neonatal cytomegalic inclusion disease, in one, a nonfatal case, the diagnosis was made clinically and confirmed by demonstration of inclusions in cells in the urinary sediment; in the other, the clinical and pathological features were typical of most previously reported cases. This disease is an intrauterine virus infection and is characterized by icterus, hemolytic anemia, thrombocytopenia, and other manifestations. At present there appears to be a rationale and clinical evidence for the use of cortisone in treatment of recognized cases. Exchange transfusions might be useful, but specific therapeutic agents are not presently available.

Addendum

The patient in case 1 was seen on Sept. 14, 1956, at which time his physical examination was negative and his weight was 8,504.9 gm. (18 lb. 12 oz.). Both his physical and mental development appeared to be normal.

CLINICAL NOTES

FATAL AGRANULOCYTOSIS OCCURRING DURING PROMAZINE (SPARINE) THERAPY

Doris J. Woodward, M.D.
and
James D. Solomon, M.D., Ph.D., Washington, D. C.

Promazine (Sparine) is 10-(3-dimethylaminopropyl) phenothiazine hydrochloride, one of the newer ataraxic drugs recently introduced into clinical practice. It is chemically related to chlorpromazine, both compounds containing the phenothiazine nucleus. The structure of promazine is the structure of chlorpromazine minus the chlorine atom. Promazine has been used in the management of patients with acute mental disturbances[1] and at this stage is not recommended for patients with chronic conditions. Nevertheless, a clinical trial in such patients was planned. In March, 1956, it was decided to give a course of promazine therapy to 97 patients (50 female, 47 male), all with chronic conditions, who had been hospitalized for from 5 to 25 years. So far as is known, there has been no report in the literature of a case of agranulocytosis resulting from promazine therapy. In order to furnish the first known direct evidence of toxic effects of promazine on the bone marrow, we consider it of interest to report a case of fatal agranulocytosis occurring in a patient during administration of this drug.

Report of a Case

A 57-year-old female was admitted to the psychiatric service on Feb. 25, 1937, with a diagnosis of schizophrenic reaction, paranoid type. The onset of her mental illness was insidious and extended over a period of years. On admission, the physical examination showed nothing essentially abnormal. Psychiatric observation revealed no significant changes over the years. She was seclusive, irritable, hostile, and noisy and did not take part in ward activities. Her speech was rambling, incoherent, and at times difficult to understand because of a marked German accent. She had hallucinosis. The patient had not previously received any of the ataraxic drugs, and there was no history of any convulsive disorders. Blood studies prior to promazine therapy showed a white blood cell count of 8,200 per cubic millimeter, a hemoglobin level of 15.4 gm. per 100 cc., and a hematocrit value of 42%. The total serum bilirubin level was 0.32 mg. per 100 cc.,

---

From the Psychiatric and Medical Service, St. Elizabeths Hospital.

with direct 0.1 mg. and indirect 0.22 mg. Urinalysis (not a catheterized specimen) showed a specific gravity of 1.022 and was negative for acetone, albumin, and sugar, with an occasional white blood cell being seen on the microscopic examination. X-ray of the chest was negative.

Promazine therapy was started June 4, 1956. The initial dosage was 100 mg., 200 mg., and 400 mg. for the first, second, and third days respectively. After the third day, the dosage was increased by 100 mg. per day each week until a total daily dosage of 1 gm. was reached (July 16, 1956). All medicaments were given by mouth and in divided doses three times daily. On July 3, 1956, the three times daily dosage was changed to four times daily. Temperature, pulse and respiration rate, and blood pressure were taken daily during the first two weeks of therapy and showed no marked variation from normal. The patient's mental status showed little, if any, improvement at this period of treatment.

On July 6, the 31st day of promazine therapy, blood studies revealed a white blood cell count of 3,800 per cubic millimeter, with a differential count of 60% neutrophils and 40% lymphocytes. The hematocrit value was 38%. The patient's temperature was normal, and physical examination revealed no evidence of infection, sore throat, or ulceration of the mouth. No enlarged lymph nodes were palpable. The treatment with promazine was continued, with daily inspections and observations of the patient.

On July 20, the patient was noted to be unusually confused and unsteady on her feet and was reported to have fallen in the bathroom late in the afternoon. Her temperature was normal, and physical examination revealed no positive findings. On July 21, the 46th day of therapy, the patient had a petit mal seizure lasting two minutes. There was no injury. At this time there was a rectal temperature of 102.8 F (39.3 C). The patient was responsive and there were no positive physical findings. She was given 10 grains (0.6 gm.) of aspirin and fluids by mouth.

On July 22, the patient's temperature in the morning was up to 103 F (39.4 C). The only positive physical finding was fecal impaction. An enema was given. The fluid intake for the previous 24 hours had been 1,590 ml., and the output was 400 ml. Promazine was withdrawn. At this time, medical consultation was requested, and the patient was transferred to the medical and surgical branch in the afternoon. Physical examination at the medical and surgical branch revealed these positive findings: scleras, slightly icteric; lungs, dulness at left base with increased breath sounds and a few coarse rales; heart, pulmonic second sound greater than the aortic second sound, with a loud grade 2 systolic murmur in all areas; and abdomen, protuberant, slightly tense, no palpable organs, and fecal impaction. The neurological examination revealed active tendon reflexes bilaterally. There was extreme weakness in both legs, with hypotonia. The patient did not appear acutely ill.

A roentgenogram of the chest was essentially normal, and urinalysis showed a specific gravity of 1.004, traces of albumin, an occasional hyalin cast, white blood cells, and many bacteria. A blood culture was taken and was reported sterile. A blood cell count showed 575 white blood cells per cubic millimeter, with 90% lymphocytes. The hematocrit value was 33% and the hemoglobin level 9.3 gm. per 100 cc. A throat smear and culture showed beta-hemolytic streptococci, gamma streptococci, nonhemolytic micrococci, and Escherichia coli.

On July 23, the white blood cell count was 600 per cubic millimeter, with no mature neutrophils, and a sternal puncture was done for a bone marrow study. The bone marrow showed complete maturation arrest of the granulocytic series, with only myeloblasts seen. There was an increase in the mononuclear series, such as lymphocytes, plasma cells, and reticular cells. Urinalysis showed a specific gravity of 1.007 and was positive for hemoglobin. Microscopic examination revealed increased cylindruria. The patient showed increased inability to move her legs. There were small areas of ecchymosis in both eyes. A diagnosis of agranulocytosis due to drug reaction was made.

Medical treatment consisted of the intramuscular administration of tetracycline (Achromycin), 200 mg. every four hours; procaine penicillin, 600,000 U.S.P. units once daily; procaine penicillin for aqueous injection, 300,000 U.S.P. units every two hours; and cortisone, initially 200 mg. administered intramuscularly, then 100 mg. every eight hours. The patient was given 40 units of corticotropin (ACTH) with the first dose of cortisone. Because of the decrease in red blood cells, 500 ml. of blood was administered July 23. One concentrated, salt-poor unit of liquid normal human serum albumin (25 gm. albumin in 100 ml.) was also given. The patient's intake and output of fluid was measured, and supportive fluid was administered intravenously.

On July 24, cortisone, 100 mg. three times daily, was given, and on July 25 the cortisone was decreased to 40 mg. every six hours. At this time, clinical jaundice was evident and agranulocytosis of the oral cavity and oropharynx was noted. The abdomen showed moderate distention on the morning of July 26. That afternoon acute pulmonary edema with auricular fibrillation developed, and the blood pressure fell to 60/40 mm. Hg. The patient for the first time appeared critically ill. She was digitalized with lanatoside C (Cedilanid). Oxygen nasally and methoxamine (Vasoxyl) hydrochloride, 1 ml. intravenously and intramuscularly, were administered. There was complete renal shutdown, and the blood pressure failed to rise above 60/40 mm. Hg. In the early morning of July 27, the patient died.

Results of additional laboratory studies during her course in the hospital were as follows. On July 24, total bilirubin level was 5.54 mg. per 100 cc., with direct 3.99 mg. and indirect 1.55 mg., thymol turbidity, 4 units (Shank-Hoagland); cephalin flocculation, negative in 24 hours; serum alkaline phosphatase, 5 Bodansky units; and prothrombin time, 16.9 seconds (control) and 14 seconds. The white blood cell count was 350 per cubic millimeter in the morning and 125 in the afternoon, with 90% lymphocytes in both counts. The hematocrit value was 32% and the hemoglobin level 10 gm. per 100 cc. Urinalysis showed numerous granular casts, 1+ albumin, and 2+ sugar. On July 25, the total bilirubin value was 10.6 mg. per 100 cc., with direct 8.4 mg. and indirect 2.2 mg. The white blood cell count was 450 per cubic millimeter, with 50% lymphocytes; hemoglobin level 8.9 gm. per 100 cc.; and hematocrit value 29%. The nonprotein nitrogen level was 47 mg. per 100 cc. on the morning of July 26. The gross findings at autopsy were pulmonary edema and atelectasis, acute ulcerative colitis, fatty metamorphosis of the liver, and agranulocytosis.

Comment

Apparently most of the ataraxic drugs are capable of depressing the bone marrow when used in sufficient dosages and over long periods of time. The advisability of frequent blood cell counts during the administration of these ataraxic drugs cannot be overemphasized.

Summary

A fatal case of agranulocytosis occurred in a patient on the 48th day of administration of promazine (Sparine). The dosage had been instituted at 100 mg. per day and reached a maximum of 1 gm. per day in four divided doses over a 42-day period.

Improvements in Cancer Survival Rates.—The Connecticut Cancer Record Register has information on 75,494 cancer cases diagnosed from 1935 through 1951. Follow-up information reveals that the outlook for survival is improving for some forms of cancer. Marked increases in five-year survival rates were observed for patients with cancers of the large intestine, rectum, cervix, corpus, prostate and endocrine glands. Both earlier case finding and more effective utilization of available therapeutic technics apparently were factors in increasing the proportion of cancer patients alive five years after diagnosis. Effective use of technics has had a more measurable effect in recent years. Further increase in survival must be predicated on research for better diagnostic and therapeutic methods.—M. H. Griswold, M.D., S. J. Cutler, M.A., and H. Eisenberg, M.D., *The New England Journal of Medicine*, June 7, 1956.

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The following paper was presented at the symposium, "Some Inorganic Elements in Human Nutrition," in Nashville, Tenn., April 4, 1955. This symposium was sponsored jointly by the Nashville Academy of Medicine, the Vanderbilt University School of Medicine, and the Council on Foods and Nutrition. This report is the final of the series, others of which appeared in The Journal *April 21, June 9, Sept. 15, and Nov. 10, 1956.*

PHYSIOLOGICAL BASIS OF POTASSIUM THERAPY

Daniel C. Darrow, M.D., Kansas City, Mo.

Rational treatment of disturbances of the body potassium level is based on the physiology of water and electrolytes. Beginning with Ringer's studies of the effects of electrolytes on the heart, numerous investigations have indicated that the activity of all cells is altered by changes in the concentration of the potassium surrounding the cells. High plasma concentrations exert their most important effect on the heart, because arrhythmia and heart block are produced at plasma potassium concentrations of 8 to 10 mEq. per liter.[1] A flaccid paralysis of skeletal muscle has been observed at high concentrations in some patients with advanced renal failure. The paralysis resembles that seen with low plasma potassium levels except that the electrocardiograms are characteristic of those of patients with potassium intoxication. The high-peaked T waves are the earliest electrocardiographic alterations, but absent P waves, spreading QRS complexes, and more advanced disturbances develop later.

When the potassium concentration in plasma is low, a patient's first complaint is usually lassitude and weakness. The electrocardiograms often show flat T waves that may be inverted. Little evidence of cardiac failure is present in mild deficiency, but when potassium deficiency is severe and prolonged, circulatory failure and myocardial necrosis occur. The skeletal muscles show diminished tone, weakness, and, under certain circumstances, flaccid paralysis identical with that described in familial periodic paralysis. The weakness is usually more pronounced in the lower extremities, but the muscles of respiration may be sufficiently involved to interfere with their functions. The smooth muscles also show decrease in tone, producing intestinal and gastric distention, nausea, occasionally vomiting, and finally paralytic ileus. Indeed, potassium deficiency must always be considered a possible cause of paralytic ileus, although other disturbances produce the same picture. The paralysis in both smooth and skeletal muscles is apparently caused by a failure of myoneural conduction that is readily reversed by an increase in serum potassium concentration. Potassium also alters other neural reactions. Certain patients with low serum calcium levels do not have tetany when the serum potassium level is low, but tetany is manifest when potassium concentration rises to normal.[2]

In a study made in 1945, the implications of the changes in muscle composition observed in rats were discussed.[3] On the basis of these experiments it was possible to deduce many of the clinical states of potassium deficiency in patients, which subsequent studies have demonstrated. The quantitatively important alterations in potassium in the body are accounted for by changes in potassium in muscle. There is no evidence of increased storage of potassium in cells except for the slight rise that accompanies an increase in serum concentration. This increase in cell potassium levels does not persist when normal plasma concentrations are restored. A decrease in the muscle potassium level may be great, but it is not necessarily accompanied by decreases in serum concentrations. As a result of diets low in potassium, muscle potassium levels may decrease to half the normal value.[4] Usually about two-thirds of the decrease is replaced by an increase in intracellular sodium. This is equivalent to a loss of about 25 mEq. of potassium per kilogram and an increase of intracellular sodium of about 17 mEq. per kilogram of body weight. Clinical studies indicate that essentially the same changes occur in patients. Evaluation of the clinical states is closely related to the experimental studies.

The potassium content of the cell is primarily dependent on the cell's structural and metabolic integrity. It is not known by what mechanism the cells maintain a high concentration of potassium and a low concentration of sodium while surrounded by extracellular fluids with a low potassium and a high sodium concentration. Water is exchanged rapidly between extracellular and intracellular fluids, but the rate of net exchange of sodium and potassium is somewhat limited. It is clear that potassium leaves and sodium enters the cells when cellular metabolism ceases. A more limited exchange of this type probably occurs when metabolic processes are impaired. Anoxia and insulin deficiency are examples of this type of altered exchange that can be reversed.

The therapeutic administration of potassium first requires treatment that restores normal cellular metabolism as far as this is possible. In shock and dehydration, replacing deficits of water and extracellular

---

From Children's Mercy Hospital and the Department of Pediatrics, University of Kansas.

electrolytes is the first step in treating potassium deficiency. Although restoration of extracellular water and electrolytes is the most important means of correcting the circulatory failure of dehydration and deficit of sodium and chloride, transfusions make this therapy definitely more effective in experimental animals and patients. In hemorrhagic and oligemic shock, transfusions are essential. Likewise, insulin is necessary in diabetic coma in order to facilitate the uptake of potassium by cells depleted of this ion. Administration of water, sodium, and chloride is equally important in patients who have suffered large losses; administration of oxygen is indicated in some anoxic patients. These measures that restore cellular metabolism should be carried out before the administration of potassium is started.

Rapid restoration of cellular metabolism in a patient with large cellular deficits of potassium may lead to rapid transfer of extracellular potassium to the cells. Consequently, symptoms of low concentration of potassium in serum are likely to develop rapidly. If renal function is good, the administration of potassium may be started early, but it should be started slowly and in anticipation of the decrease in serum potassium concentration. Owing to the particularly rapid restoration of cell metabolism in diabetic coma, frank symptoms of potassium deficiency are especially likely to develop in patients treated without potassium at the time when the effects of insulin appear. Patients in alkalotic states with potassium deficiency are also likely to develop symptoms of hypokalemia because alkalosis increases the tendency to transfer potassium from extracellular to intracellular fluids. In diabetic coma, skeletal muscle weakness and paralysis have been observed, whereas in alkalosis, intestinal distention, vomiting, and paralytic ileus are more frequent. In other types of acidosis with potassium deficiency, a decrease in serum potassium concentration during treatment is likely to develop more slowly. The reason for this is that, initially, the serum potassium concentration is likely to be somewhat high, and transfer of potassium from extracellular to intracellular fluids is retarded by acidosis. If sodium bicarbonate or its equivalent is given to increase rapidly the plasma bicarbonate level, a decrease in serum potassium concentration is likely to be accelerated.

These statements are based on clinical observations and experimental studies. When muscle is placed in Ringer's solution with a given potassium concentration, a high pH of this solution leads to transfer of potassium to the cells while a low pH produces the opposite effect. This observation has been confirmed in nephrectomized dogs receiving injections of ammonium chloride or sodium bicarbonate. In otherwise normal dogs, production of metabolic acidosis and alkalosis demonstrates an inverse relationship between serum pH and serum potassium concentration that is not explained by a change in total body potassium.[5] In dogs previously depleted of potassium, the same inverse relationship is manifest; however, the serum potassium concentrations remain somewhat lower. As would be anticipated, potassium tends to enter the cells as serum potassium concentration rises, and vice versa. This reaction is more or less independent of the shifts accompanying changes in pH.

The clinical implications of these observations are reasonably clear. Serum potassium concentration reflects the changes in serum pH and the concentration of potassium in cells. The serum potassium concentration is likely to be low in alkalosis even if the cell potassium level is relatively normal but especially low when cellular potassium deficiency is present. In alkalosis, serum potassium concentration is not likely to be high unless renal function is impaired and the cell potassium level is relatively normal or unless disturbances in cellular metabolism have developed. In acidosis, serum potassium concentration is likely to be normal or high despite cellular deficits. Low serum potassium concentrations in acidosis usually indicate considerable deficits of intracellular potassium. Disturbances in cellular metabolism and renal function must also be considered in evaluating potassium concentration in acidosis.

Renal response to respiratory changes in acid-base equilibrium tends to exaggerate the changes in plasma concentration produced by the alteration in carbon dioxide tension. In respiratory acidosis, carbonic acid donates hydrogen ions to buffers, thereby forming undissociated weak acids and raising serum bicarbonate. The kidneys further increase bicarbonate concentration by excreting hydrogen ions. The process is, in effect, an exchange of plasma chloride for bicarbonate of the glomerular filtrate. In this process, the muscle potassium level is well maintained.[6] In respiratory alkalosis, the exchange for sodium of hydrogen ions freed from undissociated weak acids decreases plasma bicarbonate. The kidneys exaggerate the decrease in bicarbonate by retaining hydrogen ions. This is accomplished by exchanging plasma bicarbonate for chloride of the glomerular filtrate. It is not known whether serious deficits of potassium develop in respiratory alkalosis. In any case, replacement therapy is seldom indicated, since the kidneys readily restore normal body electrolyte balance when carbon dioxide pressure becomes normal.

In metabolic acidosis, the normal kidneys tend to restore normal extracellular concentrations if sufficient sodium, potassium, chloride, and water are available. The fundamental operation that restores a low serum bicarbonate value is the excretion of hydrogen ions. Experimental acidosis caused by administration of hydrochloric acid to dogs is corrected first by excretion of the excess of chloride with sodium and then potassium. The excess of chloride is reduced, but deficits of sodium and potassium are likely to develop; hydrogen ions are not excreted, and bicarbonate concentration is not restored. Only after 1 or 2 days are sufficient ammonium ions formed to conserve sodium and potassium and to excrete hydrogen ions effectively. These observations indicate that in metabolic acidosis abundant sodium and potassium are required for renal compensation. The experiments also show that deficits of potassium as well as of sodium are likely to develop. The changes in body composition are not confined to extracellular fluids.

In metabolic alkalosis, the normal kidneys also tend to restore normal plasma concentrations if sufficient sodium, potassium, chloride, and water are available. The fundamental operation is retention of hydrogen ions. This is accomplished, in effect, by excretion of bicarbonate or organic acids with sodium and potassium. Metabolic alkalosis is usually accompanied by a relative or absolute excess of sodium in the body. Accordingly, the renal compensation is only likely to produce deficits of potassium. The course of events is well illustrated by experiments on rats given large loads of sodium bicarbonate and variable amounts of potassium chloride.[7] Alkalosis, which developed only when the intake of potassium was low, was always accompanied by a decrease in muscle potassium and an increase in intracellular sodium. Apparently excretion of a certain amount of potassium is necessary to preserve plasma chloride concentrations and to prevent alkalosis. These observations fit in well with clinical experience, which shows that metabolic alkalosis is not corrected despite an abundant excretion of sodium and chloride when potassium deficiency develops.[8]

The plasma bicarbonate concentration varies directly with intracellular sodium and inversely with the muscle potassium level in experimental rats. Clinical observations fit in well with these observations if due attention is paid to the experimental conditions. Metabolic acidosis was produced by removal of sodium bicarbonate by peritoneal exchange and maintenance of rats on a diet containing abundant potassium and chloride but no sodium. Metabolic alkalosis was produced by peritoneal exchange of body chloride for bicarbonate. The rats received a diet abundant in sodium and potassium but no chloride. Potassium deficiency was produced by injections of desoxycorticosterone acetate in rats on a low-potassium diet with an abundance of sodium chloride. Sufficient time was allowed in all experiments to permit renal adjustment to the experimental conditions. Deficit of chloride and potassium resulted in essentially the same changes in the muscle and serum, that is, metabolic alkalosis, high serum bicarbonate values, and low chloride concentrations with low muscle potassium and high intracellular sodium levels. Deficit of sodium bicarbonate resulted in metabolic acidosis and low intracellular sodium and high muscle potassium concentrations. Changes in the metabolic alkalosis and potassium deficiency are frequently met in clinical medicine; however, metabolic acidosis is not often seen in patients when an abundance of potassium is available.

Protein milk produces metabolic acidosis accompanied by retentions of potassium and chloride.[9] Muscle potassium concentration is probably high in such cases. Acidifying salts may have a similar effect if the intake of potassium is high. Usually the losses of electrolyte, which produce metabolic acidosis, result in deficits of potassium as well as in deficits of sodium and chloride. Diminished intake of potassium and losses of this ion in diarrheal stools produce considerable deficits of potassium, sodium, chloride, and water.[10] In addition to the losses of bicarbonate with sodium in the stools, the extracellular bicarbonate level is reduced by loss of bicarbonate with potassium in the stools. The cellular deficit of potassium is partially replaced with extracellular sodium. Similar changes in body composition occur in diabetic coma. Organic acids are excreted with potassium as well as with sodium. Although some of the reduction in plasma bicarbonate is accounted for by displacement of bicarbonate by ketone acids, a major part is usually caused by excretion of bicarbonate with sodium and potassium.

The importance of the changes in body composition is brought out in studies of experimental alkalosis with potassium deficiency in rats. The exchange of ions between extracellular and intracellular fluids, as well as by renal regulation, explains the restoration of normal acid-base equilibrium by administration of either potassium chloride or potassium bicarbonate with no external source of sodium.[7] With the administration of potassium chloride, the exchange between extracellular and intracellular fluids may be depicted as follows: 3 KCl is added to the extracellular fluids; 3 K^+ enter the cells in exchange for 2 Na^+ and 1 H^+. The H^+Cl^- reacts with $NaHCO_3$ to form CO^2, H^2O, and Na^+Cl^-. Consequently, bicarbonate concentration is restored without excretion of bicarbonate by the kidneys being required. With administration of potassium bicarbonate, the same exchange at the membrane takes place; 2 $NaHCO_3$ and 1 H_2CO_3 are formed in extracellular fluids. Bicarbonate must be excreted by the kidneys in order to restore normal acid-base equilibrium. Chloride concentration rises (despite no external source of chloride) because extracellular volume decreases, as indicated by a decrease in body weight.

The foregoing description of the exchange between extracellular fluids and muscle indicates that the reverse exchange occurs during the development of metabolic alkalosis. In other words, the muscle cells in metabolic alkalosis have received an excess of hydrogen ions that is as great as the deficit of hydrogen ions in extracellular fluids. The excess of hydrogen ions probably produces little change in cell pH since protons from the hydrogen ions would form undissociated weak acids or possibly weak bases from amino compounds. Potassium is apparently necessary for the renal compensation of metabolic alkalosis. This observation is confirmed in those patients with metabolic alkalosis who fail to respond to administration of saline solution unless potassium is also available.[11]

Metabolic acidosis has not been studied in similar detail; however, it is clear that large doses of sodium bicarbonate are required to restore bicarbonate concentration in metabolic acidosis, not because the deficits of sodium bicarbonate are this great in extracellular fluid but because, as the result of a potassium deficiency, a large part of the injected sodium ion enters the cells in exchange for the hydrogen ion. Since the extent of this transfer cannot be predicted in patients, the calculation of the dose of sodium bicarbonate required to restore acid-base equilibrium has no sound physiological basis. The cellular deficit of cations should be replaced with potassium. In general, acidosis accompanied by dehydration should be treated by replacing extracellular water and electrolytes by a solution resembling extracellular fluids, such as Hartmann's Ringer lactate. Simultaneously, or as soon as renal function and cellular metabolism are adequate, potassium should be given in amounts that adequately cover normal expenditure and replace some of the deficits. It is seldom necessary to give more bicarbonate than that contained in this solution; however, 4 mM. of sodium lactate per kilogram of body weight (25 ml. of 0.16 M) may safely be given in severe acidosis of this type.

Schwartz and Relman[12] have described persons with severe potassium deficiency that resulted from repeated use of cathartics. These patients did not develop alkalosis. The renal function was altered; hyposthenuria and moderate reduction in glomerular filtration were demonstrated. Renal function did not return entirely to normal over a period of several months. The authors postulated that prolonged potassium deficiency produces renal changes that are not rapidly reversed. The renal disturbances developing in some patients under prolonged Sippy treatment may be of this type.

Schwartz has reviewed the literature on potassium in relation to the kidneys.[13] The excretion of potassium increases when serum concentration of this ion increases. Both acidosis and alkalosis increase potassium excretion; administration of acetazolamide leads to prompt excretion of potassium. Urine with a high level of sodium usually has a high potassium level. The mercurial diuretics produce alkalosis that may or may not be accompanied by deficits of potassium. Desoxycorticosterone, aldosterone, cortisone and other corticosteroids, adrenotropic hormone, and activation of the adrenal cortex increase urinary potassium levels. When oliguria develops in renal failure or when extrarenal factors such as shock and dehydration are present, potassium tends to be retained and toxic levels may be reached. Nevertheless, potassium excretion is usually well maintained in advanced renal insufficiency as long as the urine volume is high. Indeed, symptoms of potassium deficiency have resulted from renal losses in some patients with hyposthenuric renal insufficiency.

The stools normally contain moderate amounts of potassium. Losses of potassium in patients with infantile diarrhea are as great as 17 mM. per day as compared to 2 mM. per day in healthy infants. Stool losses and decreased intake are largely responsible for potassium deficiency in diarrhea. In one study, stool concentration of potassium was reported to be about 57 mEq. per liter in fed patients; during the recovery of patients not fed, the potassium concentration in stools was about 40 mEq. per liter.[10] One patient with voluminous stools containing a large quantity of sodium and chloride was reported to be excreting only 6 mEq. of potassium per liter. When isotonic sodium chloride solution is placed in the colon, potassium concentration rises to about 40 mEq. per liter as sodium chloride and water are absorbed.[14] This finding suggests that the loss of potassium will be high if watery stools remain long in the colon but low if the fluids from the small intestine are rapidly passed through the colon. As was pointed out by Gamble,[15] death from diarrhea may be considered to result from accumulating deficits. It can be calculated that serious water deficits appear first when there is no replacement. If water is restored, deficits of sodium and chloride become serious after only a slightly longer period. If water, sodium, and chloride are restored, potassium deficits are serious after a slightly longer period.

Treatment of infantile diarrhea involves the restoration of water and electrolytes as well as the restoration of normal stools. In a report mentioned earlier, the average deficits were 125 gm. of water, 9 mM. of sodium chloride, and 12 mEq. of potassium per kilogram of body weight. A postacidotic state after the treatment of infantile diarrhea was described by Rapoport and associates.[16] A decrease in serum concentration of phosphorus, potassium, and calcium was frequent, and failure to recover was attributed to hypocalcemic tetany in many cases. Although I have observed hypocalcemia occasionally in patients recovering from infantile diarrhea, this finding has been rare when potassium as well as sodium salts have been used. A possible explanation of the contradictory experiences is that in normal rats administration of sodium chloride and sodium bicarbonate does not produce hypocalcemia, but the same salts reduce serum calcium concentration in rats previously depleted of potassium. Potassium deficiency alone does not reduce calcium concentration. It is believed that a disturbance in the regulation of extracellular calcium concentration develops when sodium concentration is rapidly increased in the presence of potassium deficiency. To the extent that hypocalcemia explains the postacidotic state, this hypothesis indicates that tetany of this type is an iatrogenic disorder resulting from the administration of too much sodium bicarbonate to patients deficient in potassium. Presumably, early administration of potassium prevents this disturbance.

The association of alkalosis and profuse watery stools in congenital alkalosis with diarrhea is a rare condition.[17] The fluid in the small intestines is normal and food is well absorbed; however, the stools contain large volumes of water, more chloride than sodium, and a considerable amount of potassium. The deficit of chloride accompanying marked elevation of the serum bicarbonate concentration is explained by stool losses, since the urine is practically devoid of chloride.

Prolonged fasting may induce marked alkalosis and potassium deficiency. Some patients with anorexia nervosa exhibit this phenomenon.

The treatment of potassium deficiency is essentially the same in persons of all ages. Deficits should be estimated in milliequivalents per kilogram of body weight and are unlikely to be greater than 17 mEq. per kilogram. It is usually safe to give 3 mEq. per kilogram per day together with the appropriate amounts of fluid to cover normal and abnormal expenditure and to restore initial deficits of sodium and chloride. The total fluid requirements in infants are sufficient so that this amount of potassium can be given at a concentration of 25 mEq. or less per liter. In adults, the appropriate amounts of fluid are such that concentration of potassium would have to be 60 mEq. per liter in order to supply this amount. It is desirable not to exceed a concentration of 40 mEq. per liter of fluid injected into the veins. The estimated amount of potassium for 24 hours may be injected more rapidly but not in less than 4 hours. For severe deficiency, somewhat larger doses may be given, but their effects should be carefully observed by electrocardiography, measurement of serum concentrations, and clinical observation of the patient. The amounts of potassium that can be given safely are such that it takes 4 to 6 days to replace large deficits.

Total fluid requirement should be estimated as 150 ml. per 100 calories metabolized. This practice takes into account the different rates of expenditure of water that accompany different metabolic rates in infants and adults and other factors altering total metabolism. Total metabolism is usually about 1,000 calories per square meter of body surface, and fluid requirement about 1,500 ml.; however, in newborn infants who have not been fed, the total metabolism is low—about 60% of the usual amount per square meter. The fluid requirement after operations in the newborn infant is not low per unit of metabolism. It is lower than the usual amounts calculated per kilogram of body weight or per unit of surface area.

The expenditure of potassium when all fluids are given parenterally varies from 1 to 3 mEq. per 100 calories metabolized—usually 20 to 30 mEq. per square meter per 24 hours. Even when there is no deficit of potassium, these amounts should be given in order to prevent deficiency.

A suitable mixture for replacement of fluid removed by gastric suction is sodium chloride solution of about one-half isotonic strength and 40 mM. of potassium chloride (3 gm.) per liter in a 2.5% dextrose solution. In most cases of metabolic alkalosis, the deficits of sodium chloride are replaced by 20 to 40 ml. per kilogram of isotonic sodium chloride solution. To this, the therapeutic amount of potassium chloride should be added.

Often electrolyte therapy can be oral when food cannot be taken. The requirements of water, sodium, chloride, and potassium are the same as when all fluids are given parenterally. This means that the normal expenditure of 3 mM. of sodium chloride and 2 mEq. of potassium per 100 calories metabolized would be given in 150 ml. of water. It is advisable to prescribe definite mixtures such as 1 gm. each of sodium chloride, sodium bicarbonate, and potassium chloride in a liter or quart of a 5% glucose solution. Such a solution has made it possible to handle practically all cases of mild infantile diarrhea without administering fluids parenterally. Use of the mixture permits the period of parenteral administration of fluid to be shortened. The solution has been useful in the postoperative care of infants and children and is appropriate in both acidosis and alkalosis; there is no reason why it should not be effective in similar conditions in adults. I have found it more convenient and safer to use a mixture of definite composition manufactured for this purpose (Lytren). This mixture contains electrolytes sufficient to replace moderate deficits of sodium, chloride, and potassium and to provide for a moderate increase in expenditure. Such mixtures should be prescribed in definite amounts suitable to cover normal water expenditure. Additional water may then be added when expenditure of water is high.

Summary

Potassium deficiency is likely to develop in acidosis or alkalosis when there is prolonged diarrhea or prolonged parenterally given fluid therapy without potassium. Fasting may induce deficiency. The cortical hormones increase the amount of potassium in the urine. Renal function is altered by alkalosis so that potassium deficiency is likely to appear. Potassium deficiency alters renal function so that alkalosis appears or persists. The excretion of loads of anions with potassium is part of the cause of potassium deficiency in acidosis. Potassium intoxication may develop when oliguria occurs in renal disease or when renal function is impaired by extrarenal factors such as shock or dehydration. Administration of potassium with suitable mixtures of sodium, chloride, and glucose in water is relatively safe if certain rules as to dose and rate of administration are followed. Renal function should be good and the circulatory failure of shock overcome. The chief contraindication to potassium therapy is renal failure with oliguria and untreated adrenal insufficiency.

COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs described here and in subsequent editions of New and Nonofficial Remedies are based on the evaluation of available scientific data and reports of investigations. Applicable commercial names for preparations of evaluated drugs are listed at the end of monographs and parenthetically in the text of supplemental statements; additional commercial names of which the Council is informed will be included with subsequently published supplemental statements and annual editions of New and Nonofficial Remedies. H. D. Kautz, M.D., *Secretary.*

Topical Use of Prednisolone

The Council has evaluated the topical use of prednisolone (Meti-Derm) for the local management of dermatoses susceptible to gluco-steroid therapy. On the basis of currently available evidence, the Council concluded that the drug, incorporated in a suitable dermatological vehicle, is effective in ameliorating cutaneous manifestations of acute and chronic dermatoses that have an allergic or inflammatory basis and are associated with pruritus. These include such conditions as contact dermatitis, various forms of atopic dermatitis, seborrheic dermatitis, nonspecific anogenital pruritus, and lichenified pruritus. No systemic side-effects have been observed after absorption of the drug. In some cases, sensitization or irritation may follow its topical application, particularly to an eroded skin; however, this is more likely to be caused by the base in which it is incorporated than by prednisolone itself. The drug should not be applied to infected areas of the skin.

For topical administration, a cream containing 5 mg. of prednisolone per gram is applied to the affected areas of the skin three or four times daily.

The Council voted to amend New and Nonofficial Remedies accordingly to describe the use of prednisolone by the topical route.

Schering Corporation cooperated by furnishing scientific data to aid in the evaluation of the topical use of prednisolone.

Intramuscular Use of Crystalline Trypsin

The Council has evaluated the intramuscular use of an oil suspension of crystalline trypsin (Parenzyme) for the treatment of thrombophlebitis, phlebothrombosis, ocular inflammations, traumatic wounds, and varicose and diabetic leg ulcers. Currently available evidence suggests that many patients respond favorably to the drug. While few controlled clinical studies have been published to date, other reports indicate that a majority of patients refractory to standard modalities obtain beneficial results from trypsin administered intramuscularly. It should not be given in lieu of anticoagulants but as adjunctive therapy for reduction of inflammation and edema at the site of phlebitic processes.

Crystalline trypsin in oil produces pain and induration at the site of intramuscular injection in a sizable proportion of patients; however, the incidence of these side-effects may be appreciably reduced if a thoroughly dry and sharp needle is employed. Febrile reactions and leukocytoses, resembling those produced by parenteral administration of foreign protein, are rare. Occasionally, angioneurotic edema, hives, and urticaria occur. The drug is contraindicated or should be used with extreme caution in patients with renal or hepatic damage, blood clotting abnormalities, or hemorrhagic states. Its ultimate safety after long-term intramuscular therapy is not as yet completely determined.

Crystalline trypsin in oil is administered by deep intragluteal injection, alternating sites and buttocks. Prior to administration, sensitization tests should be performed on patients with a history of hypersensitivity. Doses of 2.5 to 5 mg., one to four times daily for three to eight days, have been administered and should be considered tentative. Dosage must be individualized and depends on the severity of symptoms and the degree of response. Adequate precautions against accidental intravenous injections should be exercised.

The Council voted to amend New and Nonofficial Remedies accordingly to describe the intramuscular use of a suspension of crystalline trypsin in oil.

The National Drug Company cooperated by furnishing scientific data to aid in the evaluation of the intramuscular use of crystalline trypsin.

MEDICINE AT WORK

CHEER UP! MORE HOSPITALS ARE SAYING SO

"If you are a maternity case you have an extremely healthy ailment. An old lady we know told her expecting granddaughters that the whole army and navy came that way."

◆

"We use 146,000 clean diapers (a year)—to dry them at the same time we would need a 90-mile clothesline (stretching from Philadelphia to New York.)"

◆

"A mechanic fixes machinery. A doctor fixes people . . . Some doctors have boys and girls of their own. Doctors love children and they work hard to make sick children well again."

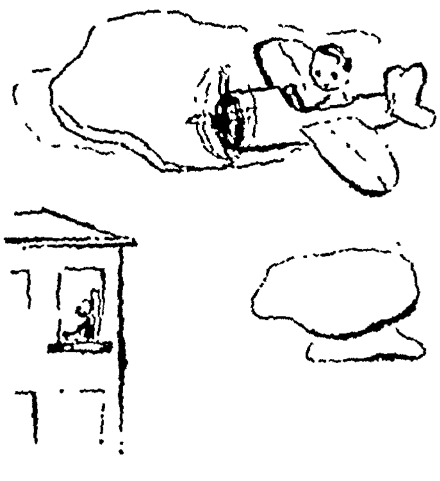
◆

"Lenox Hill is a nonprofit hospital . . . and, you will hardly believe it, in a way we are proud of losing money. It proves that we are not using a hospital bed as a milk cow."

◆

(*In answer to how many times a day a buzzer rings in the hospital*): "5,000 times. Of course 398 times are on account of old Mrs. B. . . . who wages real push-button warfare against us."

Folksy comments like these are greeting millions of hospital patients every year in sprightly booklets liberally sprinkled with cartoons, photos, and artistic use of color. The frightened child facing an operation in New York City's Memorial Center relaxes in calm curiosity of "the x-ray camera that takes a picture of the inside of your body." The depressed tubercular in Philadelphia General Hospital cannot suppress a smile at the caricature in his booklet of two patients shooting dice beside coins and bills on the ward floor—under the caption: "Gambling is not permitted in the hospital."



Adorning the cover of the Palo Alto, Calif., Hospital's patient information booklet is a sketched physician-stork standing atop a chimney on one leg and peering at a watch held in the other. Inside the pamphlet is a series of questions and answers for expectant mothers. Sample: "Q. When do I see my husband again? A. After the nurses finish preparing you for delivery, he will be called from the Heir Port."

Booklet Success Is Spreading

This sort of light informative touch has been so successful in recent years that many hospital administrators, physicians, nurses, and patients find themselves wondering why it has not been done before on a large scale. The Franklin Square Hospital in Baltimore not long ago began distributing instructional sheets for the patient (one sheet prepares him for a basal metabolism test—under the sketch of a sprawling hound and the heading: "Let's see how lazy YOU can be").

Hospital Administrator Sanford Kotzen questioned doctors who had enjoyed privileges at several hospitals—to verify that the patient information sheets were eliminating interruptions in preoperative and prediagnostic routine. One physician told Kotzen: "This is the kind of thing hospitals should have done long ago." Another said: "They should have something like these in all hospitals."

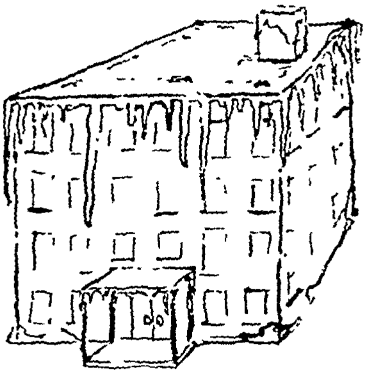
Already, the American Hospital Association notes "an increasing interest" among the nation's 7,000 hospitals in publishing informational material for the 21 million patients who go through their doors each year. At last report, 26% of the hospitals were offering this service—ranging from 11% of the proprietary general and special short-term hospitals to 50% of all tuberculosis hospitals in the United States. Now, says the A. H. A., "patients' booklets are used regularly more than any other" hospital publications, including employe information sheets, house organs, and annual reports.

Not long ago in a survey, the nearly 2,000 hospitals that publish information for patients were asked to report response to their booklets. Not one comment was unfavorable. The praises included: "Patients like it and doctors feel it helps the patient understand," and "a very valuable technique in the rapid orientation of the patient." All agreed that the price of publication was well worth the long-run public relations and immediate-cooperation value received.

Examples of effective booklets range from a two-fold sheet costing less than a penny a copy (and containing hospital rules, visitors hours, rates, cost of guest meals, and list of staff members and credentials) to a 30-page slick pamphlet with pictures and color, costing 12½ cents a copy (and carrying complete information about the hospital with line drawings on each page). Says the A. H. A.: "There is no reason why an economy-minded administration could not mimeograph essential information in a neat and readable form."

Cold Versus Warm Treatment

For years, many a doctor has been concerned with how conditions in a few "cold" hospitals have chilled tensely his otherwise warm patients at a crucial time when preoperational relaxation is so important. The physician knows that when a hospital informs his patients of the things and routine around them, and what is happening to them and why, the resulting cooperation makes for better convalescence and often a shorter stay in the hospital. At the same time, the hush-hush of the medieval medical approach is eliminated by dispelling a sometimes popular notion that medicine lies in a realm of deep dark secrets.



The 32-page illustrated handbook for patients in the new Hunterdon Medical Center in Flemington, N. J., stresses medical care as "a team problem, too complicated for any single physician to provide." That note is echoed by the University Hospital at Ann Arbor, Mich., in a booklet that lists the many hospital people who contribute to the patient's comforts.

The booklet of Boston's Peter Bent Brigham Hospital carries this reminder: "Mr. Patient sees the doctor, the nurse, the food he does not want, the early morning call, the cashier to whom he pays his bills." Then, taking the opportunity to show what today's sharply higher hospital bills are paying for, the booklet continues: "But he does not see the pharmacist, the sterile supply room, the medical record library, the instrument repair shop, the surgical supply room . . . the operating room and its costly equipment . . . the expert radiologist . . . the blood bank . . . the costly laboratory equipment and the trained personnel . . . the dietary department and the gleaming modern kitchens . . . the laundry . . . the linen and supply rooms . . . the elaborate power plant . . . the window cleaner, the refrigeration mechanic, the steam-fitter, the plumber, the carpenter, the painter, the elevator mechanic . . ."

There is greater cooperation when the patient understands what rules in the book he is expected to follow. Nurses have an easier time of it because many questions they would be asked are answered in print. All this conditioning expands the doctor-patient atmosphere of confidence and cordiality so essential to medical counseling.

Information booklets are kept in some doctors' offices so that the prospective patient can prepare for a hospital stay. This is particularly effective in maternity cases. The Presbyterian Hospital in Chicago puts out a 32-page booklet that is fine art with its gently stylized sketches of mother and child and with its easily understood advisory text covering suggested diets and also conditions before, during, and after birth. (At one point, it is stated in the booklet: "At no time are you to substitute this booklet or any other for your doctor. Nothing can take the place of the careful supervision you will receive from your physician.")

Personal Approach Does It

Most of the pamphlets are written with the personal approach. The Medical College of Virginia Hospital in Richmond asks its patients to grade the hospital in a back-page quiz on food, services, and suggestions for improvement. The University (of Michigan) Hospital tells its story in the words of a "typical" woman patient facing problems and questions encountered by any patient. Dr. Jack Weatherly, as staff psychiatrist in the Veterans Administration Hospital at Gulfport, Miss., writes that the psychiatric patient often responds favorably to the use of personal pronouns in the booklet text: "You will be seen soon by your ward doctor and, later, when your own case doctor sees you, you can spend as much time as you need to talk over your problem."

"The pen is mightier than the scalpel," says the A. H. A. in urging more hospitals to publish information for patients. The association recommends that the writing be done by people who have the same fears, confusion, and anxiety as patients—if possible, by people not in the hospital field. They say this advice has brought about the current crop of humor, lighthearted copy, and touching line drawings among the booklets being published today in the U. S. (A straightforward approach is used for psychiatric patients, since they might easily misconstrue efforts at wit and cheery pep talks.)

You can still become a patient in a hospital that is devoid of the personal touch. At some places, you can still gaze through the institutional atmosphere at things and people sterile and antiseptic—only occasionally seeing also your own physician as personification of familiar warmth and understanding. But today, as never before, you will find this picture of hospital life diminishing in the United States. Many physicians would like to see it vanish completely.

VIRAL ETIOLOGY OF CANCER AND LEUKEMIA?

GUEST EDITORIAL

Ludwik Gross, M.D.

During the past decade the concept of viral etiology of cancer and allied diseases has gained considerable momentum. Experimental data began to accumulate pointing more and more to the possibility that many, if not all, malignant tumors may be caused by viruses. Thus, a large number of malignant tumors of different morphology and in different species of animals could be transmitted from one host to another by filtered extracts. At this time, most of the common tumors in chickens, such as the various forms of leukemia and sarcoma, have been found to be transmitted by filtered extracts. The natural epidemiology of chicken lymphomatosis through the embryonated eggs has also been established.[1] In some instances, among newly hatched chicks, the transmission may be air-borne.

The most impressive recent advances, however, in the field of viral etiology of tumors have been accomplished in mice. The fundamental discovery of Bittner[2] in 1936, showing that a certain form of breast carcinoma in the mouse is due to a virus that is transmitted in the milk from healthy (at the time of transmission) carrier mothers to their suckling offspring, could be considered the turning point in the history of modern cancer research. Fifteen years later, in 1951, mouse leukemia, a disease clinically and morphologically strikingly similar to that occurring in humans, was demonstrated[3] to be caused by a filterable virus. The use of newborn animals proved to be essential for successful transmission of the cell-free leukemic agent in mice. Shortly afterward it was found[4] that, when filtered extracts prepared from leukemic mice were inoculated into newborn animals of certain susceptible nonleukemic strains, some animals developed leukemia, whereas others developed parotid gland carcinomas and/or subcutaneous fibromyxosarcomas. These results have been recently confirmed by Woolley,[5] at the Sloan-Kettering Institute in New York. When, later, filtered extracts were prepared from parotid tumors, or sarcomas, and inoculated into newborn mice, either leukemia, or parotid tumors, and/or subcutaneous sarcomas developed. Similarly, when Graffi and co-workers[6] in Germany inoculated filtered extracts prepared from a transplanted mouse mammary carcinoma into newborn mice, a high percentage of the injected animals developed typical generalized leukemia. The question immediately arose whether one single virus may be able to induce leukemia, parotid gland tumors, subcutaneous sarcomas, or carcinomas, or whether the leukemic extracts contained a mixture of distinct, though possibly related, oncogenic agents. This question, which is of fundamental importance, has not yet been answered.

In further experiments it was demonstrated[7] that carrier mice of leukemic strains, earmarked to develop leukemia at middle age, even though in apparent good health when young, transmit the virus to their offspring. This transmission occurs not through the milk, as in the case of mammary carcinoma, but directly through the embryos, from one generation to another. Mouse leukemia, as chicken lymphomatosis, appears to be, therefore, an egg-borne virus disease. In more recent studies it has been shown that the mouse leukemia virus is a spherical particle less than 70 mμ in diameter, which can be visualized in an electron microscope,[7] and that this agent is present in various organs of the carrier animals, and in leukemic tumors and blood plasma of leukemic mice.

In all these experiments, it was necessary to inject newborn mice, only a few hours old, in order to induce, with cell-free extracts, leukemia, parotid gland tumors, or sarcomas. It appeared, therefore, that the use of an animal not more than a few hours old was essential for the successful transmission of these oncogenic agents. When, however, Friend,[8] at the Sloan-Kettering Institute in New York, inoculated cell-free extracts, prepared from a transplanted Ehrlich ascites mouse carcinoma, into newborn Swiss mice, some of the inoculated mice developed generalized leukemia 14 months later; one of these leukemias, a myelogenous form, proved to be transmissible by filtered extracts into adult Swiss mice.

There may exist, therefore, different mouse leukemia viruses, some transmissible to newborn hosts only, others to adult hosts as well. Beard[9] and his associates

---

Chief, Cancer Research Unit, Veterans Administration Hospital, Bronx 68, N. Y.

at Duke University made similar observations in their studies on chicken leukemia: whereas chicks less than 3 days old had to be used for inoculation with the myeloblastosis virus, young adult chickens could be inoculated with the virus of erythroblastosis. Although these two viruses are indistinguishable in electron micrographs, representing spherical particles about 120 m μ in diameter, they induce distinct forms of chicken leukemia.[9]

These recent developments in experimental cancer research add significantly to the older experiments in which various tumors in chickens, rabbits, frogs, and mice have been transmitted by filtered extracts. In humans thus far only warts and papillomas have been found to be transmissible by filtered extracts. By analogy, however, it is quite apparent that many other human tumors may be caused by viruses. It is entirely possible that most, if not all, malignant tumors, not only in animals but also in humans, are caused by filterable viruses. Many of these viruses may be transmitted from generation to generation,[7] remaining in a latent form harmless for their carrier hosts. Now and then, however, prompted by some obscure activating factors (some of them physiological, such as metabolic or hormonal, others extrinsic, such as chemical poisons or ionizing radiation), these hitherto dormant viruses may change into tumor-producing pathogens. Such "accidents" may happen only occasionally, separated by several generations of healthy carriers.[7]

Should this concept prove to be true, oncogenic viruses could be compared to temperate bacteriophages, transmitted from one generation to another in lysogenic bacterial hosts, only very occasionally killing some of their carriers. This concept would throw a different light on the carcinogenic action of certain chemicals as well as the development of leukemia in radiologists and in population groups exposed to ionizing radiation. It would also explain the striking, though rare, reports of familial incidence of cancer and leukemia in humans.

ANNUAL CONGRESS ON MEDICAL EDUCATION AND LICENSURE

At the Congress on Medical Education and Licensure scheduled to be held at the Palmer House, Chicago, February 10-12, 1957, the Council on Medical Education is planning its program to deal with current problems of widespread interest in medical education.

The program on Sunday morning, February 10, will be devoted to a conference on Graduate Medical Education for General Practice—1957, which will be co-sponsored by the Advisory Board for Medical Specialties and the Council. This conference will be introduced by two background statements, one presenting the role of undergraduate medical education today and the other presenting the concept of general practice regarding adequate graduate medical education in preparation for general practice—1957. These two background papers will be followed by a series of short, clean-cut presentations of what should constitute graduate medical education for general practice today as seen from the point of view of (*a*) internal medicine, (*b*) pediatrics, (*c*) surgery, (*d*) obstetrics and gynecology, and (*e*) psychiatry. Ample time will be permitted after these presentations for discussion from the floor, with the speakers acting as a panel. It is hoped that this conference will aid in better clarification of the graduate needs in preparation for general practice—1957, rather than their interpretation in the setting of some years ago. This should be an interesting and valuable conference for all concerned with internship and residency training programs in both specialty and general practice.

Sunday afternoon, February 10, will be devoted to the regular business meetings of the Advisory Board for Medical Specialties and the Federation of State Medical Boards of the United States.

Monday, February 11, will be devoted to a symposium on Medical Education Tomorrow during the morning session. The introductory paper will deal with the "lasting values in medical education" as opposed to the more transitory or temporary values. In projecting the discussion of Medical Education Tomorrow, papers will be presented on medical education as a cultural experience, the importance of and concern over natural and physical sciences remaining basic in the education of the physician, the need for structuring medical education to adequately reflect medical research in both knowledge and attitudes, and the "pros and cons" of interpretation and correlation. Efforts will be made to deal with the factors that are most important in creating the current unrest among medical educators in the search for new and better objectives, as well as techniques and methodologies.

The afternoon session on February 11 will focus attention on Postgraduate Medical Education. The keynote of this session will deal with the importance and challenges presented by this field. This will be followed by a presentation of the development of medical school-state medical society postgraduate programs (an analysis of the Kansas story). The role of a community hospital in continuing education will be highlighted by the Hunterdoon experiment and the potential significance of its general pattern to postgraduate medical education. The regional-hospital-medical school affiliation potentialities as exemplified by such programs as the Michigan Plan and the New York University Plan will also be presented. This program should also be of high interest to hospital administrators, state and local medical societies, and directors of postgraduate programs of medical education as well as to medical school administrators and faculty personnel.

The Federation of State Medical Boards of the United States will hold their Annual Federation Banquet on Monday evening, February 11. On Tuesday, February 12, the Federation will conduct its annual program around the general theme of "Re-evaluation of the Licensing Examination." This challenging area of concern should be of interest to those engaged in the various aspects of undergraduate and graduate medical education as well as to those concerned with licensure.

MEDICAL NEWS

CALIFORNIA

Society News.—The Los Angeles Physicians' Art Society has elected Dr. Douglas D. McKinnon, president; Dr. Alonzo B. Cass, president-elect; and Dr. Victor M. Marshall, secretary-treasurer. Dr. Samuel P. Danno, this year's winner, received the society's rotating "Oscar" from Dr. William M. Nethery, Glendale.

Physicist to Address Cardiac Conference.—The Cardiac Surgical Conference at Mount Zion Hospital, San Francisco, will be addressed by Norbert Wiener, Ph.D., who will speak at 10:15 a. m. Dec. 1 in Herbst Hall on "Use of the Ballistocardiogram as Evidence of Vascular Dynamics." Dr. Wiener is professor of physics at Massachusetts Institute of Technology in Cambridge.

Personal.—Dr. John R. Upton, assistant clinical professor of obstetrics and gynecology, University of California Medical School, Berkeley-San Francisco, has been appointed by Queen Elizabeth II as an associate officer in the Order of St. John for "his pioneer work in blood banking and his service to the British Commonwealth of Nations." This order of chivalry, which is over 900 years old, discarded its military status in 1888 and became a purely service organization.

CONNECTICUT

Course on Economics of Medical Practice.—The Connecticut State Medical Society, in cooperation with Yale University School of Medicine, New Haven, department of public health, is sponsoring a course on the economics and relationships of medical practice at the Brady Auditorium, 310 Cedar St., New Haven. At 8 p. m., Dec. 5, a special lecture, "Role of the Physician in Preventive Medicine," will be delivered by Dr. Dwight H. Murray, Napa, Calif., President, American Medical Association. On Dec. 13, the series on "Careers in Medicine" will be continued with a discussion on surgery by Drs. Edward J. Ottenheimer, Willimantic, and William H. Curley Jr., Bridgeport.

FLORIDA

Medical Society Honors First Graduating Class.—At a pregraduation dinner sponsored by the faculty of the first graduating class of the University of Miami School of Medicine, Coral Gables, the Dade County Medical Association presented an engraved plaque bearing the English translation of the oath of Hippocrates. A brass plate below the engraving is inscribed: "Presented to the University of Miami School of Medicine in honor of its first graduating class June 11, 1956 by the Dade County Medical Association. Hunter B. Rogers, President, Vincent P. Corso, Secretary." Dr. Rogers was invited by Homer F. Marsh, Ph.D., professor of bacteriology and dean of the medical school, to administer the oath to the new physicians.

ILLINOIS

Lecture in Winnetka.—Dr. Lauretta Bender, professor of clinical psychiatry, New York University College of Medicine, and principal research scientist in child psychiatry, New York State Department of Mental Hygiene, will present "Problems of Early Development" Dec. 5, 8 p. m., at the North Shore Health Resort, 225 Sheridan Rd., Winnetka. Physicians are invited.

Meeting on Physical Medicine.—The Chicago Society of Physical Medicine and Rehabilitation will hold its regular meeting Dec. 1, 2 p. m., at the Institute of Physical Medicine and Rehabilitation, 619 N. Glen Oak Ave., Peoria. The program, "The Physiatrist and the Patient's Physician," will be presented by the medical staff, Institute of Physical Medicine and Rehabilitation, and representative members of the medical staffs of St. Francis Hospital and the Methodist Hospital of Central Illinois. At 3 p. m. there will be a tour of the institute. A social hour, 5 p. m., will precede dinner.

Chicago

Lectures on History of Surgery.—The International College of Surgeons is sponsoring a series of lectures on the history of surgery at the Surgeons' Hall of Fame, 1524 Lake Shore Dr. All physicians will be welcome to attend. On Dec. 4, "The Middle Ages in Medicine and the School of Salerno" will be considered by Mr. Loren MacKenney, professor of history, University of North Carolina, Chapel Hill.

Society News.—The Institute of Medicine of Chicago will hold its 41st annual meeting Dec. 4 at the Furniture Club of America, 17th floor, 667 N. McClurg Ct. (telephone during the meeting: WHitehall 4-8552). The open meeting at 8 p. m. will be preceded by the annual reception, 6 p. m., and dinner, 7 p. m., for fellows of the institute, their wives, and other guests. The presidential address, "The Medical Outlook from Washington, D. C." will be delivered at 9 p. m. by Dr. Lowell T. Coggeshall.

Symposium on Parenteral Therapy with Fluids.—A symposium on parenteral therapy with fluids, co-sponsored by the Chicago Medical Society and Baxter Laboratories, Inc., will be held at the Sheraton Hotel, Dec. 5-6, in connection with the 25th anniversary of Baxter Laboratories and pioneering by Chicago physicians in the development of such therapy. All physicians are invited to attend. There is no registration fee. The program, which will open with a review of the development of parenteral therapy with fluids by Dr. Karl A. Meyer, president, Chicago Medical Society, will include the following presentations:

Physiology of Acid Base Balance, Harry F. Weisberg, Chicago.
Diagnosis of Fluid Electrolyte Imbalance, Harvey R. Bernard, St. Louis
Third Body Space—Translocation of Fluid, Parker Vanamee, New York City.
Special Pediatric Problems, Charles U. Lowe, Buffalo.
Therapy of Fluid Electrolyte Problems, Carl O. Rice, Minneapolis.
Use of Blood, Ralph M. Hartwell, New Orleans.
Use of Plasma Volume Expanders, Jacob J. Weinstein, Washington, D C
Treatment of Burns, Major Bruce G. MacMillan, M.C., Brooke Army Medical Center, Fort Sam Houston, Texas.
Carbohydrates, Rachmiel Levine, Chicago.
Vitamins, Tom D. Spies, Birmingham.
Protein, William E. Abbott, Cleveland.
Fat, Frederick J. Stare, Boston.

IOWA

Tumor Conference.—The Iowa division, American Cancer Society, and the University Hospitals, State University of Iowa College of Medicine, Iowa City, will present a tumor conference Dec. 7-8. A symposium on leukemias and lymphomas will be conducted at 11 a. m. Friday, by Drs. Willis M. Fowler, John R. Carter, and Higdon B. Elkins. "Viruses and Cancer" by Dr. Richard E. Shope, Rockefeller Hospital for Medical Research, New York City, will be presented at 4:10 p. m. Friday, and a lecture on bone cancer, with special reference to cartilaginous tumors, will be given at 11 a. m. Saturday, by Dr. Granville A. Bennett, professor of pathology, University of Illinois College of Medicine, Chicago. The program will also include the following presentations by Iowa City participants:

Gynecologic Cancer—Helpful Hints in Diagnosis, William C. Keettel.
What Therapy Can Do for Female Pelvic Cancer, John H. Randall.
Cancer of the Breast. A Quarter Century at University Hospitals, Robert C. Hickey.
Palliation of Advanced Breast Cancer, Robert T. Tidrick.
The Pediatrician Discovers a Mass—What Then? John D. MacQueen.
The Surgeon and the Child with Cancer, John A. Gius.
Urological Diagnostic Hints, Raymond G. Bunge.
Recent Changes in Therapy of Cancer of the Gastrointestinal Tract, Rubin Flocks.
The Place of Isotopes in Cancer Care: Present and Future Potentials, Titus Evans, Ph.D.
Lesions Produced by Aminonitriles, Ignacio V. Ponseti.
Dermatologist and Cutaneous Cancers, Ruben Nomland.
Special Problems in Cutaneous Cancer for the Surgeon, Sidney E. Ziffren
Shadow in the Lung—the Internist, Paul M. Seebohm.
Shadow in the Lung—the Surgeon, Johann L. Ehrenhaft.

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

Dr. Marc Hollender Goes to Syracuse.—Dr. Marc H. Hollender, associate professor of psychiatry, University of Illinois College of Medicine, and staff member of the Institute for Psychoanalysis, has been appointed professor and chairman of the department of psychiatry at State University of New York College of Medicine at Syracuse. Dr. Hollender succeeds Dr. Edward J. Stainbrook, who resigned last February to become professor and chairman of psychiatry at the University of Southern California, Los Angeles, and chief of psychiatric services at Los Angeles County Hospital. Dr. Hollender has been affiliated with Cook County Hospital and the University of Illinois Neuropsychiatric Institute. From 1942 to 1946 he served in the Air Force Medical Corps. In 1949 he received certification in psychiatry from the American Board of Psychiatry and Neurology.

MASSACHUSETTS

Dr. Hume Goes to Virginia.—Dr. David M. Hume, assistant professor of surgery and director of surgical research at the Harvard Medical School, Boston, has been appointed professor of surgery at the Medical College of Virginia, Richmond, to succeed the late Dr. Isaac A. Bigger. He assumed his duties as professor and head of the department of surgery on Aug. 16.

Dr. Lennox Honored.—Dr. William G. Lennox, associate professor emeritus in neurology at Harvard Medical School, Boston, has been chosen by the American Pharmaceutical Manufacturers' Association as the recipient of its scientific award for his research on the adaption of psychotherapeutic agents in the treatment of mental diseases. Dr. Lennox is a past-president of the International League Against Epilepsy and a founder of the American Epilepsy League. The presentation to Dr. Lennox will be made at the mid-year meeting of the association, Dec. 11 at the Waldorf-Astoria Hotel in New York City.

Dr. Solomon Becomes Emeritus Professor.—Dr. Harry C. Solomon, Boston, who helped to shape the early development of the teaching of psychiatry in the Harvard Medical School, has become emeritus professor of psychiatry, but will continue as medical director and superintendent of the Boston Psychopathic Hospital, the major center for the teaching of psychiatry in the medical school. He is currently president-elect of the American Psychiatric Association and president of the Association for Research in Nervous and Mental Disease. Dr. Solomon served as a first lieutenant with the Army Medical Corps in 1918-1919 and during World War II was chief neuropsychiatric examiner of the Boston Recruiting and Induction Station and a consultant to the Secretary of War. Among his many scientific publications are "Syphilis of the Innocent," "Studies in Lobotomy," "Neurosyphilis," "The Frontal Lobes and Schizophrenia," and "Manual of Neuropsychiatry," of which he was co-editor.

MICHIGAN

Symposium on Trauma.—The fifth annual Symposium on Trauma, sponsored by the Wayne State University Medical School, Detroit, and the Michigan Regional Committee on Trauma, will be held Dec. 5. Exhibits will be shown in the morning at the Farwell Building. A complimentary luncheon sponsored by the Upjohn Company will be given in the Medical School Cafeteria. The presentation of Dr. Henry C. Marble, Boston, the afternoon guest speaker, will be followed by two panel discussions in the auditorium of the Lafayette Clinic Registration fee is $2. Interns and residents will be admitted free.

NEW JERSEY

Doctors' Chorus Aids Chronically Ill.—The doctors' chorus of the Essex County Medical Society recently presented to the Essex County service for the chronically ill $1,300, the net proceeds of the 1956 benefit concert, bringing to $11,500 its contributions to this service. The chorus closed its 1955-1956 season with the third benefit concert for the Roseville Y.M.C.A.

Visiting Chiefs at Hospital.—The Atlantic City Hospital will have as visiting chiefs pro-tem Dr. Bernard Fisher, assistant professor of surgery, University of Pittsburgh School of Medicine, Dec. 3-7; Dr. William T. Fitts Jr., associate professor of surgery, University of Pennsylvania School of Medicine, Philadelphia, Dec. 10-14; Dr. S. Leon Israel, associate professor of obstetrics and gynecology, University of Pennsylvania Graduate School of Medicine, Philadelphia, Dec. 17-19; Dr. Charles W. Charny, associate in urology, Hahnemann Medical College and Hospital of Philadelphia, Dec. 20-21.

Tumor Seminar.—The sixth annual slide seminar on "Unusual Tumors," sponsored by the New Jersey Society of Clinical Pathologists and the New Jersey State Department of Health, bureau of pathology, will be held at 2 p. m., Dec. 8, in the Essex House, Clinton and Broad streets, Newark. The moderator will be Dr. Arthur P. Stout, Institute for Cancer Research, Columbia University College of Physicians and Surgeons. All physicians are welcome. A social hour and dinner, with Dr. Stout as guest, will be held at the Essex House after the seminar. Reservations for the dinner may be made through Dr. Murray W. Shulman, Irvington General Hospital, Irvington, chairman of the seminar.

Annual Martland Lecture.—The Essex County Pathological and Anatomical Society will present the 20th annual Harrison S. Martland Lecture, Dec. 5, at the Academy of Medicine, 91 Lincoln Pk., Newark. Dr. Sidney Farber, professor of pathology, Harvard Medical School, and director of the Cancer Research Foundation at the Children's Hospital Center, Boston, will discuss "Progress in the Treatment and Control of Cancer." The meeting, which will be held in conjunction with the Academy of Medicine of New Jersey and the Essex County Medical Society, will be preceded by dinner at the Essex House Hotel, Broad Street. Reservations, $5 per person, should be sent to Dr. Murray W. Shulman, 913 20th St., Newark 8. All members of the profession are invited.

NEW MEXICO

Society News.—The New Mexico Medical Society has appointed Dr. Aaron E. Margulis, Santa Fe, as its state scientific editor and member of the *Rocky Mountain Medical Journal* editorial board, to succeed Dr. Carl H. Gellenthien, Valmora, who retired from the editorship after almost 12 years of service.

NEW YORK

Lecture in Gerontology.—Dr. Edmund V. Cowdry, director of the division of cancer research, Washington University School of Medicine, St. Louis, will deliver the third annual Lecture in Gerontology at the Hospital Division, Brooklyn Hebrew Home & Hospital for the Aged, 813 Howard Ave., Brooklyn, Dec 6, 8:30 p. m.

Assembly on Anesthesiology.—The 10th Postgraduate Assembly of the New York State Society of [illegible]tel New Yorker, New York City, Dec. [illegible]; at 9:30 a. m. with simultaneous panels on "Blood Transfusions: Problems, Results, Medicolegal Responsibilities" and "Current Trends in the Study of Kidney Function." Out-of-state participants in the former panel include C. Joseph Stetler, LL.M., director, Law Department, American Medical Association, Chicago, and Dr. William G. Workman, Bethesda, Md.; in the latter, Drs. Frederic C. Bartter, Bethesda, Md., and Joseph E. Murray, Boston. After roundtable luncheons at 12:30 p. m., panels will be presented on "Light Anesthesia, Balanced Anesthesia, or Polypharmacy" and "Circulatory Stress." Out-of-state participants in the former will include Drs. C. Ronald Stephen, Durham, N. C., and Philip D. Woodbridge, Greenfield, Mass., and in the latter, Dr. Howard A. Frank, Boston. On Thursday afternoon, there will be a closed circuit telecast. The New York State Society of Anesthesiologists will be hosts at the annual cocktail party (7 p. m.) and dinner-dance (8 p. m.), honoring Dr. Emory A. Rovenstine, New York City. Friday morning Dr. Robert M. Smith, Boston, will serve as chairman on a panel, "Management of the Infant for Surgery," in which the participants will be Drs. C. Everett Koop, Philadelphia; William O. McQuiston, Peoria, Ill.; and Earle L. Wrenn Jr., Memphis, Tenn. Simultaneously, Dr. James E. Eckenhoff, Philadelphia, will be chairman of a panel on antidotes in anesthesiology, with the following collaborators: Dr. John Adriani, New Orleans,

Mathae, George Herman ⊕ St. Louis; St. Louis University School of Medicine, St. Louis, 1909; also a dentist and lawyer; on the staff of the Bethesda General Hospital and the Lutheran Hospital, where he died Sept. 22, aged 74, of cerebral arteriosclerosis.

McGee, James Patton ⊕ Oklahoma City; Emory University School of Medicine, Atlanta, Ga., 1916; professor of ophthalmology at the University of Oklahoma School of Medicine; died in St. Anthony Hospital Sept. 11, aged 65, of myocardial infarction.

McHugh, Francis Thomas ⊕ Chippewa Falls, Wis.; Bennett Medical College, Chicago, 1911; interned at the Cook County Hospital in Chicago; died Sept. 5, aged 75, of coronary thrombosis.

McLeod, Frederick Leon, Los Angeles; Lincoln Medical College of Cotner University, Lincoln, Neb., 1901; College of Physicians and Surgeons, Baltimore, 1907; an associate member of the American Medical Association; formerly practiced in Lincoln, Neb., where he was on the staff of St. Elizabeth Hospital; died Aug. 24, aged 77, of subarachnoid hemorrhage and congestive heart disease.

Meredith, Loren Kenneth ⊕ Des Moines, Iowa; University of Michigan Medical School, Ann Arbor, 1916; member of the American Academy of General Practice and the Association of Life Insurance Medical Directors of America; veteran of World War I; medical director for the National Life Company and the Iowa Life Insurance Company; died in the Rochester Methodist Hospital, Rochester, Minn., Sept. 13, aged 65, of an abdominal hemorrhage.

Miller, George William ⊕ Norristown, Pa.; Jefferson Medical College of Philadelphia, 1906; fellow of the American College of Surgeons; served as professor of general anatomy in the Temple University School of Dentistry, Philadelphia, as associate in anatomy at his alma mater, and on the staff of the department of applied anatomy at Temple University School of Medicine in Philadelphia; veteran of World War I; on the staffs of the Sacred Heart Hospital and the Montgomery Hospital, where he died Sept. 5, aged 74, of chronic lymphatic leukemia.

Moore, Leland Oliver Walter ⊕ Colonel, U. S. Army, retired, Washington, D. C.; Cooper Medical College, San Francisco, 1912; veteran of World War I; entered the Medical Corps of the U. S. Army in 1920 and retired Nov. 30, 1945; fellow of the American College of Surgeons; formerly professor of military science and tactics at George Washington University School of Medicine; died in the Walter Reed Army Hospital Aug. 28, aged 67, of cancer.

Murphy, Jewyl Booth, Redwood City, Calif.; University of Texas School of Medicine, Galveston, 1922; member of the American Academy of Pediatrics; interned at the Children's Hospital in San Francisco, where she was on the staff of the University of California Hospital; formerly on the staff of the Community Hospital of San Mateo County in San Mateo; died Aug. 30, aged 60, of carcinoma of the colon.

Nelson, Oscar Emil, Stewart, Minn.; Chicago College of Medicine and Surgery, Chicago, 1910, died Aug. 19, aged 79, of cancer.

Nicoll, Alexander, New York City; Columbia University College of Physicians and Surgeons, New York City, 1903, an associate member of the American Medical Association; fellow of the American College of Surgeons; veteran of World War I; at one time on the faculty of Fordham University School of Medicine; served on the staffs of the Central Suffolk Hospital in Riverhead, St. Elizabeth's, Fordham, Mother Cabrini Memorial and St. Francis' hospitals; died in the Southside Hospital, Bay Shore, Sept. 24, aged 75.

Nilson, Helmer Jonas ⊕ North Mankato, Minn.; University of Minnesota Medical School, Minneapolis, 1932; member of the American Academy of General Practice; served as health officer; on the staffs of St. Joseph's Hospital and the Immanuel Hospital, Mankato, where he died Aug. 31, aged 63, of a coronary attack.

North, William R. ⊕ Nokomis, Fla.; Beaumont Hospital Medical College, St. Louis, 1900; member of the Missouri State Medical Association; formerly practiced in St. Louis, where he was on the staff of the Evangelical Deaconess Hospital; died in Labadie, Mo., Aug. 29, aged 80, of cancer.

Ogden, Arthur White ⊕ Joliet, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1913; died Aug. 17, aged 72, of arteriosclerotic heart disease.

Ogden, Michael Alexander ⊕ Passaic, N. J.; University of Odessa Faculty of Medicine, Odessa, Russia, 1918; specialist certified by the American Board of Pathology; fellow of the American College of Physicians; served on the faculty of the Louisiana State University School of Medicine in New Orleans; for many years on the staff of the Passaic General Hospital, where he died Sept. 13, aged 63, of coronary disease.

Oliver, Adlai Stevenson ⊕ Raleigh, N. C.; Jefferson Medical College of Philadelphia, 1914; specialist certified by the American Board of Obstetrics and Gynecology; on the staffs of the Rex and St. Agnes hospitals; died Aug. 20, aged 64, of coronary artery disease.

Orr, James Edward, Seneca, S. C.; Medical College of South Carolina, Charleston, 1931; died Aug. 28, aged 53, of coronary thrombosis.

Outland, James Alfred, Murray, Ky.; University of Louisville School of Medicine, Louisville, 1912; member of the Kentucky State Medical Association; public health physician for Graves, Calloway, and Trigg counties; died Aug. 24, aged 71, of cancer.

Mackenzie, Simon Samuel ⊕ Akron, Ohio; University of Buffalo School of Medicine, Buffalo, 1897; for many years practiced in Warren, where he was on the staff of the Warren Memorial Hospital; died Aug. 24, aged 83, of heart disease.

Pace, Arthur Albert ⊕ Toledo, Iowa; Detroit College of Medicine, Detroit, 1896; veteran of World War I; served as mayor, councilman, and member of the school board; formerly associated with the Indian Service; on the staff of the Evangelical Hospital, Marshalltown; died Aug. 8, aged 86, of heart disease.

Palmer, Mary Simpson McCarty, Orchard Lake, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1886; died Sept. 11, aged 94, of heart disease.

Pedrick, William Weaver ⊕ Glassboro, N. J., Temple University School of Medicine, Philadelphia, 1922; member of the Industrial Medical Association; for many years president of the Gloucester County Health Association, and physician for the public schools; past-president of the board of health; died in the Elmer (N. J.) Community Hospital Aug. 10, aged 60, of coronary thrombosis.

Philo, Rae Morris, New Haven, N. Y.; Syracuse University College of Medicine, Syracuse, 1913; died July 28, aged 67, of angina pectoris.

Price, John Thomas, Harrodsburg, Ky.; Hospital College of Medicine, Louisville, 1895; an associate member of the American Medical Association; died in the James B. Haggin Memorial Hospital Aug. 14, aged 88.

Price, Lucius Grant, St. Petersburg, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1890; died Aug. 12, aged 89, of arteriosclerosis.

Quinn, Francis Peter ⊕ Dubuque, Iowa; State University of Iowa College of Medicine, Iowa City, 1921; member of the American Academy of Ophthalmology and Otolaryngology; served during World War II; died Aug. 8, aged 64, of bronchial asthma.

Rauchschwalbe, Lothar Ernst ⊕ Oconto Falls, Wis.; Loyola University School of Medicine, Chicago, 1930; on the staff of the Community Memorial Hospital, died Aug. 12, aged 53, of coronary occlusion.

Rebbeck, Elmer William, Pittsburgh; Hahnemann Medical College and Hospital of Philadelphia, 1925; an associate member of the American Medical Association, fellow of the American College of Surgeons; veteran of World War II; on the staff of the Shadyside Hospital, where he died Aug. 19, aged 54, of arteriosclerotic heart disease and pulmonary embolism.

Rice, Edward Martin ⊕ Wauwatosa, Wis., Milwaukee Medical College, Milwaukee, 1903, also a graduate in law; honorary member of the staff, St. Luke's Hospital in Milwaukee; died Aug. 26, aged 83, of uremia.

Roberts, Edward Russell ⊕ Bridgeport, Conn.; Medical School of Maine, Portland, 1913, specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otological Society; fellow of the American College of Surgeons; veteran of World War I; past-president of the Bridgeport Medical Society; on the staff of the Bridgeport Hospital; died Aug. 26, aged 67, of cerebral hemorrhage.

Robertson, William S., Danville, Va.; College of Physicians and Surgeons, Baltimore, 1885; died in Lynchburg Aug. 23, aged 95, of cerebral vascular accident and arteriosclerosis.

Rogers, Edmund Augustus ⊕ Brookline, Mass.; Baltimore Medical College, Baltimore, 1904; veteran of World War I; died in the New England Deaconess Hospital, Boston, Aug. 31, aged 74, of acute myocardial infarction.

Schwarzmann, Markus ⊕ New York City; Julius-Maximilians-Universität Medizinische Fakultät, Würzburg, Bavaria, Germany, 1922; died Sept. 6, aged 63, of cancer of the rectum.

Spearman, Clyde Herman, Coffeeville, Miss.; University of Nashville Medical Department, Nashville, Tenn., 1906; died Sept. 17, aged 72, in an automobile accident.

Spencer, Floyd Henry ⊕ St. Joseph, Mo.; Central Medical College of St. Joseph, 1900; veteran of World War I; past-president of the Buchanan County Medical Society; past-president of the city board of health; member and past-president of the staff, Missouri Methodist Hospital; member of the staff of St. Joseph's Hospital; past-president of the staff of State Hospital No. 2; died in the Veterans Administration Hospital, Wadsworth, Kan., Oct. 4, aged 77, of cardiac hypertrophy.

Stapp, Fred Brown ⊕ Chattanooga, Tenn.; Bellevue Hospital Medical College, New York City, 1884; past-president of the Hamilton County Medical Society; for many years medical examiner for Metropolitan Life Insurance Company; served as chief of staff at Baroness Erlanger Hospital; died Aug. 4, aged 95.

Stattman, Bernard ⊕ Brooklyn, N. Y.; University and Bellevue Hospital Medical College, New York City, 1908; on the staff of the Samaritan Hospital, where he died Aug. 27, aged 69, of coronary thrombosis.

Steele, Ernest Richmond, Dover, Del.; Jefferson Medical College of Philadelphia, 1901; died in the Kent General Hospital June 29, aged 80, of myocardial infarction.

Stewart, Thomas Weir ⊕ Lithonia, Ga., University of Louisville Medical Department, Louisville, Ky., 1915; died Aug. 13, aged 69, of pulmonary edema and coronary occlusion.

Swanson, Albert John, Costa Mesa, Calif., Chicago College of Medicine and Surgery, Chicago, 1908, an associate member of the American Medical Association, died July 10, aged 74, of cancer.

Swetlow, George Irving ⊕ Brooklyn, N. Y.; Long Island College Hospital, Brooklyn, N. Y., 1920; also a lawyer; served on the faculty of the Brooklyn Law School; fellow of the American College of Physicians; consulting neuropsychiatrist at Cumberland Hospital; died in the Brooklyn Hospital Aug. 20, aged 58, of pulmonary edema, coronary heart disease, and diabetes mellitus.

Taylor, Willis Harvey, Omaha; University of Nebraska College of Medicine, Omaha, 1911; professor emeritus of clinical obstetrics and gynecology at his alma mater; an associate member of the American Medical Association; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons, in 1941 elected president of the Nebraska Methodist Hospital; on the staff of the Immanuel Hospital; died Aug. 5, aged 69, of coronary thrombosis.

Thomson, Joseph Oscar, Stillwater, Okla.; McGill University Faculty of Medicine, Montreal, Canada, 1909; for many years a missionary in China; fellow of the American College of Surgeons; formerly physician at the Oberlin College in Oberlin, Ohio; served as medical director for the General Motors Tank Plant in Flint, Mich.; retired in 1951 from the faculty of the Oklahoma Agricultural and Mechanical College; died in the Stillwater Municipal Hospital Oct. 2, aged 71, of cerebral hemorrhage.

Tompkins, Rutledge Chaney, Minden, La.; University of Nashville Medical Department, Nashville, Tenn., 1901; for many years coroner of Webster Parish, and associated with the Webster Parish Health Unit in Minden and Springhill; at one time medical superintendent of the State Colony and Training School in Alexandria; died July 21, aged 79, of coronary thrombosis.

Totman, Harold Maydole ⊕ Syracuse, N. Y.; Syracuse University College of Medicine, Syracuse, 1924; veteran of World War I; served on the staff of St. Joseph's Hospital; medical director of the Unity Life and Accident Insurance Company; died in St. Joseph's Hospital Aug. 5, aged 59, of lung cancer.

Townsend, Jesse P., Berryman, Mo., Beaumont Hospital Medical College, St. Louis, 1897; died in the Farmington (Mo.) State Hospital Sept. 2, aged 83.

Trippel, Edward ⊕ O'Fallon, Ill., St. Louis University School of Medicine, St. Louis, 1912; died in St. Elizabeth's Hospital, Belleville, Aug. 22, aged 67, of diabetes mellitus.

Voorhees, Bert Grant, Elmira, N. Y., Jefferson Medical College of Philadelphia, 1914; an associate member of the American Medical Association; served in France during World War I; on the staffs of Arnot-Ogden Memorial and St. Joseph's hospitals; died Sept. 29, aged 70, of cerebral hemorrhage

Waddell, William Everett, Los Angeles; Pulte Medical College, Homeopathic, Cincinnati, 1887; specialist certified by the American Board of Otolaryngology; an associate member of the American Medical Association; fellow of the American College of Surgeons; served on the staff of St. Vincent's Hospital, where he died Aug. 24, aged 91, of pulmonary thrombosis.

Walch, John Joseph ⊕ Escanaba, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1912; past-president of the Upper Peninsula Medical Society; served as a member of the state board of registration in medicine. past-president of the Delta County Medical Society; formerly a member of the board of education; a member of the board of directors of the State Bank of Escanaba; on the staff of St. Francis Hospital, where he died Sept. 5, aged 69, of cerebral thrombosis.

Weisbrod, Samuel Lyon, Milford, Mich.; Trinity Medical College, Toronto, Ontario, Canada, 1894; died Aug. 21, aged 87, of coronary thrombosis.

Wheelock, Harry Elmer ⊕ Fredonia, N. Y.; Jefferson Medical College of Philadelphia, 1914; fellow of the American College of Surgeons; veteran of World War I; for many years a member and president of the school board; a member of the board of visitors of Fredonia State Teachers College, and of the Roswell Park Memorial Institute in Buffalo; on the staff of the Brooks Memorial Hospital in Dunkirk, where he died Aug. 25, aged 65, of coronary thrombosis.

Whitehead, John Maloy ⊕ Indianapolis; Indiana University School of Medicine, Indianapolis, 1918; veteran of World War I; retired chief anesthetist for Methodist Hospital, where he died Aug. 9, aged 67, of cerebral infarction.

Wiese, Milton Arthur ⊕ Libertyville, Ill.; University of Illinois College of Medicine, Chicago, 1914; on the staffs of St. Therese Hospital in Waukegan and the Condell Memorial Hospital in Libertyville, where he died Sept. 18, aged 64, of coronary occlusion.

Willey, Arthur J., Marion, Ohio; Ohio Medical University, Columbus, 1898; fellow of the American College of Surgeons; also a dentist; on the staff of the Marion General Hospital; died Sept. 1, aged 84, of cerebral hemorrhage.

Williams, Frederick Russell ⊕ Worcester, Mass.; Long Island College Hospital, Brooklyn, N. Y., 1905; died in the Memorial Hospital Aug. 10, aged 73.

Williamson, Walter Scott ⊕ Captain, U. S. Army, San Antonio, Texas; University of Oklahoma School of Medicine, Oklahoma City, 1950; interned at the Mercy Hospital and at the University Hospitals in Oklahoma City, Okla.; resident at the Brooke Army Hospital; died in Fort Sam Houston July 8, aged 34, of coronary thrombosis.

Winters, William Winfred, Boliver, Tenn.; University of Nashville Medical Department, 1904; veteran of World War I; formerly on the staff of the Western State Hospital in Western State Hospital; at one time on the staff of the Veterans Administration Hospital in Minneapolis; served as resident physician at the Davidson County Hospital in Nashville; died Aug. 14, aged 80, of bronchopneumonia and adenocarcinoma of the prostate.

Williams, Philip Banatyne, Rome, Pa.; Jefferson Medical College of Philadelphia, 1895; died in the Robert Packer Hospital, Sayre, Aug. 11, aged 82, of arteriosclerotic heart disease.

FOREIGN LETTERS

AUSTRIA

Tuberculous Appendicitis.—At the meeting of the Society for Pediatrics in Vienna on May 9, Dr. H. H. Orel presented the case of a 14-year-old boy who had received orthopedic treatment since his 4th year because of the sequels of tuberculous coxitis. In February, 1956, a tuberculous inflammation of the knee joint had developed after a fall. In the middle of March, the patient had an acute attack of appendicitis and his appendix was removed. Several days after the operation, symptoms of a tuberculous meningitis appeared, and clinical and bacteriological studies corroborated this diagnosis. The meningitis subsided after treatment with streptomycin. Histological examination of the removed appendix revealed tuberculosis of the appendix. The concurrence of the tuberculous appendicitis, meningitis, and arthritis is regarded as the result of a hematogenous dissemination of the tuberculosis resulting from the fall. Dr. Orel stated that the appendicitis was an isolated process.

Personality of Obese Children.—At the same meeting Dr. H. E. Huber reported personality studies of 50 obese children and 50 children of normal weight. The obese children came from families that were not unusual except that there seemed to be a familial tendency to obesity; most of the children ate more than the average child, and their play and games usually involved little exercise. Intelligence tests revealed that the obese children had normal intelligence, memory, perseverance, dexterity, and fantasy and average school performances, but they were relatively inactive, slow or lazy, and defective in social contacts. This last factor was not primary but was the result of the reactions of others to their physical abnormality and their inactivity.

SWITZERLAND

Aldosterone Hypersecretion in Pituitary Basophilism and Adrenal Cortical Hyperfunction.—For many years it was supposed that a hypersecretion of mineralocorticoids might play a role in the pathogenesis of those cases of pituitary basophilism and adrenal cortical hyperfunction that were associated with edema, polyuria, hypernatremia, alkalosis, and hypokalemia, but no conclusion could be reached until a method of assaying the urinary excretion of aldosterone became available. J. P. Doret (*Semaine hôp. Paris* 32:2921, 1956) found the mineralocorticoid level to be either normal or increased in patients with this condition but could not explain these contradictory findings. In the three patients with this condition reported, the presence of a marked retention of water and sodium and of alkalosis with hypokalemia suggested hyperaldosteronism. In the first case, which occurred subsequent to a large chromophobe tumor, no hormone evaluation was available; in the second (reported by Brown and co-workers), there was an increase in excretion of aldosterone; and in the third (the author's second case), due to the presence of a mixed adenocarcinoma of the pituitary gland, hyperaldosteronuria could be demonstrated.

Streptococcus Typing.—A. Rivkine (*Schweiz. med. Wchnschr.* 86:1098, 1956) reports an attempt to type the hemolytic streptococci in children of a more or less homogeneous environment (from orphanages and boarding schools). He found that, since virulence is a potential and labile characteristic, independent of the strain of the pathogen, it is not possible to predict whether a carrier will be dangerous. No laboratory test reveals the virulence for man of a given strain. A strain from a sick carrier is more likely to be virulent than one from a healthy carrier. The occurrence of a disease in the carrier of a virulent strain depends on the susceptibility or resistance of the carrier. The communicability of a strain does not seem to be correlated with its virulence. If patients are to be isolated, those with the same type should be grouped together. Even when this precaution is taken, there is the risk of reimplantation of the common strain at an increased level of virulence.

UNITED KINGDOM

Hepatic Coma.—Dr. Sheila Sherlock and co-workers (*Lancet* 2:689, 1956) showed that clinical findings similar to those in spontaneously developing hepatic coma can be induced in patients with liver disease by the oral administration either of a high-protein diet or of nitrogenous compounds, such as urea or methionine. They believe that, by passing through a diseased liver, nitrogenous materials in the intestine reach the systemic circulation and thus the brain. This theory suggested the treatment of impending hepatic coma by withdrawal of protein and nitrogen-containing substances. The authors reported a series of 66 patients with liver disease complicated by hepatic coma or precoma whom they treated in this way. As the bacterial flora of the small intestine are increased in hepatic cirrhosis, chlortetracycline was administered to reduce their number and their effect on methionine. The patients suffered from such conditions as acute viral hepatitis, hepatic cirrhosis, obstructive jaundice, and ischemic necrosis of the liver. Three lines of treatment were used: 1. The intestines were emptied and kept free of all nitrogen-containing substances. 2. All dietary protein was stopped. 3. About 1,600 calories were supplied daily as glucose drinks or as 20% glucose given through an intragastric drip or, if necessary, as dextrose given intravenously. During the recovery period, protein was added in 20-gm. increments on alternate days. Any relapse was treated by withdrawing all protein. The lower intestine was emptied by an enema, and an oral dose of magnesium sulfate was given each day. The dose of chlortetracycline was 2 gm. initially, followed by 0.5 gm. every six hours for the duration of the symptoms or to a maximum of one week. As patients in impending hepatic coma are sensitive to sedatives, these were avoided whenever possible. Drugs known to induce hepatic coma, such as ammonium salts, acetazolamide, and morphine, were not used. A common precipitant of hepatic coma is gastroesophageal hemorrhage, which increases the nitrogen content of the intestine. This was treated with a Sengstaken esophageal compression balloon. Of the 66 patients, 39 recovered; of these, 21 had been in deep coma. Sodium glutamate was given intravenously to some patients but without effect. In view of the extremely poor prognosis of hepatic coma treated by other methods, the authors believe that the protein-withdrawal treatment represents an advance. Some patients received low-protein diets for two years and maintained body weight and positive nitrogen balance.

Effect of Giving Live Influenza Virus.—Immunization against epidemic influenza is normally done by subcutaneous inoculation of virus inactivated by formaldehyde. Chick embryos are used for growing the virus. However, as there would not be enough fertile eggs available to supply sufficient inactivated virus in the event of a severe influenza epidemic, Isaacs and Roden, of the medical research council and the common cold research unit have tried inoculating volunteers with live influenza-A virus prepared by one amniotic passage and either 1, 4, or 10 allantoic passages in chick embryos. The inoculum contained between 10^4 and 10^6 egg-infective doses. The initial inoculation was done intranasally, but subsequently it was done by pharyngeal spray. Seventeen volunteers participated in four separate trials. No symptoms of respiratory infection developed; no virus was recovered from the volunteers; and no increase in serum antibody to the influenza antigen was observed. It was therefore concluded that the virus lost its ability to multiply in man and that this method would be unsuitable for mass immunization.

The items in these letters are contributed by regular correspondents in the various foreign countries.

Health in Ceylon.—A health survey published by the Ministry of Health of Ceylon reveals the advances that have been made in medical treatment and public health in only a decade (D. M. Silva, Health Progress in Ceylon, [illegible]). In seven years the general death rate has [illegible] it is 10.9 per 1,000, which is lower than that of Great Britain. Similarly, the infant mortality rate has been halved in the same period; it is now 71 per 1,000 live births. Maternal mortality has fallen to less than a third of the figure of seven years ago. These changes are not surprising in view of the large increase in expenditure for health services in Ceylon since dominion status was conferred on it in 1948. The expenditure per capita for health in 1945 was only three rupees; in 1953, it was 11 rupees. Health services have expanded, being partly aided by the World Health Organization and the Colombo Plan. One of the biggest contributions to public health has been the control of malaria, which until recently was responsible for more morbidity than any other disease. In 1946, there were 2,750,000 cases in Ceylon, or 412 per 1,000 population, with a death rate of 1.8 per 1,000. After 1947, all infected persons were treated and every habitation sprayed with chlorophenothane (DDT). In eight years the morbidity rate has been reduced from 412 to less than 5 per 1,000.

Tuberculosis is a severe endemic disease in Ceylon. Over 2 million of the population of 8 million have had a tuberculin skin test, and nearly a million negative reactors were given BCG vaccination. Mass miniature radiography, which was started in 1950, showed that 1% of all those examined had active tuberculosis. The death rate from this disease has been halved in the last three years, but ancylostomiasis still presents a problem and is responsible for more ill health than tuberculosis. A decade ago a third of the rural population was undernourished, not because of a shortage of food but because poverty prevented them from buying it. The lot is improving, but 16% of all school children still show signs of malnutrition. Cows are also undernourished, and this affects the quality and quantity of milk. The average yield per cow is only 60 gal., which is about a 10th that of a normal pasture-fed cow in Great Britain. The per capita consumption of milk in Ceylon is therefore only 2 oz. daily. The government issues free imported dried milk to about 250,000 people daily.

The improved health and nutrition services have resulted in a large increase in the population. The excess of births over deaths is now 28.5 per 1,000, compared with 4.5 in Great Britain; it is the highest figure in the world. This in itself presents a problem, because money must be found for more food, more schools, and more houses to keep pace with the rising population. This may make it difficult to find funds to maintain high standards of medical care, nutrition, and education. Large areas in the northeast of the island are being developed and made free from malaria; jungle areas are being cleared; and irrigation is being introduced. This may enable the island to support the increasing population.

Death of Obstetrician to the Royal Family.—Sir William Gilliatt, who was obstetrician to the Royal Family, died on Sept. 27 as a result of a traffic accident. He had been president of the Royal College of Obstetricians and Gynecologists and of the Royal Society of Medicine.

Cytological Diagnosis of Sex.—The claim of James (*Lancet* 1:202, 1956) that the sex of a fetus can be diagnosed from the examination of karyosomes in amniotic fluid cells has been confirmed by Sachs and co-workers (*Lancet* 2:795, 1956). They obtained amniotic fluid by puncture of the membranes and in the earlier months of pregnancy, with the exception of the third month, by abdominal puncture. The fluid was centrifuged, and the deposit stained on a slide with the Feulgen method, which is specific for desoxyribosenucleic acid. This is only present in the chromosomes and gives a clear staining of the karyosomes. The karyosome is longer in the cells of a female than of a male, and the percentage of cells with a karyosome at the nuclear membrane is greater. The figures are 4% in male cells and 38% in female cells. Dixon and Torr examined chromosomal sex differences in cells contained in oral smears (*Brit. M. J.* 2:799, 1956). Oral smears from 257 persons, representing a wide range of age and racial variation, were examined by Feulgen staining. In 162 male smears, no sex chromatin was seen, whereas, by contrast, in most of the 95 female smears between 30% and 50% of the cells counted contained a sex-chromatin mass. In the female smears, the sex chromatin was usually first seen in one of the first five cells counted. As this occurred with such regularity it was decided that a count of 25 cells from an oral mucosal smear was adequate for sex determination.

Histoplasmosis.—Prof. W. Symmers has described the first proved case of histoplasmosis in which infection was acquired in Great Britain (*Brit. M. J.* 2:786, 1956). Histoplasma capsulatum was isolated from a biopsy specimen taken from a patient who, like the other members of his household, had never been out of the British Isles. About a dozen cases have been reported in Great Britain, but, in each case, the patients had lived abroad in an area where histoplasmosis was endemic. In Symmers' patient, the only manifestations of the infection were enlargement of the cervical lymph nodes and a positive skin reaction to histoplasmin. H. capsulatum was found in cultures from one of the lymph nodes. No members of the patient's household reacted to intradermal histoplasmin, and the patient's hobbies and recreation did not expose him to any environment that has been incriminated as a source of infection.

Enzyme Tests for Detection of Glycosuria.—Hunt and co-workers reported on the use of glucose oxidase for the routine detection of glycosuria in diabetics (*Brit. M. J.* 2:586, 1956). The purified enzyme is now available commercially in testing preparations known as Tes-Tape and Clinistix. The former is a roll of test paper impregnated with glucose oxidase, *o*-toluidine, a vegetable peroxidase, and a yellow dye. When the strip is dipped into a liquid containing glucose, the oxidase in the presence of air converts it to gluconic acid and hydrogen peroxide, which with the peroxidase converts the *o*-toluidine into a blue oxidation product. This with the yellow dye gives a color, ranging from light green through dark green to dark blue, according to the amount of glucose present. A color scale is provided with Tes-Tape to indicate colors corresponding to 0, 0.1, 0.25, 0.5, and 2 gm. of glucose per 100 ml. of urine. Clinistix is a preparation in the form of separate strips of thick paper resembling book matches. No color scale is provided, as the test is purely qualitative. From tests on urine specimens from 174 diabetics known to be excreting glucose, from 43 patients excreting no glucose or only trace amounts, and from 46 normal subjects, it was concluded that both Tes-Tape and Clinistix are sufficiently accurate for the qualitative detection of glucose in urine. The limit of sensitivity is about 0.1 gm. per 100 ml. The advantage of these preparations is that no apparatus, boiling, or white tiles are necessary and that the test is specific for glucose; however, strict chemical cleanliness is necessary. Occasional false-positive tests were observed, but in no case did glycosuria go undetected. The authors are not satisfied that the preparations permit an accurate estimation of the amount of glucose present in urine. There was a significant difference in the amounts reported by different observers on the same urine specimens, and even greater discrepancies occurred when untrained observers read the results.

New Health Service Regulations.—The Minister of Health, after consultation with the representatives of the medical profession, has incorporated certain new regulations in the National Health Service code. These became effective on Oct. 1. The main amendments provide for (1) periodic reviews by executive councils of consents given to a physician to employ a permanent assistant; (2) a new procedure for identifying patients on a physician's list who are at a school or residential institution and, when they have gone away, for removing them from the list; (3) the abolition of back debits and back credits; (4) making a deputy to a physician responsible for his actions when both the deputy and the physician for whom he is deputizing are on the same medical lists; (5) enabling executive councils to make arrangements for the treatment of a physician's patients when he is absent or disabled; and (6) increasing the fee payable to a physician for the treatment of temporary residents at certain types of institution.

Overpopulation.—Overpopulation of the world, famine, disease, and disaster are not inevitable according to Dr. C. B. Goodhart, who addressed the annual meeting of the British Association for the Advancement of Science. Man's fertility may be lowered by natural selection. Families of lower fertility but otherwise good qualities are more likely to survive. In the British peerage, wealth in women is associated with infertility. An heiress by definition comes of a family of low fertility, for otherwise there would be siblings or other relatives to share her wealth. Many noble families have become extinct by the marriages of the sons to heiresses whose riches were as great as their infertility. The unattractive wife of King Louis XV of France had 10 children, whereas the attractive Mme. de Pompadour, his mistress, despite all her wishes, had only one child, who died young. Many other human characteristics leading to success in life are associated with low fertility; this, in turn, usually results in a higher standard of living. Population increase is primarily a biological phenomenon. The arguments of Malthus were based on the assumption that man had a specific and constant rate of reproduction, which would be the same in the future unless artificially altered. This assumption is not necessarily true. The present rate of increase in the population is quite exceptional. For 99% of his history, man lived as a nomadic hunter and food collector. The densely settled agricultural and urban communities characteristic of the last few millenniums are a relatively recent development. We cannot assume that the high fecundity found in these dense and unhealthy aggregations of population is necessarily typical of the human species. Declining numbers are found not only in primitive peoples brought into contact with civilization but also in many of the most advanced nations. The conditions produced by civilization and a high standard of living may in themselves be unfavorable to fertility. Those qualities leading to success in man may have become genetically correlated with relatively low fecundity.

Fertility in Scotland.—The *British Medical Journal* of Sept. 8 contains an annotation stating that, as a result of the steady fall in the birth rate from 316 per 1,000 married women in the period 1860 to 1862 to 132 in the period 1950 to 1952, the average size of families in Scotland has fallen from 6 to 2.5 children. The decline in childhood mortality has compensated for only part of the decline in fertility. The infant mortality rate is now 25% of the rate of 50 years ago, and the death rate for children under 10 years of age is about 12% of the rate of 50 years ago. A recent publication of the General Register Office, Edinburgh, presents statistics showing that almost 20% of all the married women in a random sample have no children and that only 0.6% have 10 or more children. The number of women at 23 years of age with no children and the number with one child are about equal. By the time a woman is 24 years of age, the average size of her family exceeds one child, but not until she is 32 years old does the average exceed two children.

For marriages under two years' duration, the number of childless women exceeds the number of women with one or more children. One-child families are the most frequent for women who have been married two to five years, but after six years of marriage the two-child families predominate. For marriages of the same duration, the average size of the family decreases with the increasing age of the mother at marriage. When analyzed by social class of the husband, the size of the family rises from an average of 1.48 for social class 1 to 2.58 for social class 5. There is a wide range in the average size of the family classified according to the occupation of the mother: for example, 70% of married clerks, typists, and office workers have no children, while only 12% of charwomen and office cleaners are childless. However, over half the women in the former group had been married for less than five years, while over half of those in the latter group had been married for 15 or more years. Geographical differences in the average size of the family are small: the rural areas have the largest families (average size about 2.11) and the small towns the smallest (1.90).

Streptococci on the Umbilicus.—The *British Medical Journal* of Sept. 8 contains an article by Drs. Boissard and Eton and another by Drs. Kwantes and James who simultaneously conclude that many hitherto unexplained outbreaks of streptococcic infections in maternity hospitals can be traced to an umbilical source, and they make the plea that bacteriological investigation of the nursery should be carried out whenever a case of streptococcic infection is found in a mother or a member of the staff. There was no local sign of any infection in most of the infants whose cords were found to be infected. It is not surprising that the stump of the cord, consisting of dead tissue undergoing dissolution, should support the free growth of bacteria. What is surprising is that an infant with no acquired immunity and with only a few days' experience with bacteria of any kind should be able to keep virulent streptococci in check at the junction of dead and living tissue. These observations nevertheless show that the umbilicus can be a symptomless reservoir of such infection. Contaminated in the first instance probably by a nurse, it can evidently be the source from which the mother acquires a uterine infection and from which other babies in the ward acquire an umbilical infection. One effect of these findings must be that umbilical swabs be regularly included in those taken to determine the source of infection in puerperal fever.

No More Overtime in Mental Hospitals.—More than 26,000 male and female nurses in mental hospitals refused to work overtime after Oct. 1. The ban must worsen conditions already bad because of overcrowding and a shortage of staff workers. A last-minute effort to avert this will be made. The decision to ban overtime was taken by a vote of 399 to 381 and will continue until the demands of the Confederation of Health Service Employees are met in full. These include higher ordinary and overtime pay; a 44-hour week; and six weeks' annual leave, including bank holidays and weekly leaves. A 96-hour fortnight is the rule in both mental and general hospitals. The Industrial Court has rejected the confederation's request that overtime after 96 hours should be paid for at time and a quarter for the first two hours and time and a half thereafter. At present, overtime is paid for at the ordinary rate. Much overtime is worked and is popular with many employees as an additional source of income. Nurses commonly work 60 to 70 hours a week; many have broken down under the strain. Others have forsaken mental health work for other forms of nursing. Dissatisfaction is general throughout the service. The secretary of the confederation emphasized that no patient would be left uncared for because of the ban. Nurses will not be required to leave patients needing attention until a relief has arrived. While patients will not lose nursing care, they will be deprived of such things as entertainment, because no one will be available to supervise.

Eyeglasses Without Examination.—The harmful effects of eyeglasses bought in shops without an ophthalmologic examination or professional advice are being investigated. Results of the inquiry will be reported to the Minister of Health. Shop sales of glasses dwindled almost to nothing after the introduction of the National Health Service, which made it possible to obtain glasses free. However, since May, 1951, people have had to pay $2.80 and the cost of the frames. Again there is much indiscriminate buying. Glasses can be bought for as little as 28 cents a pair. Among those who buy their glasses from shops and peddlers are many old-age pensioners. Concern about increasing shop sales of eyeglasses was expressed in a resolution submitted at the Labor party conference in October that urged that plans be prepared for the next Labor government to stop this practice and reintroduce free glasses. The Guillebaud Committee on the cost of the National Health Service, in its report last January, recommended that, when it could be afforded, a substantial reduction in the charge for glasses should be given high priority.

THE LEISURE CORNER

SKIING AS WEEK-END RECREATION

"Travels in the mountains undertaken in the company of friends are the highest of all pleasures and the most charming of all delights of the senses are obtained. . . ." So wrote Conrad Gessner, physician of Zurich, Switzerland, in 1555. The peripatetic doctor did not mention skis as the model mode of "travels in the mountains," but it can be safely assumed he might have had them in mind, since men have used skis to journey in mountains for more than 4,500 years.

At any rate, millions of Americans, 400 years later, are taking the Swiss doctor's remarks to heart. Every week end, from November through April, depending on the weather, of course, the highways are filled with automobiles carrying skiers, young and old, to the snow-covered slopes; railroad stations resound to the joyful and enraptured shouts of athletes, aged 20 to 60, carrying skis and rucksacks like so many gay, brilliant banners.

These are the week-end athletes—office boy and office manager, factory hand and plant foreman, salesman and store executive—released by the shorter work week from the shackles of their jobs for long week ends. Two days a week they can be found shackled to two slim wooden boards, racing up and down snow-covered slopes to steep inclines with the abandon that is the distinguishing characteristic of their sport. Dangerous? A little, perhaps, but not so bad as a treacherous undertow or a fall from a horse, is the skier's retort. Difficult? Anything that can be learned on week ends, not necessarily consecutive, is not hard. Rugged? Persons in their 50's have been known to take up the sport for the first time and stay with it in their 60's.

Week-end athletes, of course, suffer one drawback—the uncertainties of the weather. In the summer they repeat the intonation of their childhood: "Rain, rain go away, come back another day." In the colder weather they look longingly to the skies for the gray clouds that spell the advent of snow. Physicians who can get away for several weeks at a time have a much better chance of ascertaining the truth of their ancient colleague's observation. Once they get the taste, the chances are they will become week-end athletes too. And since there are no age limits, skiing can become a family affair. Wife and children can easily fit in "the company of friends" to guarantee "the highest of all pleasures."

Mountains need not be high or overly rugged; sites are available for individual tastes and peace of mind. The only requisite is the desire. And as for the last, there is only one note of caution: once you get the desire, you never lose it. Nor need skiing be an expensive sport. It is only if you want it to be. However, it is not wise to stint on good equipment; poor equipment can be false economy.

Most important ingredients of your outfit are boots and bindings, since they are the links between skier and ski. Put on thick woolen socks before trying on the boots to make sure the boot will fit properly. Some ski experts even insist that you bring along your own socks for the fitting to make certain the boots will not feel too snug. As for the bindings, all-metal ones are considered the best, although some experts recommend a good grade of leather straps for beginners.

Skis, almost everyone agrees, should be of hickory wood. Other woods are unsatisfactory for various reasons, and metals and plastics have not been sufficiently tested to have won wide acceptance. Some experts say a ski must reach to the base of your thumb when you stand them erect; others insist weight must be considered. The latter advise a ski somewhat shorter than the base-of-thumb length. Good ski poles should reach from boot to armpit and be made of metal tubing or tonkin cane. Well-padded hand grips and good leather wrist straps are important.

Ski clothing generally is a matter of individual taste, but here the experts also have a word of caution. Designers for one of the foremost makers of ski clothing in the country advise that pants and jackets should be well fitted and tapered, yet full cut to permit freedom of movement. They say loose-fitting pants, for instance, tend to cause wind resistance. The material should be closely woven, smooth, and snow-repellent. Do not make the mistake of buying ski clothing for warmth, the experts add. Undergarments will supply warmth, but you must make sure they do not supply too much bulk as well. Then there are such incidentals as goggles, wax, mittens, sunburn preventives, and other items that individual skiers may like. Most of them are necessary, but none are too expensive.

Different conditions prevail in different parts of the country, which means that skiing techniques may vary from place to place. But no one has to become an expert in any or all types of skiing to enjoy the sport. No matter what time of life you begin, you have the rest of your active span of life to improve both style and technique—if you care, or if you have any style or technique to improve.

Of course, there are certain fundamental skills to learn. One school promises to teach skiing in a week. Whether you are interested in the Swiss school, or the Arlberg, or the Norwegian, or the American, it does not matter. Fundamentally there is one system of skiing. All schools are based on the snowplow or the snowplow turn. In the snowplow your skis form a reverse V to brake your momentum; in the snowplow turn, you turn right by shifting weight to the left ski, and left by shifting to the right ski. And above all, no matter what the school, the system, or the technique, you must learn to relax.

Since relaxation and leisure are inseparable, like ski and boot, what better way of combining both than by skimming through the dustless air of higher altitude, over the bluish luster of virgin snow, through wooded trails, enjoying the long, slow rhythm of great sweeping turns or knowing the enormous spray of powder snow thrown up by a jerked Christiania. And through it all courses the ecstasy and the strange intoxication of swift passage through the keen, sharp, clean, tangy atmosphere. Slalom!

MEDICAL FILM REVIEWS

Fractional Lumbar Epidural Analgesia: 16 mm, color, sound, showing time 12 minutes. Prepared by LeRoy W. Krumperman, M.D., Philadelphia. Produced in 1956 by Audio Productions, New York, for Sharp and Dohme Division of Merck and Company. *Procurable on loan from* LeRoy W. Krumperman, M.D., 3401 N. Broad St., Philadelphia 40.

The purpose of this film is to show a practical technique of performing lumbar epidural analgesia. The contents of the epidural tray are shown and described, and the value of this technique of regional analgesia for surgery as well as or a diagnostic and therapeutic block is pointed out. The technique of identifying the epidural space by using the "drop-sign" of Gutiurez is shown; also shown is the introduction of a polyvinyl catheter through the needle into the epidural space. By anatomic drawings, the film shows the proper position of the needle in the epidural space and also the polyvinyl catheter in the epidural space. The indications and contraindications for this form of regional analgesia are described, and there is also a comparison made between epidural and spinal analgesia, with the advantages and disadvantages of each technique pointed out. The over-all film is good; however, the advantages and disadvantages of other drugs and the other techniques for locating the epidural space should have been mentioned. The hazards of and the preparation for a reaction to a local anesthetic should have been discussed. The photography is good, and the film is recommended for surgeons, anesthesiologists, and members of hospital house staffs.

Dynamics of the Tubercle: In Vivo Observation of Pathogenesis and Effects of Chemotherapy in the Clark Rabbit Ear Chamber: 16 mm, color, sound, showing time 28 minutes. Prepared by Robert H. Ebert, M.D., and William R. Barclay, M.D., University of Chicago. Produced in 1956 by Churchill Wexler *Productions*, Los Angeles, *for and procurable on loan from* Pfizer Laboratories, Chas. Pfizer and Co., Inc., Brooklyn 6, N. Y.

This excellent film shows the effect of the introduction of disease in normal tissue and the results of chemotherapy upon the disease. The early part of the film explains normal circulation in the rabbit ear and describes in detail progressive changes in the normal vessels, blood cells, and connective tissue after the introduction of the tuberculosis organisms in a primary infec tion and also the development of the tubercle in reinfectio tuberculosis. The latter part of the film shows the effects o chemotherapy on the tubercle. This is an excellent teaching fil for histology, physiology, and pathology, since it demonstrat (1) normal tissue, (2) the result of introduction of infection i normal tissue in the primary stage and reinfection stage, an (3) the effect of chemotherapy on the evolution of the infectio This film should be used not only in all medical schools b also in schools of nursing and as a part of the educational pro ess of science students at the college level.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Dissecting Aneurysm of the Aorta with Neurological Involvement. E. N. Weaver. Virginia M. Month. 83:431-437 (Oct.) 1956 [Richmond, Va.].

The author describes five cases of dissecting aneurysm of the aorta in four men between the ages of 33 and 64 years and in a 55-year-old woman. Each of these patients had neurological changes consisting in four of paralysis of the lower extremities, right hemiparesis and a right homonymous hemianopsia, weakness and numbness of the right leg, and weakness of both legs respectively. The neurological changes, which were produced by ischemia of some part of the nervous system as a result of the aortic dissection, emphasized the dominance of neuropathology as the basis of the patients' symptoms. A dissecting aortic aneurysm should be considered in patients who experience sudden severe and unexplained chest, abdominal, back, or leg pain with bizarre radiations and associated neurological signs and symptoms. All five patients died, and autopsy was performed in four. Death occurred as a result of rupture of the aneurysm into the pericardium, the thoracic cavity, or the abdominal cavity. One patient had repeated ruptures and lived for almost five months from the time of onset of his illness. The importance of developing a clinical consciousness of this condition with early diagnosis is emphasized, since many of these lesions are amenable to treatment.

Clinical Consideration on Arterial Embolism and Valvular Misfunction. G. Micheli-Pellegrini and P. R. Lapi. Sett. Med. 44:344-349 (July 15) 1956 (In Italian) [Florence, Italy].

The authors studied arterial embolism in 895 cases of rheumatic valvular disease of the heart. Embolism was found in 38 patients (4.2%). Twenty-nine patients had cerebral embolism, 19 on the right side and 10 on the left side. Two had it in the left arm, one in the right arm, two in the bifurcation of the common iliac, four in the left leg, one in the right leg, and one in the mesentery. The patients were mostly between the ages of 40 and 50 years. There were 33 women and 5 men. It is possible that endocrinal and vegetative factors, the balance of which is less stable in women than in men, may play an important role in causing embolism. Physiological changes in genital function seem to influence the general course of heart disease. The authors noticed in the past history of five patients that the detachment of the embolus coincided with the premenstrual period. Arterial embolism was noticed mainly in patients with valvular mitral disease. Autopsy in five patients showed severe mitral stenosis. Embolism rarely occurred in the first 15 years of the heart disease. Bouillaud's disease was the type of rheumatic disease chiefly responsible for valvular misfunction.

A Study of Serum Lipoproteins in Normal and Atherosclerotic Patients by Paper Electrophoretic Techniques. W. P. Jencks, M. R. Hyatt, M. R. Jetton and others. J. Clin. Invest. 35:980-990 (Sept.) 1956 [New York].

Studies were made to test the large-scale application of two relatively simple methods for the estimation of electrophoretically separated serum lipoproteins by measurement of their cholesterol content and dye-binding capacity. The results of these two methods were compared with each other and with ultracentrifugal methods, the aim being to obtain further confirmation of the association of serum lipoprotein abnormalities with atherosclerosis. Both healthy and hospitalized control groups were used to lessen the possibility that any observed abnormalities might be the result of illness, medication, diet, or restricted activity rather than of atherosclerosis *per se*. A standardized technique for the estimation of serum lipoproteins separated by paper electrophoresis gave results comparable to those of cholesterol determinations on these liproproteins and of ultracentrifugal analysis of lipoproteins at a density of 1.21. No appreciable difference in lipoprotein concentration or distribution, measured by paper electrophoretic techniques, was found between the serums of 68 healthy male Army officers and the serums of 65 patients hospitalized with diseases not associated with atherosclerosis or abnormalities in lipid metabolism. Analyses of serums from 77 men with atherosclerosis, as judged by a history of myocardial infarction, showed a significant drop in alpha lipoprotein and increase in beta lipoprotein, resulting in a decreased ratio of alpha to total lipoprotein in these serums as compared to those of the control groups. Elevations in total cholesterol and total lipid dye-binding capacity were less significant. The percentage of the total serum cholesterol in the alpha lipoprotein fraction was lower in serums from patients studied from zero to six months than in those studied more than six months after an acute episode of myocardial infarction. The electrophoretic distribution of serum proteins showed greater deviations from normal in the group of hospitalized patients than in the atherosclerotic group. Ultracentrifugal analysis of lipoproteins of Sf 12-20 were less often abnormal than were electrophoretic analyses of the ratio of alpha to total lipoproteins in serums from atherosclerotic patients.

Gastric Ulcers: Review of 100 Cases. J. H. Geddes, W. N. Downe and J. A. Taylor. Canad. M.A.J. 75:550-554 (Oct. 1) 1956 [Toronto, Canada].

One hundred patients with gastric ulcer were treated at the Westminster Hospital in London, Ontario, between 1946 and 1952. Thirty patients were treated surgically and 70 were treated medically. The reasons for operation in the surgically treated patients were suspected malignancy in 14, recurrent ulcer in 13, and hemorrhage in 3. With the exception of six, all had subtotal gastrectomies. Only one of the 30 patients treated surgically was found to have carcinoma of the stomach. All medically treated patients were followed up for from two to seven years and none of them had any evidence of gastric malignancy. Twenty of the 100 patients have died since the diagnosis of gastric ulcer was made, and none of them died of gastric neoplasm. These results seem to vindicate the authors' present method of treatment for gastric ulcers, consisting of three to six weeks of intensive medical management in hospital in an attempt to arrive at an opinion concerning the question of malignancy of the ulcer. Clinical and radiological evidences of healing were considered the most important factor in deciding the nature of the ulcer. Other aids employed were the degree of gastric acidity, gastroscopic appearance, and cytology of gastric washings, when available. At the end of three weeks patients were again examined roentgenologically, and if healing was complete the ulcer was considered benign. If healing was incomplete, medical treatment was continued for three more weeks, followed by another barium meal. If the latter showed continued evidence of ulceration, the ulcer was considered malignant and surgery recommended. All patients with ulcers deemed benign were advised to have a barium meal every three to six months for two years.

It would appear that, with careful evaluation of a gastric ulcer in a patient hospitalized for a period of from three to six weeks, an error of 3% or less can be expected. Partial gastrectomy, the surgical treatment of choice for gastric ulcers, has a comparable mortality rate and in addition a definite morbidity of 10%. It is concluded that treatment of patients with gastric ulceration should be individualized, that surgery is not warranted for all patients with gastric ulcer, and that as a rule it should not be carried out before an earnest and careful attempt

---

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1947 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

has been made to determine whether benignity or malignancy exists. Surgery should be carried out as soon as possible in all patients with recurrent ulcer, ulcer on the *greater curvature*, pyloric obstruction, hemorrhage, and perforation.

The Superior Vena Caval Syndrome: Report of 21 Cases. E. A. Calkins. Dis. Chest. 30:404-411 (Oct.) 1956 [Chicago].

Twelve men and nine women between the ages of 41 and 83 years with superior vena caval obstruction were admitted to the Los Angeles County General Hospital between 1947 and 1954. Clinical evidence of superior vena caval obstruction consisted of swelling of the neck, face, and arms and extensive venous collateral circulation over the chest and abdomen with downward flow of blood. In addition, 9 of the 21 patients had shortness of breath and cyanosis of the upper extremities. Arm venous pressure readings were obtained in eight patients with a range of from 250 to 800 mm. sodium chloride solution and an average of 386 mm. Only four pressure readings were obtained from the patients' lower extremities, showing an average of 165 mm. with sodium chloride solution. Arm-to-tongue circulation time averaging 34 seconds was determined with the aid of dehydrocholic acid (Decholin) in six patients. Arm-to-lung time averaging seven seconds was determined with the use of ether in three patients. In four patients angiograms illustrated superior caval or innominate obstruction. The superior vena caval syndrome was caused by bronchogenic carcinoma in 11 patients, by aortic aneurysm in 2, by substernal thyroid in 2, and by undiagnosed mediastinal tumors, nodes, or granulomas in 6. Fifteen patients died, 11 as a result of bronchogenic carcinoma. Six with remission of symptoms or no progression were discharged.

A review of the literature suggests that the major causative factor is bronchogenic carcinoma, which may involve the superior vena cava in from 10 to 15% of the patients, with a generally unfavorable prognosis. With increased knowledge and use of vessel grafting the prognosis is brighter for those in whom the obstruction of the superior vena cava is not caused by a malignant tumor or an aortic aneurysm. Some definite trends were noticed in the author's small series of cases. In contrast to the reports in the literature the predominance of men in the ratio of men to women was reduced from 75% to 57%. The age of the patients appeared to increase and so did the incidence of bronchogenic carcinoma as a causative factor. The average venous pressure in the arms may exceed that in the legs by more than 200 mm. sodium chloride solution.

I^{131}-Labeled Fat in the Study of Intestinal Absorption. J. M. Ruffin, W. W. Shingleton, G. J. Baylin and others. New England J. Med. 255:594-597 (Sept. 27) 1956 [Boston].

Characteristic and reproducible curves of blood levels of radioiodine (I^{131}) have been demonstrated with the use of both radioactive-tagged albumin and radioactive-tagged fat. This method of study was applied to patients with a variety of disorders of the gastrointestinal tract to determine whether their radioactive blood levels and fecal content differed significantly from those found in normal persons. A cold emulsion and a "hot" emulsion were prepared. The cold emulsion consisted of 200 ml. of peanut oil, 200 ml. of water and 15 ml. of Tween 80. The "hot" emulsion consisted of 45 ml. of peanut oil, 5 ml. of I^{131}-labeled glycerol trioleate (2.0 mc. of I^{131}), 50 ml. of water, and 4 ml. of Tween 80. Each emulsion was prepared by mixing of the ingredients in a Waring blender for 15 minutes. Each patient, in a fasting state, was given a test meal consisting of the following: the volume of "hot" emulsion that contained 25μc of I^{131} to which was added enough cold emulsion to make a total of 1 ml. per kilogram of body weight. Twenty grams of barium sulfate was added to the test meal, and the entire contents mixed. The subject drank the test meal. The container was rinsed twice with 50 ml. of tepid water, which was likewise ingested. The container was assayed for residual I^{131}. Twenty drops of Lugol's solution was given immediately after the test meal. Two milliliters of venous blood was withdrawn at hourly intervals for six hours after ingestion of the test meal. Each sample was placed in a separate tube and assayed for I^{131} content in a scintillation crystal-well counter.

The 180 patients tested with the labeled fat included 44 with functional gastrointestinal disturbances; 57 with gastrointestinal diseases (including pancreatitis, carcinoma of the pancreas, sprue, enteritis, colitis, and hepatic cirrhosis); and 79 who had been operated on for peptic ulcer. In the group of patients with functional gastrointestinal disturbances, the blood levels and fecal excretion were within normal limits, while patients who had disease of the small intestine, regardless of cause, invariably had profound lowering of their blood levels and marked increase in radioactive content of the stool. The patients with sprue in clinical remission had completely normal blood and stool values, pointing to the reversibility of the pathological process. Patients with disease of the colon only had normal absorption. This was also true of patients with cirrhosis of the liver. The evidence in patients with disease of the pancreas points to faulty digestion rather than to an intrinsic error of absorption: 12 of the 13 patients with carcinoma of the pancreas had abnormal levels. Fifty-three per cent of the patients who had undergone gastric surgery for peptic ulcer showed significant lowering of the blood curves and increase in radioactive content of the stool. It is well known that appreciable weight loss is fairly common in postresection and postvagotomy patients; these findings suggest that one of the factors causing weight loss in this group of patients is impaired fat absorption.

Superior Vena Cava Draining into Left Atrium: Another Cause for Left Ventricular Hypertrophy with Cyanotic Congenital Heart Disease. H. Tuchman, J. F. Brown, J. H. Huston and others. Am. J. Med. 21:481-484 (Sept.) 1956 [New York].

A 15-year-old boy was hospitalized in February, 1955, complaining of fatigue and unexplained fever. In October, 1954, his physician had found that polycythemia was present. In February, 1955, the patient appeared to be moderately plethoric with cyanosis of the acral parts. Down-curving of the finger nails without actual clubbing was noted. The conjunctival and retinal vessels were engorged. The left border of cardiac dulness was at the midclavicular line. The liver was palpable 3 cm. below the costal margin, and the spleen was just palpable. Cardiac catheterization revealed a superior vena cava that drained into the left atrium. The impression was that the patient had a single vascular anomaly in which the superior vena cava entered directly into the left atrium. Surgical exploration confirmed this. The aorta and the left ventricle were enlarged. The right atrial appendage was hypertrophied and dilated. Within the pericardium and extending upward from the cephalic end of the right atrium was fibrous remnant of the normal superior vena cava. The patient died 20 hours after the operation.

Postmortem examination confirmed the diagnosis and failed to reveal any other congenital cardiac anomaly. The case is thought to be of interest because it represents another type of cyanotic cardiovascular anomaly producing left ventricular hypertrophy and because the quantity of shunt as calculated here confirms the existing impression that about one-third of the venous return is via the superior vena cava and about two-thirds via the inferior vena cava. The diagnosis should be easily available to all who have access to cardiac catheterization and angiocardiography, and correction by surgery is feasible.

Episodic Stupor Following Portacaval Shunt: Observations on Etiology and Therapy. C. J. Fisher and W. W. Faloon. New England J. Med. 255:589-594 (Sept. 27) 1956 [Boston].

A 58-year-old man was first hospitalized with hematemesis, and a diagnosis of portal cirrhosis with bleeding esophageal varices was made. He had a history of chronic alcoholism associated with a poor dietary intake for many years. A splenorenal shunt was performed. Six months later he was readmitted with gastrointestinal bleeding, and x-ray study again revealed esophageal varices. A portacaval shunt was performed. Twelve episodes of coma or deep stupor were observed in this patient. They could be related to intolerance to more than 25 gm. of dietary protein ingested orally, to protein hydrolysate infusions, or to oral administration of ammonium chloride. The sequence of the development of coma included the stages of flapping tremor of the outstretched extremities, usually associated with mental confusion, gradually increasing stupor, and coma. During recovery the sequence of events was reversed.

His mental status, even when he was "alert," was markedly abnormal. No clear-cut correlation between the clinical condition and the venous-blood ammonia levels was observed. Neomycin therapy resulted in marked reduction in blood ammonia levels and enabled this patient to ingest a regular hospital diet containing approximately 90 gm. of protein.

Stable and Brittle Diabetes. J. G. Alivisatos and E. P. McCullagh. Am. J. Med. 21:344-357 (Sept.) 1956 [New York].

There are patients with long-standing diabetes in whom the blood sugar values are consistently fluctuating, in spite of attempts to obtain normoglycemic control, and who nevertheless have only very slight degenerative complications. The authors believe that this is due to uncertainties as to definition of the term "control" and to the failure to recognize the existence of two distinct types of diabetes mellitus, the stable and the brittle. They apply the term stable diabetes to patients who are insulin-insensitive and brittle diabetes to those who are insulin-sensitive. Another distinct metabolic feature of patients with brittle diabetes is that ketosis develops rapidly and repeatedly despite attempts to establish normoglycemic control. If insulin is not administered in adequate doses, diabetic coma will develop. Ketosis indicates increased catabolism of fat. These disturbances in the carbohydrate and fat metabolisms in patients with brittle diabetes suggest that this type of diabetes is a separate metabolic entity. This study was undertaken to ascertain whether or not other clinical or biochemical features distinguish brittle from stable diabetes and whether the incidence of late degenerative complications is different in these two groups of patients. One hundred seventy-two patients were studied, but only 149 fulfilled all the criteria for classification in one or the other of the two groups. There were 70 patients with brittle diabetes and 79 with stable diabetes. When distribution curves of the over-all blood sugar values were plotted, it was found that patients with brittle diabetes had a V-shaped curve indicating that these patients have a high frequency of blood sugar values in the two extreme ranges, the very low (less than 120 mg. per 100 cc.) and the very high (above 200 mg. per 100 cc.). In patients with stable diabetes the blood sugar curve is a descending line. Degenerative complications were more frequent in patients with stable diabetes than in those with brittle diabetes. The incidence of severe diabetic retinopathy was low in adult patients with brittle diabetes of long standing. Patients with stable diabetes with poor control showed a significantly higher incidence of late degenerative complications than patients with stable diabetes with good control.

Treatment of Severe Tetanus with d-Tubocurarine Chloride and Intermittent Positive-Pressure Respiration. A. C. Smith, E. E. Hill and J. A. Hopson. Lancet 2:550-552 (Sept. 15) 1956 [London, England].

Intermittent positive-pressure respiration in association with some method of preventing spasm is an advance in the treatment of severe tetanus. The patient presented, a 7-year-old boy, had an especially severe form of tetanus. He had been cut on the forehead by a sharpened stick used as an arrow. His doctor treated the wound, which was superficial, but gave no antitetanic serum because of an allergic reaction to a dose of serum given 18 months before. The wound became infected and was treated with penicillin and aureomycin. Four days after the injury the right side of the patient's face became stiff and trismus developed. The patient was treated for 26 days with paralysing doses of curare (up to 640 mg. in 24 hours to a total dose of 7,640 mg.), and respiration was maintained by intermittent positive pressure from a Radcliffe respiration pump. Chloral hydrate was given to prevent any memory of the period. The patient made a complete recovery.

The d-tubocurarine was chosen as the relaxant for two reasons: 1. Absolute muscle relaxation can always be obtained if enough curare is given. 2. Curare has been successfully used in other cases. The standard dose of curare in this patient was 15 mg. given intravenously, and this dose abolished all muscular movement for a time. Spasms, modified to myoclonic twitching, recurred after from 20 to 30 minutes, and more curare was given when these spasms became obvious. The authors gained the impression that the occurrence of even these modified spasms adversely affected the patient's general condition, and they would probably be even more lavish with the dosage of curare in a future case. The diet was based on an intake of 72 oz. of milk daily with additional glucose and Casilan to provide 1,750 calories. The high-protein diet usually given to these patients was not given, because this patient's blood-urea level never fell below 50 mg. per 100 ml. The patient's voracious appetite after normal feeding was resumed suggests that this calorie intake was insufficient. Penicillin and streptomycin were given for the first week against the causal organism and prophylactically against chest complications. Sulphadimidine in small doses was given for the rest of his illness and, in association with physiotherapy and changes of posture, controlled his chest infection. Promethazine was given to minimize allergic reactions.

Infection of Volunteers by a Virus (A. P. C. Type 1) Isolated from Human Adenoid Tissue. A. T. Roden, H. G. Pereira and D. M. Chaproniere. Lancet 2:592-596 (Sept. 22) 1956 [London, England].

A strain of type 1 APC (adenoidal-pharyngeal-conjunctival) virus was administered by nasal instillation to 11 volunteers. Garglings taken on the second, fourth, and sixth days after the instillation were examined for the presence of type 1 virus, which was recovered from none of the volunteers on the second day and from four of them on the fourth or sixth day. Acute pharyngitis developed on the fourth and fifth days in two of the volunteers from whom the virus was recovered. The remaining volunteers showed no clinical signs of infection. Paired serums were tested for neutralizing and complement-fixing antibodies for APC viruses of tyypes 1 to 6. Neutralizing antibodies for type 1 virus were not detected in the preadministration serums of any of the four volunteers from whom the virus was subsequently recovered but were present to varying titers in the preadministration serums of the remainder. All volunteers from whom the virus was recovered showed definite increases in neutralizing antibodies for the homologous type and variable responses to the heterologous types. Three volunteers from whom no virus was isolated showed increases in neutralizing antibodies. Rises in complement-fixing antibodies were observed only in the group of volunteers from whom virus was recovered and were greatest in the two volunteers who showed clinical evidence of infection.

Polycythemia and Hypernephroma. E. Noe. Nord. med. 56: 1164-1165 (Aug. 18) 1956 (In Norwegian) [Stockholm, Sweden].

In eight of the nine previously published cases of polycythemia and hypernephroma the finding of hematuria made possible the diagnosis of renal tumor during life. In the three patients operated on the polycythemia disappeared after nephrectomy. The polycythemia is thought to be secondary to the renal tumor. There is no clearly formulated theory as to the mechanism in this connection. In the case reported, in a man aged 55 with pleural exudate, there were no symptoms from the urinary tract to indicate urography. The diagnosis of polycythemia was based on the hemoglobin, red blood cell, and thrombocyte values, together with the typical sternal punctate. Cerebral symptoms that set in were ascribed to cerebral thrombosis, and anticoagulant treatment was applied. The patient died in coma and hyperthermia. Autopsy revealed a tumor of the right kidney and tumors of similar appearance in the right pleura and right cerebral hemisphere. The microscopic picture showed hypernephroma. The pleural exudate proved to be an expression of pleural metastasis of the hypernephroma.

Pneumoperitoneum in the Management of Esophageal Hiatus Hernia: A New Diagnostic and Therapeutic Procedure. B. Masel, W. Cooper and F. Glenn. J. Am. M. Women's A. 11:299-315 (Sept.) 1956 [New York].

Pneumoperitoneum was used as a new diagnostic and therapeutic procedure in five patients with esophageal hiatus hernia. The pneumoperitoneum established the differential diagnosis between angina from coronary arterial insufficiency and angina produced by hiatus hernia and also between dyspepsia caused by gallbladder disease and dyspepsia due to hiatus hernia. The pneumoperitoneum controlled hemorrhage, vomiting, rumination, and dyspepsia caused by hiatus hernia. It is induced in the following manner: The patient is placed in the supine position. The abdomen is shaved and prepared with three applications of zephiran. A point midway between the left costal margin and the umbilicus is infiltrated with 2% procaine solution. A 19-gauge needle, 1.75 in. long, attached to a 10-cc. syringe, is introduced into the abdominal wall to a point where the anterior rectus sheath is encountered. A needle guard or a clamp is adjusted to the needle to permit safe advancement for another 1.5 cm. through the rectus muscle, the posterior rectus sheath, and the peritoneum. As the needle passes through the peritoneum, the patient feels a slight sticking pain. Five cubic centimeters of novocain is introduced into the peritoneal cavity to test the free flow and to make certain that the needle tip is within the peritoneal cavity. A three way stopcock is attached, and small amounts of room air are introduced to test the free flow into the peritoneal cavity. The 10-cc. syringe is replaced by one that holds 50 cc., and about 1,000 cc. of air is injected. Codeine phosphate is given every four hours for four doses to control the shoulder pain caused by the air beneath the diaphragm.

The peritoneum proved of particular value in aged patients with hiatus hernia. It did not produce recognizable interference with the cardiopulmonary function and did not complicate the operative management of these patients. On the contrary, the great amount of space beneath the stretched and elevated left diaphragm facilitated the repair of the diaphragm and the manipulation of the stomach, esophagus, spleen, and left lobe of the liver. Hiatus hernia may cause left flank pain, clinically indistinguishable from renal pain. The elderly patient with a symptomatic hiatus hernia may be treated on an ambulatory basis in a hiatus hernia pneumoperitoneum clinic, provided the initial injection of air is given in the hospital under close supervision. The clinical course and the signs, symptoms, diagnosis, and pathological changes of esophageal hiatus hernia are reviewed. The authors suggest that the development of paraesophageal and sliding hiatus hernia can be attributed to the loss of the normal vis-a-tergo of the tissues at the esophageal hiatus and the effects on the stomach of a rising and falling intrathoracic pressure associated with coughing, sneezing, and defecation. Hiatus hernia is often associated with chronic cholecystitis, cholelithiasis, and peptic ulcer.

Treatment of Uremic Nausea and Vomiting with Chlorpromazine (Largactil). P. Eilersen. Ugesk. læger. 118:953-954 (Aug. 16) 1956 (In Danish) [Copenhagen, Denmark].

In Bispebjerg Hospital intractable nausea and vomiting in 21 patients with uremia due to chronic nephritis, nephrosclerosis, or chronic pyelonephritis were treated by peroral administration of Largactil. The dosage was 25 mg. four times daily except in two instances, in which the dosage was 50 mg. four times daily. The symptoms ceased in nine patients, five were improved, and in seven there was no change. Two of the nine patients had been greatly troubled by hiccups, which ended at once on the Largactil treatment. The appetite was improved in all the improved patients. In spite of subjective improvement, the blood urea level was not reduced during the period of treatment. Nine patients with cancer metastases and four with other diseases were also treated with chlorpromazine because of nausea and vomiting. In four of the first group the symptoms disappeared entirely, while three were improved and two unchanged; in three of the second group the symptoms ceased, and the fourth patient was improved. While no side-effects of chlorpromazine were seen, the substance should, on account of the side-effects described in the literature, be reserved for the treatment of continuous nausea and vomiting in incurable patients.

Herpes Zoster and Liver Diseases. W. Siede. Deutsche med. Wchnschr. 81:1401-1402 (Aug. 31) 1956 (In German) [Stuttgart, Germany].

Siede reports on seven patients in whom herpes zoster occurred in association with liver disorders. The liver was more or less enlarged and its consistency increased in all seven patients. Liver biopsy in two patients revealed the histological characteristics of involvement of the hepatic mesenchyma, with proliferation and chronic inflammatory infiltration of the periportal tissues. This process also involved some of the peripheral lobules. The stellate Kupffer's cells were increased. The hepatic cells showed a granular or vacuolated protoplasm, and here and there a cell membrane and nuclear synthesis. The protein tests indicated pathological changes, and electrophoresis revealed a constellation of the protein fractions characteristic of hepatic impairment. Liver-function tests carried out during the acute stage also indicated a pathological condition. Only one of the patients was definitely jaundiced, but three were subicteric. In five of the patients the hepatitis subsided within weeks; in one it persisted for eight months; and the seventh still has signs of chronic hepatitis after two years.

Herpes zoster is apparently an infectious disease caused by a virus. The question arises whether the concurrence of herpes zoster and hepatitis in the cases presented was fortuitous or whether there was an etiopathogenetic relationship. In some of the patients the herpes zoster appeared in the segments that correspond to the sympathetic innervation of the liver. This might suggest that the virus hepatitis produced a site of lessened resistance; however, this would presuppose that the hepatitis preceded the herpes zoster, and this occurred in only one of the patients, whereas in the others the appearance of the two disorders coincided. The author believes that both diseases can be caused by the same virus. A number of virus diseases are known to cause disorders in several organ systems. As a typical example he mentions glandular fever, which involves not only the lymphatic apparatus but occasionally also the liver and the central nervous system. The same applies to primary atypical pneumonia. More recently it has been observed that the virus diseases of the central nervous system may show the same behavior. Thus, involvement of liver and spleen and even hepatitis with jaundice has been observed in poliomyelitis. When hepatitis appears concurrently with herpes zoster, it is possible that a zoster virus with hepatotropic properties is the cause.

Bleeding Peptic Ulcer: A Clinical Study of 511 Cases. A. Aldman and S. Wallensten. Acta med. scandinav. 155:205-222 (No. 3) 1956 (In English) [Stockholm, Sweden].

Four hundred five men and 106 women between the ages of 30 and 80 years with bleeding gastroduodenal ulcers were treated at the medical and surgical departments of Serafimerlasarettet in Stockholm, Sweden, between 1942 and 1953. Two hundred thirty of the 511 patients had mild hemorrhage and 281 severe hemorrhage. Hemoglobin and red blood cell determinations were used as criteria of the seriousness of the hemorrhage. Patients with a drop of hemoglobin to 50% or less and a red blood cell count of 2 million or less were considered as having severe hemorrhage and all the others as having a mild hemorrhage. The seriousness of the hemorrhage and the measures to be taken were determined largely by the volume and the rate of bleeding. The type of the ulcer, the age of the patient, and the duration of the condition seemed to be of less importance wtih respect to prognosis. The patient's general condition at the time of admission or at some other arbitrarily chosen time did not provide any reliable basis for assessing the prognosis.

Conservative therapy was indicated in most of the patients. There was a gradual increase in the number and the volume of blood transfusions in the course of the later years of the 10-year period. Partial gastrectomy was performed only in 22 patients whose lives were threatened by the hemorrhage despite generous blood transfusions. X-ray examination was performed immediately on admission in 57 patients with bleeding ulcers. In 41 patients it revealed a niche in the duodenum or stomach from which the hemorrhage was believed to originate. Deformation of the duodenal bulb suggested the presence of a bleeding ulcer in 10 patients. There were only six patients in whom the roentgenograms did not give any information with regard to the source of the bleeding. In 45 of the 57 patients the x-ray examination had to be performed with the patient in recumbent position; in none of them was the hemorrhage increased by the x-ray examination.

Twenty-three of the 511 patients died, a mortality rate of 4.5%. Only one of the 230 patients with slight hemorrhage died, but 22 (7.8%) of the 281 patients with severe hemorrhage died. With more abundant blood transfusions the mortality rate was reduced from 7% during the period from 1942 to 1945 to 3% during that from 1950 to 1953. The mortality rate in the patients subjected to partial gastrectomy also decreased with the introduction of modern shock therapy and improved techniques of anesthesia. In patients with massive hemorrhage the blood lost should be replaced as rapidly as possible by ample blood transfusions; if despite this measure the bleeding does not stop and the life of the patient is threatened, surgical intervention should be considered and it should be performed as soon as possible after the onset of the hemorrhage. Speedy surgical intervention is particularly advisable in patients over 60 years of age.

Pseudomembranous Enterocolitis and Antibiotics. C. R. Newman. Ann. Int. Med. 45:409-444 (Sept.) 1956 [Lancaster, Pa.]

Newman discusses pseudomembranous enterocolitis on the basis of many literature reports, and he describes the histories and autopsy studies of 12 patients with this disease observed in several small hospitals. Pseudomembranous inflammation of the intestine has been recognized for over a century, but during recent years there has been an apparent increase in its incidence. There is disagreement regarding the role of antibiotics in the production of this condition. A wide variety of causes, such as inorganic or metabolic poisons, bacterial infection, or mechanical factors, may play a part in it. Antibiotics appear to play a significant part in its development in many instances. They cannot, however, be solely responsible for all cases. Multiple factors are probably responsible, even in cases in which antibiotics have been administered. Either superinfection or the development of antibiotic-resistant organisms appears to be the greatest hazard in the use of the antibiotics. Superinfection results from a disturbance in the normal bacterial flora of the body cavities. The reciprocal inhibitory effect is therefore destroyed or lessened. Superinfection may involve the same organ of the body in which the primary infection occurred or a different one. Organisms hitherto unlikely to produce serious disease may occasionally cause a secondary infection more serious than the primary disease and may sometimes cause death. These secondary infections respond poorly to known antibiotics. They occur most frequently from two to five days after initiation of antibiotic therapy, the patient appearing to have a relapse after an initial period of improvement. Frequent cultural studies are necessary to foresee or promptly recognize a serious superinfection.

There is evidence that micrococci (staphylococci) play a major role in the development of severe pseudomembranous enterocolitis, because they are much more adaptable to antibiotics than is the normal intestinal flora. Carriers in a community or hospital where many patients have been treated with antibiotics are probably the source of these resistant organisms. The micrococcic enterotoxin very probably leads to the formation of a pseudomembrane by its direct irritant action and presumably also produces generalized systemic effects. Although erythromycin offers a great deal of help in treatment, micrococci seem gradually to become resistant to this drug also. Enterocolitis should be thought of whenever a relapse occurs during an illness, after injury, or after an operation, particularly when antibiotics have been used. If diarrhea, paralytic ileus, fever, dehydration, loss of blood volume, and collapse are present, vigorous treatment is necessary. Reports indicate a rising index of suspicion, inasmuch as more cases are being diagnosed before death, and early treatment will doubtless produce better results. Efforts should be made to prevent the enterocolitis that is related to the use of antibiotics by (1) preventing the development of organisms that are resistant to antibiotics and (2) by detecting resistant organisms before severe untoward reactions occur.

The Importance of the Fractional Serum Bilirubin Determination in Clinical Medicine. C. J. Watson. Ann. Int. Med. 45:351-368 (Sept.) 1956 [Lancaster, Pa.].

The observations of Hijmans van den Bergh on the essential difference between the prompt direct and the delayed or indirect reacting fractions of the serum bilirubin are supported by recent observations, especially those of Cole and Lathe on the polar, or water-soluble, and nonpolar, or water-insoluble, character of the two types. The hitherto undescribed bilirubin sulfate is a polar compound exhibiting a prompt direct diazo reaction. The ease with which nonpolar, crystalline bilirubin can be isolated from sources such as bile, in which the initial behavior is almost entirely polar, is more in accord with a complex than an intrinsic molecular difference. The validity of measurement of the direct reacting bilirubin at one minute deserves more emphasis. Measurement at 30 minutes includes significant fractions of the delayed, indirect, or nonpolar bilirubin. This is well demonstrated when the values at 1 and 30 minutes and the total (after alcohol), obtained with serum from patients with uncomplicated hemolytic jaundice, are compared with the amounts of polar and nonpolar bilirubin from the same samples, separated by reverse phase chromatography. The correspondence between one-minute and polar bilirubin is excellent. The 30-minute direct bilirubin, however, clearly includes nonpolar bilirubin.

During the last 10 years the fractional serum bilirubin determination, one-minute and total, has been used routinely in the University of Minnesota Hospital and the Minneapolis Veterans Hospital. The author emphasizes that the experiences accumulated during these 10 years with the determination of one-minute and total bilirubin and bilirubin ratios in relation to the clinical problems of jaundice, liver and biliary tract disease, and anemia, has fully confirmed the usefulness of this fractionation. The following points are cited as evidence that the fractionation often enhances the value of the serum bilirubin studies. 1. The one-minute bilirubin is often increased significantly within a normal value for total bilirubin. This has been observed especially in patients with early hepatitis, cirrhosis, common-duct stone, and hepatic carcinomatosis. The finding is of value in revealing an abnormality and, while not differential in itself, often points to the presence of disease of the liver or biliary tract. 2. Low bilirubin ratios in patients with elevated total serum bilirubin are indicative of retention jaundice in varying degree. The lowest ratios (<20%) are characteristic of hemolytic disease or constitutional hepatic dysfunction of the Gilbert type. The Dubin-Johnson type of jaundice and hepatic dysfunction generally exhibits ratios above 40%, most often in the range characteristic of ordinary regurgitation jaundice. 3. While the majority of patients with jaundice due to parenchymal liver disease have bilirubin ratios in the same general range as those found in cases of biliary obstruction (45 to 80%), there is a significant number of patients with diffuse liver disease in whom ratios below 40% are encountered. In the range of 35 to 40% there is small likelihood of confusion with (benign) biliary obstruction, and below 35% almost none.

SURGERY

Mitral Valvotomy: A Progress Report. R. W. D. Turner and H. R. L. Fraser. Lancet 2:525-531 (Sept. 15) and Lancet 2:587-592 (Sept. 22) 1956 [London, England].

The first 250 patients from the cardiac department of the Weston General Hospital, Edinburgh, who were subjected to mitral valvotomy were analyzed with regard to various factors that may influence the operative result. These patients were all followed for more than 12 months: 202 for more than two years, 116 for more than three years, 37 for more than four years, and 9 for more than five years. Ninety-seven per cent had either tight (finger-tip) or fairly tight (terminal phalanx) stenosis. The ages of the patients ranged from 16 to 60, and 29 were aged more than 50. Forty-four per cent had auricular fibrillation, 27% had calcification of the mitral valve, and in 19% an intracardiac clot was found at operation. Two hundred fifty other patients with mitral stenosis were seen at about the same time and not advised to have an operation, because their condition was either too mild, too severe, or complex. The electrocardiographic signs of right ventricular hypertrophy are summarized, and the value of right-side V leads is pointed out. In association with signs of uncomplicated mitral stenosis evidence of right ventricular hypertrophy invariably indicated that the stenosis was sufficiently severe to warrant operation. Some of the radiological aspects of mitral disease are discussed, and emphasis is laid on the significance of the transverse lines, which are believed to indicate distended lymphatics. Cardiac catheterization is rarely required in the assessment for operation. The operative mortality was 8%. In patients aged less than 50, even with auricular fibrillation and moderate enlargement, it was 5%. There have been only two deaths in the last 100 cases. Seven patients died from 1 to 39 months after operation.

The results were good or very good in 70% and fairly good in 10% of the patients. Analysis of the poor results revealed that systemic embolism, inadequate valvotomy, and traumatic mitral incompetence were the surgical factors concerned. The larger the heart the less likely is a good operative result to be achieved or maintained, and the least hopeful combination is a large heart with auricular fibrillation and without electrocardiographic evidence of right ventricular hypertrophy. Auricular fibrillation, enlargement, calcification of the valve, and intracardiac clot are frequent in patients over 50; consequently the operative risk is greater and the proportion of good results smaller. Nevertheless, a good result was obtained in 17 of 29 patients aged more than 50 and in 7 of 8 patients without these adverse factors. The incidence of auricular fibrillation increases with age and with heart size. The mitral valve was calcified in 27% of the patients who came to operation. Its incidence increased with age and was greater in males. Disadvantages of calcification are that effective splitting of the commissures may be impossible and attempts to achieve it increase the operative risk; good function of the valve may not be achieved despite good splitting of the commissures; and calcific embolism may take place into the systemic circulation. Despite these facts good results were obtained in more than half the patients with severe calcification. Aortic stenosis does not contraindicate mitral valvotomy for mitral stenosis, because aortic valvotomy can be carried out at the same thoracotomy. Severe cardiac cirrhosis of the liver contraindicates operation. In pregnancy operation is advised only if it is clear from the history that there was progressive dyspnea before pregnancy and that valvotomy would have been indicated in any event. Although the operative result is largely determined by the local pathological changes in the mitral valve, most patients are still being referred for operation after the optimal time has passed. Operation should be considered whenever symptoms are progressive and should be carried out unless contraindications are present.

Surgical Treatment of Cancer of the Thyroid. H. A. Kingsbury. Am. Surgeon. 22:847-856 (Sept.) 1956 [Baltimore].

Ninety-one patients with histologically proved thyroid cancer were treated at the Roosevelt Hospital in New York during the 25-year period from 1930 to 1955. Six patients could not be traced after discharge from the hospital. The remaining 85 have been followed up for periods of up to 23 years. The 91 patients were operated on by 20 different surgeons and a number of residents. The extent of operation varied with the attitude of the surgeon in charge. Among 38 patients with papillary adenocarcinoma who have been followed up for from 1 to 23 years since operation, 3 are known to have died of thyroid cancer. Two of the deaths occurred seven years after the primary operation. Of 23 patients with the diagnosis of follicular and alveolar adenocarcinoma, 4 have died. This includes three patients in whom the disease was far advanced at the time of surgery. One patient was lost to follow-up. There were two deaths among nine patients with Hürthle cell carcinoma. One patient died 13 years after the primary operation. The other had generalized metastases at the time of operation and died two months later. Among seven patients with solid adenocarcinoma, five were in an advanced stage of the disease and received palliative treatment only. Six of the seven died. Of 10 patients with giant and spindle cell carcinoma, 9 died within 18 months. One is still alive, despite numerous recurrences during the past 11 years. Sarcoma of the thyroid gland in four patients was uniformly fatal in a short time.

Vagotomy and Gastroenterostomy in the Surgical Treatment of Duodenal Ulcer. K. R. Trueman and D. L. Kippen. Canad. M. A. J. 75:547-550 (Oct. 1) 1956 [Toronto, Canada].

Twenty-five women and 80 men between the ages of 22 and 78 years with intractable or complicated duodenal ulcer underwent vagotomy and posterior gastroenterostomy at the Winnipeg Clinic in Canada, between May, 1946, and December, 1953. Symptoms had been present for an average of 12 years. Intractable pain was present in 101 patients; it was accompanied by hemorrhage in 41, perforation in 18, and pyloric obstruction in 15. Ninety-three patients were followed up for from 3 to 10 years. Control of the peptic ulcer by vagotomy and gastroenterostomy was good in 77 patients (82.8%) and fair in 6 (6.4%). Results were poor in 10 patients (10.7%). Recurrence of chronic peptic ulceration was demonstrated in only three patients. Moderate hemorrhage without symptomatic or radiological evidence of chronic peptic ulcer accounted for 3 of the 10 poor results. Although postoperative gastrointestinal disturbances of some degree occurred in 11 patients, they were considered to be undesirable side-effects of the operation in only 5. The other six patients had symptoms referable to an irritable colon, which was present before the operation.

Cancer of Stomach and Gastric Ulcer. J. de M. Grey and L. F. de Moraes. Rev. brasil. cir. 32:91-100 (July) 1956 (In Portuguese) (Rio de Janeiro).

Cancer of the stomach coexisting with gastric or duodenal ulcer is far more frequent than is believed. The ulcers are potentially cancerous. They call for surgical treatment whenever the clinical symptoms and roentgen signs persist or reappear after discontinuance of medical treatment and of diet. The period of waiting before resorting to surgery should be no more than five or six months for a duodenal ulcer and three or four months for a gastric ulcer. Three cases are reported. The first patient had resection for a simple gastric ulcer. Histopathological examination of the removed specimen showed the aspects of an ulcer with cancer developing at the base of the ulcer. The second patient had a clinical and roentgen diagnosis of antral cancer. During laparotomy for subtotal gastrectomy, enlarged lymph nodes were observed at the lesser curvature and the cardia. A total gastrectomy was performed. Histopathological examination did not reveal cancer in the antral tumor, but the lymph nodes proved to be metastases of mucoid carcinoma. The third patient, a man of 70, complained of gastric symptoms of two years' duration. Roentgen examination showed an antral tumor. During laparotomy for subtotal gastrectomy another tumor was observed. It was larger than the antral tumor and was located on the greater curvature and the cardia. Histopathological examination showed two distinct tumors of the same type, without any involved tissue between them. The authors advise early gastrectomy for gastric and duodenal ulcers that do not respond to diet and medical treatment and also for gastric tumors presenting the roentgen appearance of gastric cancer.

Clinical and Pathophysiological Problems of Total Gastrectomy in Patients with Carcinoma of the Stomach. T.-O. Lindenschmidt. Ztschr. klin. Med. 154:200-215 (No. 2) 1956 (In German) [Berlin, Germany].

Thirty-three men of the average age of 56 years and 17 women of the average age of 62 years with advanced carcinoma of the stomach were operated on at the surgical clinic of the University of Hamburg-Eppendorf, Germany, between 1950 and 1954. Forty patients had total gastrectomy and 10 had subtotal gastrectomy with 1, 2, or 3 cm. of stomach left below the cardia. There were 22 operative deaths. Fifteen patients died within from 3 to 36 months after their discharge from the hospital following the operation. Three patients were lost to follow-up. Ten patients are living with an average survival time of 30 months. The tumors invaded all the parietal layers in all the patients. Metastases were found at the operation in the lymph nodes of 6 of the 15 patients who died after their discharge from the hospital. Of the 10 still living, only one had metastases of the lymph nodes of the omentum, which was removed at the operation.

The author is convinced that indications for surgical treatment of advanced carcinoma of the stomach should be widened. There are no reliable historical, clinical, or roentgenologic data excluding operability of the tumor. Subtotal or total gastrectomy, with simultaneous removal of all the suspicious lymph nodes and of the metastasized omentum, if necessary, is required if the size of the tumor is such that the resection, either toward the pylorus or toward the cardia, cannot be made at a distance of at least 5 cm. from the tumor. The simultaneous removal of adjacent organs affected by the tumor must be decided on in the course of the intervention. Pathophysiological considerations do not limit subtotal or total gastrectomy, provided that the patient is given adequate substitution therapy in the preoperative and postoperative period. Such therapy should consist of adequate administration of proteins in order to break through the vicious circle between protein deficiency and enzyme deficiency. Pancreas preparations should be supplied to improve the utilization of proteins and fats. Parenteral iron therapy is indicated in the presence of anemia due to iron deficiency. Vitamin B_{12} and folic acid therapy are indicated in the presence of megaloblastic anemia. Vitamin B complex therapy is important for the prevention or treatment of manifestations of vitamin B deficiency after total gastrectomy, such as glossitis, pharyngitis, cheilitis, and esophagitis. Total gastrectomy is not indicated in patients in whom all the adjacent organs, i.e., liver, pancreas, spleen, diaphragm, mesocolon, and colon, have become infiltrated by the carcinoma, requiring such a formidable intervention that only exceptional patients may survive. In addition, the prognosis is not favorable as regards freedom from relapses and metastases in patients with involvement of suprapancreatic and para-aortal lymph nodes. and it is particularly unfavorable in patients in whom the tumor has invaded all of the parietal layers.

Primary Resection of Stomach in Free Perforation of Gastroduodenal Ulcers. R. Baltzersen. Nord. med. 56:1195-1196 (Aug. 23) 1956 (In Norwegian) [Stockholm, Sweden].

In Haukeland Hospital in Bergen 179 cases of free perforation of gastroduodenal ulcers (134 cases of perforated duodenal ulcer, 45 of perforated gastric ulcer) were treated from 1942 to April, 1955, with a total mortality of 9.5%. Primary resection of the stomach according to Billroth 2 or its modifications was done in 118 of the cases, with 5 deaths, all in men with duodenal ulcers. From 1938 to April, 1955, a total of 313 gastroduodenal perforations into the free peritoneal cavity were treated with 32 deaths or a mortalityy of 10.2% Of the 175 patients in whom primary gastric resection was performed, 7, or 4%, died; they were all treated for perforated duodenal ulcer. Only one death occurred in the 67 primary resections performed after 1947, giving an operative mortality of 1.5%. In the 605 gastric resections performed in the same period for nonperforating ulcers the mortality was 1.2%.

Experiences with the Treatment of Acutely Massively Bleeding Peptic Ulcer by Blood Replacement and Gastric Resection. J. D. Stewart, J. H. Cosgriff and J. G. Gray. Surg. Gynec. & Obst. 103: 409-415 (Oct.) 1956 [Chicago].

Immediate blood replacement and early gastric resection has been used by Stewart and associates since January, 1947, in the treatment of patients with massively bleeding peptic ulcer. They review observations on 193 patients on whom 196 operations were performed. Chronic duodenal ulcer, penetrating in nature, was the commonest lesion, while chronic gastric ulcer was second in frequency. Shallow ulcer associated with a brief or nondescript history of ulcer dyspepsia was not uncommon, accounting for approximately 20% of the gastric lesions. In 21 patients the site of bleeding was not satisfactorily determined at operation. During the series of 196 operations on 193 patients, 22 patients were found to have other causes for bleeding. There were 13 malignant lesions of the stomach and 4 of the duodenum and pancreas. Of the 3 patients with hemorrhage from esophageal varices, one had extrahepatic portal bed block, or Banti's syndrome. The appropriate operation was carried out when the true diagnosis became evident in these 22 patients, and at least one of those who had gastric resection for hemorrhagic gastric carcinoma under these circumstances is alive and well over five years later. Subtotal gastrectomy was performed in 186 of the patients.

Twenty-five of the patients died. There were two deaths among the 65 patients less than 50 years old (3%) and 23 (18%) among the 128 patients over 50 years of age. Half of the patients who recovered and three-quarters of those who died had serious associated diseases. There was a high incidence of cardiovascular disease in patients over 50 years of age. The commonest postoperative complications in patients who recovered were wound infection and dehiscence, pulmonary atelectasis, and pneumonia; commonest in those dying were cardiac complications. Dehiscence of the duodenal stump, stomal arrest, transfusion reaction, and postoperative hemorrhage were rare. The average amount of blood given before and during operation was 2,600 cc.

The Management of Ascites with Radioactive Gold. R. J. Ireton and J. C. Ullery. Surg. Gynec. & Obst. 103:437-442 (Oct.) 1956 [Chicago].

Radioactive colloidal gold (Au^{198}) has been used in the treatment of ascites at the Ohio University Hospital since 1952. The group treated included 35 patients with proved ascites secondary to tumor. Three of these patients received a second Au^{198} treatment, for a total of 38 treatments. There were 3 men and 32 women with an average age of 55 years, the youngest 29 and the oldest 75 years old. The type of tumor varied, but the majority were some type of adenocarcinoma. Two-thirds of the adenocarcinomas were primary in the ovary. The patients were divided into 3 groups. Group 1 is composed of patients with no evidence of reaccumulation of ascites at the time of follow-up or death. There were nine patients in this group, five of whom are still living after from 2.5 to 17 months. Group 2 consists of patients who had a remission of ascites for at least six weeks. There were seven patients in this group, four of whom are still living after from two to six months. Group 3 consists of those patients in whom there was no remission or only transient remission of ascites. There were 19 patients in this group. Nine of these patients expired within six weeks of treatment and only two are still living, for five and nine months respectively.

Factors that might explain the differences in the results are reviewed, with the following conclusions: 1. The type of tumor was of some importance, since none of the patients with sarcomas had remissions. 2. That the smaller metastasis was associated with better results was only indicated, not proved. 3. Treatment prior to Au^{198} therapy, treatment after Au^{198} therapy, or combination of the two, whether surgery, radiation, or both, was of little significance in the remission of ascites. 4. The general condition of the patient was important, since one-half of the patients experiencing no remission died soon after treatment. One-half of the patients with pain obtained relief. Complications solely attributable to Au^{198} were uncommon and minor. The authors make a plea for the earlier use of Au^{198}, suggesting that it should be used prophylactically.

A Clinicopathologic Study of the Epiploic Appendages. T. E. Lynn and J. M. Waugh. Surg. Gynec. & Obst. 103:423-433 (Oct.) 1956 [Chicago].

This inquiry into the conditions produced by disease of the epiploic appendages is based on literature reports and on a detailed review of the clinical, surgical, and pathological data in 17 patients observed at the Mayo Clinic from 1940 to 1953. The available literature revealed reports of 156 cases of symptomatic pathological changes of the epiploic appendages prompting surgical intervention. Inflammation (appendagitis) was present in 109 of these cases, intestinal obstruction had been produced by the appendage in 13, and in 34 the appendages were intrahernial. There was primary intra-abdominal appendageal disease in 12 of the 17 patients treated at the Mayo Clinic and in two of these the presenting picture was that of intestinal obstruction. Intrahernial epiploic appendagitis occurred once. In the remaining four patients, other disease processes caused the major symptoms or incited the pathological changes in the appendages. During the same period 129 instances of diseased epiploic appendages without symptoms were found; the majority of these appendages had become detached and were found as intraperitoneal loose bodies.

Pathological changes in epiploic appendages may mimic many acute abdominal inflammatory syndromes; they may form an intra-abdominal mass or produce mechanical intestinal obstruction. They may also be a source of pain in a hernia or may be the sole occupant of an incarcerated hernia. Detached epiploic appendages are the most frequent cause of intraperitoneal loose bodies. These may become secondarily attached elsewhere in the abdomen and be confused with a neoplastic process. Infarction of epiploic tags with superimposed epiploic appendagitis has usually been confused clinically with acute vermiform appendicitis. A preoperative distinction can only be tentative. Should laparotomy fail to disclose the usual sources of acute abdominal pain, epiploic appendagitis deserves consideration. An inflamed epiploic appendage may occasionally produce chronic or recurrent symptoms. The treatment is surgical excision of the diseased appendage. Rarely, a diverticulum of the colon will be encountered within the appendage.

Problem of Intrahepatic Cholangitis Accompanying Cholelithiasis. T. Burckhart. Chirurg 27:408-412 (Sept.) 1956 (In German) [Berlin, Germany].

Eighty-six women and 26 men, 68 of whom were between the ages of 41 and 60 years, underwent cholecystectomy at the surgical clinic of the University of Mainz, Germany, because of a definite clinical suggestion of lithiasis. A preoperative diagnosis of cholangitis had not been made in any of the 112 patients. Biliary calculi were present in the gallbladder in 102 patients and in the common bile duct in 10. Chronic cholecystitis was observed in 93 patients, and only 5 were without abnormal changes in the wall of the gallbladder. A biopsy specimen was obtained from the liver in all patients in the course of the cholecystectomy. Intrahepatic cholangitis was found in 37 patients; other changes in the liver, including pronounced lymphocyte infiltration of Glisson's capsule, increased interstitial connective tissue, diffuse or central fatty degeneration, biliary cirrhosis, and brown atrophy, were present in 36 patients. Fifty-one patients had a history of icterus or were jaundiced at the time of the operation. Nine of the 11 patients between the ages of 61 and 76 years had abnormal changes in the liver, but none of the 33 patients between the ages of 17 and 40 years had such changes. The incidence of cholangitis increases with advancing age. The duration of the cholelithiasis was less than one year in 49 patients, 35 of whom had cholangitis. One-half of the patients with cholangitis also had icterus.

These findings suggest that the presence of a clinically more or less silent intrahepatic cholangitis must be considered as an accompanying disease in patients with apparently uncomplicated cholelithiasis and cholecystitis. Appropriate preoperative treatment should be instituted. Removal of a small biopsy specimen, which in the author's patients was performed without any damage or complication, is justified. The incidence of residual or postoperative complaints after cholecystectomy will thus be reduced and severe early and late complications prevented.

Outcome of Surgery for Ulcerative Colitis. B. N. Brooke. Lancet 2:532-536 (Sept. 15) 1956 [London, England].

What is the expectation of life of patients who have had total colectomy for ulcerative colitis? To find an answer to this question Brooke reviewed the records of the 131 patients with ulcerative colitis who had been operated on by him. In five patients only emergency or diagnostic laparotomy was undertaken; 126 underwent elective surgery (117 excision and permanent ileostomy and 9 resection and anastomosis). The group included 84 females and 47 males. The youngest patient operated on was 6 years old, the colitis having started two years earlier. Operation was resorted to when the patient's general condition had continued to deteriorate despite conservative measures; when the patient was otherwise unlikely to return to normal life; for complications, both anorectal and remote, for the acute emergencies of hemorrhage and perforation, for carcinoma; or to remove this potential hazard in late cases.

There were 15 operative and late deaths. This represents a mortality of 12%—about half the mortality of the disease treated conservatively in the precortisone era. The majority of late complications of operation arose in connection with the ileostomy. Eversion suture of the mucosa to the skin is advocated to reduce the incidence of stenosis. Revision of the ileostomy was required in some cases to enable the patient to use an adherent ileostomy bag. A follow-up extending to five years and longer in over a third of the survivors indicates that ileostomy should no longer be dreaded as an impediment to full, normal life; indeed, it restores patients with ulcerative colitis to full work, full weight, and an enjoyment of ordinary pastimes. In about half the patients the diet has to be restricted slightly. Patients regard their ileostomies as satisfactory. Resection and anastomosis with preservation of the anal sphincter (9 cases) has been less satisfactory in this series than excision and permanent ileostomy (117 cases). The disease may recur after sphincter-saving resection, and its complications may then arise for the first time This method is not recommended as a routine, and its indications are limited; it is precluded for rectal hemorrhage and perforation.

Inguinal Hernia in Female Infants and Children. C. T. Kristiansen and W. H. Snyder Jr. West. J. Surg. 64:481-484 (Sept.) 1956 [Portland, Ore.].

Incarcerations in inguinal hernias are frequent in both male and female infants and frequently require emergency surgery. Kristiansen and Snyder of the California Children's Hospital made a study of incarcerations in the female infants who had received treatment at their hospital from January, 1946, through January, 1955. Of a total of 3,142 inguinal hernias, 351 occurred in girls. One hundred four of the 2,791 hernias in boys were incarcerated or strangulated (3.7%), whereas 51 (15%) of the 351 inguinal hernias in girls were incarcerated or strangulated One hundred sixty or 45% of the hernias in female infants occurred in the group aged one year or under, and this age group contained all of the incarcerated hernias in female infants and children. After the first year of life the incidence of hernias is fairly constant for each year, with no incarcerations or strangulations. Ovary only, ovary and tube, or ovary and small intestine were found in the hernial sac of all but 3 of the 51 female infants with incarcerated inguinal hernia. The ovary and tube were swollen with some discoloration in almost every instance, indicating that prolonged delay may result in some permanent damage to the ovary and its follicles. Tissue death was observed in only one of the infants and even here the ovary was not removed The authors believe that the surgeon can rely on the recuperative powers of the ovary. The organ should not be removed, but should be replaced in the abdomen. Infants and children tolerate surgical repair of a hernia very well, and since there is a negligible mortality, surgical treatment should be carried out as soon as a hernia is discovered. In view of the fact also that the incidence of incarceration is highest in the first year of life, the age of the infant should be no deterrent to operative intervention. This is especially true in female infants, as in this study incarceration occurred five times as frequently in the females as in the males

Giant Cell Tumor of Tendon Sheath. F. L. Flack. J. Oklahoma M. A. 49: 339-340 (Sept.) 1956 [Oklahoma City].

The patient was a 48-year-old woman who had had some pain and swelling of her hand for 10 years but who had continued her employment as a maid in a hotel until shortly before admission to the hospital, when she caught her hand in a clothes wringer This forced her to seek help because of greatly increased pain

There was a tumor mass measuring 20 by 15 cm. involving the entire left hand. The fingers seemed to stick out of the mass. There were many ulcerations, some of them 3 to 4 cm. in diameter. The whole mass was hot, red, tender, and foul smelling. An x-ray film of the hand showed erosions of the cortices of the metacarpals and phalanges with dislocations of some of the joints. Two days after admission she was given 500 ml. of whole blood, but a day later her hematocrit was only 16. She received 500 ml. of whole blood daily for the next five days, and on the ninth hospital day, the patient having received 7 million units of penicillin over this period, the arm was amputated just above the elbow. She was ambulant the next day and was discharged from the hospital on the 12th postoperative day with all of the incisions well healed.

The tumor on microscopic examination proved to be a giant-cell tumor of the tendon sheath. In some sections there were multiple nodules with many foam cells. In others there were nodules composed of giant cells. All through this nodular tumor were acute and chronic inflammatory cellular elements. The foam cells seem to be of special significance, since they are rarely seen in malignant tumors thought to arise from periarticular structures but are a characteristic feature of the benign lesions arising in the same structures. A giant-cell tumor of a tendon sheath reaching a size like that of the tumor described is a very rare finding.

Pathological Fractures: Treatment by Internal Fixation and Irradiation. M. B. Devas, J. W. Dickson and A. M. Jelliffe. Lancet 2:484-487 (Sept. 8) 1956 [London, England].

The results of internal fixation in a series of 18 pathological fractures are described. The operation should be done early, since any delay will increase the difficulty of resetting the displaced fragments. Postoperative swelling is the rule, but pain is not severe and can be controlled by analgesics. The method of internal fixation will vary with the site of the fracture. In the present series, seven malignant and one nonmalignant pathological fracture of the shaft of the femur have been stabilized with a Küntscher nail. Six fractures due to metastases and one due to a nonmalignant lesion of the femoral neck and intertrochanteric region have been stabilized with a Smith-Petersen pin or with a nail and plate. Three pathological fractures of the shaft of the humerus due to metastasis have been treated by the insertion of a Rush pin.

The techniques for the internal fixation of pathological fractures are identical with those for the internal fixation of nonpathological fractures, and the same attention must be paid to gentle handling of the tissues, accurate placing of the chosen device, and absolute asepsis. An antibiotic cover is advisable if there is any doubt as to the complete sterility of the procedure. Closed reduction of the fracture is the safest method, but open reduction may be needed because of malignant infiltration at the fracture site. The results of internal fixation in this small series have been satisfactory. All patients experienced considerable or complete relief of pain, and some patients with widespread malignant disease were able to resume an active life. Postoperative pain was easily controlled, and no patient died as a result of the procedure. The authors believe that all pathological fractures of the long bones should be considered for operation. Prophylactic internal fixation is indicated where there is a real risk of fracture.

NEUROLOGY & PSYCHIATRY

Penicillin Treatment of Asymptomatic Central Nervous System Syphilis: I. Probability of Progression to Symptomatic Neurosyphilis. R. D. Hahn, J. C. Cutler, A. C. Curtis and others. A. M. A. Arch. Dermat. 74:355-366 (Oct.) 1956 [Chicago].

Of a total of 765 patients with asymptomatic syphilis of the central nervous system who were treated with penicillin at eight different hospitals, 34 (4.4%) were given less than 2,400,000 units as the total dose of the antibiotic, 163 (21.3%) were given total doses of penicillin varying between 2,400,000 and 4,799,999 units, 258 (33.7%) were given total doses varying from 4,800,000 to 8,999,999 units, 306 (40%) were given 9 million units or more, and in 4 (0.5%) the amount of drug given was unknown. Two hundred sixty-four patients had not received previous treatment, and whatever previous treatment the other 501 patients had been given was inadequate to produce a cure. The 765 patients were followed up after the penicillin treatment for periods ranging up to six or seven years. The maximum cumulative probability of clinical progression from asymptomatic to symptomatic neurosyphilis was calculated in these patients as 0.55% at the first year, 1.69% at the third year, 2.02% at the fifth year, and 3.31% at the seventh year after the treatment for syphilis. Only 12 of 765 treated patients were recorded as having shown progression of asymptomatic neurosyphilis at the last observation period. Of these patients, only one was unequivocally a treatment failure; this patient responded satisfactorily to retreatment with a larger dose of penicillin. In the other patients there was no clear-cut evidence that the so-called progression did in fact represent progress of the disease process.

In this group, progression could not be related to any of the factors, such as age, race, sex, previous treatment, and retreatment status, considered in the analysis, except in a single patient in whom lack of cooperation precluded treatment when spinal fluid examination clearly indicated a relapse requiring retreatment. Progression, with but one exception, consisted of what can be considered minor neurological or psychiatric changes, and none of the patients was incapacitated by the so-called progression. It is probable that what is considered as progression represents manifestation at the level of clinical recognition of pre-existing subclinical neuraxis damage. The authors' observations suggest that asymptomatic syphilis of the central nervous system responds extremely well to treatment with penicillin; within the study period of from six to seven years it appears that penicillin alone is capable of completely curing asymptomatic syphilis of the central nervous system.

Penicillin Treatment of Asymptomatic Central Nervous System Syphilis: II. Results of Therapy as Measured by Laboratory Findings. R. D. Hahn, J. C. Cutler, A. C. Curtis and others. A. M. A. Arch. Dermat. 74:367-377 (Oct.) 1956 [Chicago].

This report deals with the pretreatment and post-treatment status in terms of results of blood and spinal fluid examinations of the 765 patients with asymptomatic syphilis of the central nervous system who were treated with penicillin and were evaluated in the preceding paper with regard to the probability of progression to symptomatic syphilis. Changes in results of laboratory tests after treatment with penicillin were related to the test status of the given patient in a given clinic at the time of the study treatment with penicillin. Test results were considered to be essentially unchanged, less positive, or more positive. In this way changes in laboratory findings from the eight hospitals in which the patients were treated were analyzed as in a single group of patients. The range of cell count in the cerebrospinal fluid of from 5 to 10 and total protein of from 40 to 50 mg. per 100 cc. was to be considered a borderline zone and was probably within the limits of normality. After successful treatment with penicillin, abnormal cell counts disappeared almost completely within four years; total protein values changed more slowly and did not show the same degree of reversion to what were considered normal limits within that period.

As measured by the fall in cell count, which is the most sensitive index, no clear-cut relationship between success or failure of treatment and size of penicillin dosage could be demonstrated. At most, from cell count studies, it would seem that 9% of the patients might be expected to show a need for retreatment at the end of one year's observation, without regard to the original penicillin dose used. This probably represents a composite group of patients who are failures and patients slow to respond.

It appears that persistently abnormal spinal fluid total protein levels are not, in themselves, indicative of poor prognosis. Significant differences in total protein response were observed in relation to sex and race. The total protein outcome was less favorable in white persons than in Negroes and in men than in women. Spinal fluid tests for syphilis showed a gradual decrease in positivity with the passage of time after treatment; this was more pronounced in the group receiving only a single course of penicillin. Improvement in the spinal fluid test for syphilis was more rapid in the younger patients, in those with disease of shorter duration, and in those with abnormal cell count. A minimum of 28% of the patients with asymptomatic neurosyphilis had a blood serologic titer of 2 units or less. Thus, a weak serologic reaction cannot be considered as indicating absence of spinal fluid involvement. After penicillin treatment of asymptomatic syphilis of the central nervous system there was a gradual trend toward seroreversal, with some patients having more strongly postive results from the serologic test or having positive results after previous negativity. There seemed to be no relationship between serologic negativity and degree of spinal fluid positivity at the onset of the study treatment with penicillin. Changes in the blood serologic test for syphilis after penicillin treatment did not reflect, with any degree of accuracy, changes in the spinal fluid test for syphilis.

Asymptomatic syphilis of the central nervous system responded extremely well to treatment with penicillin. Retreatment on the basis of persistent positive laboratory findings alone is not recommended unless the cell count increases significantly after treatment, remains unchanged at an elevated level for six months after treatment, or increases significantly after approaching normalcy or near-normalcy after treatment.

GYNECOLOGY & OBSTETRICS

Variables in the Diagnosis and Management of Vulvar Carcinoma as Observed by the Philadelphia Committee for the Study of Pelvic Cancer. G. A. Hahn. Am. J. Obst. & Gynec. 72: 756-770 (Oct.) 1956 [St. Louis].

The 131 women with vulvar carcinoma reviewed were treated in 20 different Philadelphia hospitals. The patients were almost equally divided between parous and nulliparous women. Ninety-nine of the women had ceased having menstrual periods, the menopause having been artificial in 11 of them. The most common symptoms causing the patient to seek medical advice were, in the order of their frequency, pruritus, a lump, bleeding, dysuria, pain, ulcer, and discharge. Diabetes mellitus existed in eight of the patients, and six had primary carcinoma elsewhere: two in the breast, one in the buttock, and three in the genital organs (endometrium, ovary, and cervix). The breast and cervical cancers had been diagnosed before, and the carcinomas of the buttock, ovary, and endometrium were discovered at the time the vulvar lesion was being studied.

Delay on the part of the patient alone was a contributing factor in the failure to obtain adequate treatment in 45 instances. In 42 additional patients, physicians or institutions or both had caused further delay, that is, "patient delay" was a factor in 87 (66.41%) of the women. The average delay in seeking a physician's advice was 2.35 years and the longest delay was 12 years. Hope that the difficulties would disappear with time, fear of cancer or that some surgical procedure might be necessary, being too busy, absence of pain, or being too old for any type of surgery were reasons given for not consulting a physician. Only once was finances given as the reason for not asking for a physician's help.

There were 24 women (18.31%) in whom physicians were considered to be wholly to blame for delaying the diagnosis of vulvar malignancy. Three times an institution was considered to be at fault, and in five cases an institution was considered to have contributed to delay. More than one physician was responsible for delay in 12 instances. One patient had visited five physicians before an adequate diagnosis was made. One patient had been hospitalized in two different institutions for orthopedic treatment and had also been under the care of a private physician. The final step in her diagnosis was made by a registered nurse who noted the vulvar growth during her care of the hospitalized patient. In most cases failure to examine the patient was the cause for the delay in making a proper diagnosis. Improper diagnosis was the next most common cause of physician delay. Sixteen different types of treatment, or treatment combinations, were employed in the 127 patients who were treated. Radical vulvectomy with node dissection was most frequently used, then radical vulvectomy alone, and finally x-ray therapy. Fifty-seven patients observed five or more years had a survival rate of 47.37%. The patients who had been treated by radical vulvectomy and bilateral groin dissection had a five-year survival rate of 78.94%. The author believes that the most important factor bringing about a favorable five-year survival rate is the type of therapy rather than the delay involved.

Value and Risk of Pertubal Insufflation. P. Lange. Acta Obst. et gynec. scandinav. 35: 354-365 (No. 3) 1956 (In English) [Stockholm, Sweden].

Two hundred ninety-one women were subjected to 342 kymographic uterotubal insufflations at the fertility department of the Municipal Hospital of Copenhagen, Denmark, between Jan. 31, 1951, and Dec. 31, 1952. Uterotubal insufflation revealed tubal nonpatency in 110 of the 291 patients. Hysterosalpingography was performed after several weeks or months in 83 of the 110 patients. Tubal nonpatency was confirmed by hysterosalpingography in 46 of the 83 patients. Hysterosalpingography showed a normal tubal picture in 23 patients, i.e., there was definite disagreement between the results of tubal insufflation and hysterosalpingography. Hysterosalpingography showed definite abnormal changes in the remaining 14 patients, but there was evidence of peritoneal spill suggesting a certain degree of patency. "Relative" disagreement between the results of tubal insufflation and hysterosalpingography was suggested in these patients. Thus complete agreement between the results of the two methods was found in 55.4% of the patients, definite disagreement in 27.7%, and relative disagreement in 16.9%.

Tubal patency was revealed by the first or subsequent enterotubal insufflation in 181 patients. One hundred eleven of these patients presented a normal kymographic curve; hysterosalpingography was performed in 38 of these 111 patients, and the results were normal in 30. The remaining 70 patients had an abnormal kymographic curve; hysterosalpingography was performed in 33 of these and revealed unquestionable nonpatency in 6 and various forms of anatomic abnormality in 27. The incidence of complications of uterotubal insufflation was surprisingly high with definite pelvic inflammations occurring in 11 patients, i.e., in 3% of the 342 insufflations. No death resulted from uterotubal insufflation, and only two of the 11 patients required admission to hospital, the other 9 being treated as outpatients. None of them required surgical treatment.

The therapeutic effect of uterotubal insufflation was small in that 22 of the 291 patients conceived and only 4 of these fulfilled all the criteria relating the conception to the uterotubal insufflation. The author's observations suggest that a normal kymographic tracing gives considerable certainty of tubal patency. Yet in about 5% of the patients with a normal kymographic curve hysterosalpingography revealed nonpatency. When nonpatency is ascertained by uterotubal insufflation, the examination should be repeated or hysterosalpingography performed.

A Consideration of the Problems of Radiosensitivity in Cancer of the Cervix. S. B. Gusberg. Am. J. Obst. & Gynec. 72: 804-819 (Oct.) 1956 [St. Louis].

Gusberg outlines the three principal methods for radiosensitivity testing of cervical cancer that have been used in recent years to supplement clinical analysis: histological and cytochemical methods have been used to measure the tumor response, and cytological methods have been used to measure the host response. The histological changes have been codified by Glucksmann, who claims that tumors of high differentiation are more radiocurable than those that are anaplastic. Radiosensitivity and radiocurability may not be identical concepts. The second type of investigation is cytological and concerned with host response. The thesis was developed that the radiation response of normal vaginal cells was more important than the response of tumor cells. Recent work is concerned with material obtained before treatment and with sensitization response. It is believed that, if a patient with a cervical cancer has in her vaginal smear 10% or more of benign vaginal cells with a certain quality, she will respond favorably to radiation, whereas if she has less than 10% she will respond poorly to radiation but will have an excellent result if treated surgically. Sensitization response supposedly measures an immune response by the host.

The third type of radiosensitivity investigation is that current in the author's own laboratory. It rests on the thesis that cancer cells dying under radiation will have an alteration in their nucleic acid pattern. Cytochemists have demonstrated that there are two general types of tumor cells, so-called A cells, which are viable and aggressive and have a heavy chromatin pattern (an important site of desoxyribonucleic acid [DNA]) and relatively obscure nucleoli; and B cells, which are relatively inactive, devitalized, perhaps prenecrotic tumor cells whose chromatin pattern is becoming more obscure and therefore have a relatively lowered nuclear content of DNA but whose nucleoli are very prominent, and thus have a relatively higher ribonucleic acid (RNA) configuration in their nuclei. Studies were begun on the basis of the thesis that the growing edge of a cervical cancer prior to radiation should be rich in A cells, and that this zone might show a conversion to a predominance of B cells under radiation if it were responding properly by healing. Four quadrant biopsies were obtained from the growing active zone of the tumor before, and at weekly intervals during, radiation. It was found that healing of cervical cancer in the human can be predicted with some uniformity from the observation of nuclear changes occurring within three weeks after the beginning of radiation in the growing, vital zone of the tumor. The observed changes include: (1) enlargement of the cell and its nucleus; (2) a relative diminution in DNA evidenced by a sort of dilution of the chromatin masses; and (3) a relative increase in DNA as evidenced by an increase in nucleolar size and number. It has been possible to predict tumor healing if there is a shift away from a predominance of an A cell, or active phase, in the growing zone, toward a B cell, or regressive phase. This change implies an alteration in the DNA/RNA ratio with a relative shift toward RNA predominance. The methods as yet are not precise, and these changes are relative: the RNA seems to increase at about the same rate as does the general cell and nuclear volume; the DNA, on the other hand, probably changes very little and therefore shows a relative decrease in concentration. This suggests a specific effect of irradiation on the synthesis of DNA. The author hopes that studies of nucleoprotein patterns will make it possible to predict tumor-cell death in a uniform fashion before conventional histological or clinical methods can detect it. Such cytochemical prognostication could indicate continuation of radiation for those with good response, supplementary lymph node dissection for those with fair response, and discontinuation of radiation in favor of radical hysterectomy for those with poor response.

Subarachnoid Hemorrhage and Pregnancy. D. E. Cannell and E. H. Botterell. Am. J. Obst. & Gynec. 72: 844-855 (Oct.) 1956 [St. Louis].

The authors report 16 women in whom subarachnoid hemorrhage occurred during pregnancy and who were admitted to the obstetric and neurosurgical services of the Toronto General Hospital from Jan. 1, 1950, to Dec. 31, 1955. In four patients subarachnoid hemorrhage occurred with other complications of pregnancy; three of them died. Of the two patients with preeclampsia, one died after cesarean section and the other recovered. The third patient died as a result of thrombosis of the superior sagittal sinus 32 days after an apparently normal pregnancy and delivery. The fourth patient died of subarachnoid hemorrhage from a mycotic aneurysm of the basilar artery following subacute bacterial endocarditis and septicemia after a septic abortion. The remaining 12 patients experienced subarachnoid hemorrhage in otherwise normal pregnancies. Twenty episodes or recurrences of subarachnoid hemorrhage occurred in these 12 patients. Thirteen were primary, and 7 were recurrences shortly after the initial hemorrhage. One patient had subarachnoid hemorrhage in two different pregnancies. Of 13 major primary subarachnoid hemorrhages. seven occurred in the first 20 weeks of pregnancy, four in the latter 20 weeks, and two in the puerperium. None occurred during labor, though the effects of labor as a precipitating factor cannot be discounted in the two that occurred early in the postpartum period. Six of the subarachnoid hemorrhages arose from intracranial aneurysms, three from arteriovenous malformations, and in three the source of bleeding was undetermined. Subsequent angiograms or autopsies show that aneurysms are the cause of a significant number of the subarachnoid hemorrhages said to be of "undetermined origin."

Regarding the diagnosis the authors say that severe headache, often occipital in distribution, nuchal rigidity, nausea and vomiting, loss of consciousness, hemiplegia, and involvement of cranial nerves occurred in this order of frequency. Auscultation of the skull, and particularly the eyeballs, may demonstrate a bruit, diagnostic of arteriovenous malformation. The clinical diagnosis was confirmed by the withdrawal of grossly bloody spinal fluid under pressure. Clinical neurological examination, alone, frequently fails to localize the site of the bleeding. Cerebral angiography is an indispensable step in the diagnosis. Prompt surgical treatment is indicated in pregnant patients in whom subarachnoid hemorrhage occurs as the result of a ruptured berry aneurysm or arteriovenous malformation. The obstetric management of such patients should be based upon sound obstetric principles, cesarean section being employed on indication rather than election.

ACTH and Hyperemesis Gravidarum. E. Ferrario. Minerva ginec. 8: 586-590 (July 31) 1956 (In Italian) [Turin, Italy].

The author studied the effect of corticotropin on the urinary excretion of corticoids and 17-ketosteroids in normal pregnant women and pregnant women with hyperemesis. Four patients affected with severe forms of hyperemesis were given corticotropin. Previous treatments had had no effect on these patients. The results obtained with corticotropin were very good. They seem to prove that adrenal hypofunction of adrenocortical and hypophysial origin is involved in the hyperemesis gravidarum syndrome. The dosage and administration of the hormone cannot be standardized. In general, when the administration of ACTH is stopped the symptoms reappear and readministration of ACTH is required. The authors had no side-effects with the product that they used. If the dosage is not high, the danger to the fetus is limited. Undesirable effects of the drug are dependent on the species of the animal, the dosage, and the stage of pregnancy in which corticotropin treatment is started. A very low dosage does not involve any risk. ACTH does not seem to pass the placental barrier. The possible damage to the adrenal glands of the fetus seems to be caused by the transplacental passage of excessive corticoids produced by the mother. Hyperemesis gravidarum runs its course in three well-differentiated stages: a psychogenic stage, an intermediate stage, and a stage characterized by a true gravidic toxicosis brought about by changes in metabolism caused by liver damage. ACTH would be of no help in the third stage.

PEDIATRICS

Electrolyte Considerations in Exchange Transfusions for Erythroblastosis Fetalis. R. P. Bolande, H. S. Traisman and H. F. Philipsborn Jr. J. Pediat. 49:401-406 (Oct.) 1956 [St. Louis].

The serum electrolytes were studied in 23 erythroblastotic infants before and after 26 exchange transfusions. Refrigerated blood used to replace the circulating blood of erythroblastotic infants is in many instances hyperkalemic and commonly hypocalcemic (citration effect). Under such circumstances striking alterations in the serum electrolytes of the transfused infants must be anticipated. Particular attention was paid to potassium. Many of the infants received donor blood that was markedly hyperkalemic. The majority of infants tolerated an abnormal load of infused potassium without untoward physiological effects or significant change in their serum potassium concentrations. In some instances, rapid infusion of hyperkalemic donor blood appeared to be related to cardiac arrest, death, or both. Critical values could not be definitely established from the limited data at hand. Since it is known that the potassium concentration of donor blood is progressively increased during cold storage, the safest procedures would be to use fresh, warm donor blood at a tolerable rate.

Treatment of Erythroblastosis Fetalis with Special Reference to Sensitization to Rh-Hr Factors Other than Rh_0. A. S. Wiener, I. B. Wexler and G. J. Brancato. J. Pediat. 49:381-393 (Oct.) 1956 [St. Louis].

A number of modifications in the exchange transfusion technique have been introduced by Wiener and associates. To date, 166 babies with erythroblastosis fetalis caused by Rh_0 sensitization have been treated by their latest modification of exchange transfusion by the radial artery-saphenous vein technique. In this latest modification, partially concentrated blood (hematocrit 0.5), preferably not more than three days old, is used. This is prepared by removing part of the citrated plasma after sedimentation has occurred. Depending on the severity of the disease and the size of the baby, from 450 to 900 ml. of such concentrated blood is used for the transfusion. In severe cases the exchange transfusion is repeated, but in no instance are more than two exchange transfusions deemed necessary. Among the 166 babies treated this way, only five died or had neurological sequelae, a crude mortality rate of only 3 ± 0.9%. On the other hand, among babies treated by earlier modifications, by only simple transfusion, or receiving no treatment at all, the mortality rate ranged from 17 to 21%. The difference in results is even more striking when the severity of the disease is taken into account. Thus, among severely affected babies who received no treatment the mortality rate was 65.5 ± 10.6%; among those receiving simple transfusion therapy the mortality rate was 42.1 ± 7.8%; among those treated by previous methods of exchange transfusion the mortality rate was 19.8 ± 2.6%; while among those treated by the latest modification of exchange transfusion, the mortality rate was only 3.8 ± 1%.

Erythroblastosis fetalis caused by sensitization to Rh-Hr factors other than Rh_0 poses an important problem, since the routine antenatal screening test for Rh_0 sensitization does not take them into account. Such cases are rare, but they are just as serious as instances of Rh_0 sensitization. Thus, among nine cases of erythroblastosis fetalis caused by hr′ sensitization, one baby died before treatment could be instituted. Of the remainder, four were treated by exchange transfusion and recovered, while among the four treated by simple transfusion one died and one of the three who survived had severe neurological sequelae. A simple screening test for Rh_0 antibodies consists in testing the patient's serum against ficin-treated cells of types Rh_1Rh_1, Rh_2, and rh respectively. This test should be carried out on all women in labor admitted to the obstetric service and on patients admitted to the surgical or other services who might require blood transfusion. Case histories are presented that illustrate the value of this screening test. In patients with hr′ sensitization the antibodies, even when present in high titer, may react only in tests against enzyme-treated cells and may fail to react in the conglutination and antiglobulin tests. This accounts for puzzling, severe cases of erythroblastosis fetalis in which the direct antiglobulin test for coating of the baby's red blood cells by Rh-Hr antibodies is negative. Certain antibodies, such as anti-F and anti-J, are not detected by the enzyme test, so that the screening test against ficin-treated cells should supplement and not replace the other tests for isosensitization.

Causes of Mongolism. J. Øster. Dan. med. bull. 3:158-164 (Aug.) 1956 (In English) [Copenhagen, Denmark].

An average incidence of mongolism of 1 mongol to approximately every 600 live births, or 0.17%, is reported. In Øster's studies of the cases from the lying-in departments of the Rigshospital from 1923 to 1948, as well as in previously published etiological studies in the literature, the only constant finding has been the older age of the mothers of mongols. No evidence has been found to support the view that mongolism might be hereditary. There is no indication for eugenic precautions in the case of women who have had one mongol child, for the risk of their having another mongol child is not significantly greater than that risk for other women of the same age group. It seems clear that various exogenous maternal factors play a part in the occurrence of mongolism, primarily the more advanced age of the mothers and the depressed reproductive faculty in these women. There is room for intensive continued research on the etiology of mongolism.

Toxoplasmosis as Cause of Mongolism. H. O. Kleine. Ztschr. Geburtsh. u. Gynäk. 147:13-27 (No. 1) 1956 (In German) [Stuttgart, Germany].

Kleine demonstrates on the basis of three cases that mongolism is a special form of connatal toxoplasmosis or at least that it can be caused by toxoplasmosis, because he has observed other cases of mongolism in which the mother had a virus infection during the first three months of pregnancy or cases in which rhesus factor incompatibility played a part. He emphasizes the role of toxoplasmosis and regards it as the most frequent cause. He mentions the following factors as evidence that a toxoplasmogenic embryopathy played a part in the three cases reviewed: 1. The mothers gave strongly positive Sabin-Feldman tests and had roentgenologically demonstrable foci of cerebral calcification as well as pigmentations in the eyegrounds. 2. The infants had nystagmus, strabismus, and encephalitis, and one of the mongoloids had an auricular attachment as an accompanying malformation. The fact that "accompanying defects" are the same in toxoplasmosis and mongolism is further evidence of a causal relation between these two diseases, and such defects aid in establishing the period in intrauterine development during which toxoplasmosis produces the characteristics of mongolism. The damage to the embryo during the "organogenetic" period and the concepts of "embryopathy" versus "fetopathy" are discussed. The first three months of gestation are the period of organogenesis, and it is important that the head and brain develop ahead of the other organs. Intrauterine damage is the more severe, the earlier it develops during the period of gestation. The simultaneous appearance of apparently unconnected defects, for instance the simultaneous occurrence of feeblemindedness and syndactylism or the combination of a defect in the cardiac septum and the absence of the middle phalanx of the fifth finger in mongolism can be explained by damage to centers of organization during the early embryonal period. According to the author's theory, mongolism is an exogenic disturbance in development elicited by a diaplacental infection with toxoplasmosis of an embryo still in the phase of organogenesis, that is, during the first three months of gestation.

The fact that the origin is exogenic and not hereditary is highly important, because it makes prophylaxis possible. Expectant mothers or those likely to conceive should avoid contact with foods or articles that have been contaminated by mice or rats. They should avoid all contact with dogs, cats, rabbits, chickens, ducks, pigeons, sheep, and cows, because these animals are the chief hosts of Toxoplasma. In these animals toxoplasma usually produces intestinal ulcerations, but it may also cause bronchopneumonia and meningitis. This form of prophylaxis is the more important because the therapeutic outlook for mongolism is hopeless.

Malignant Diphtheria. M. Rizzardini and O. Undurraga. Rev. chilena pediat. 27:242-236 (June) 1956 (In Spanish) [Santiago, Chile].

Nineteen children of either sex with malignant diphtheria were observed in a pediatric hospital department for infectious diseases between the years 1946 and 1954. Most of the patients were between the ages of 6 and 12 years. They were hospitalized on the second or third day of the disease. They were acutely ill, with symptoms of acute toxemia, extensive necrotic or hemorrhagic pseudomembranes, purpura, great tumefaction of the neck, and renal and cardiovascular complications. The treatment consisted of the administration of diphtheria antitoxin, in an average total dose of 80,000 units, and of antibiotics. None of the patients survived. Autopsy was performed on 17. The diagnosis of diphtheria was confirmed. In 50% of the cases the membranes invaded the buccopharyngeal cavity, the larynx, the trachea, and, in some cases, the branches of the bronchi. The heart and kidneys were the structures most constantly damaged. Malignant diphtheria can be differentiated from the acute forms of diphtheria. The acute toxemia causes the patient to be greatly excited at certain moments and stuporous at others. The disease, which does not respond to any treatment, such as early administration of large or repeated doses of diphtheria antitoxin, alone or with antibiotics, follows a rapid course, with a mortality of 100%.

A Clinical and Biochemical Study of Galactosaemia: A Possible Explanation of the Nature of the Biochemical Lesion. G. M. Komrower, V. Schwarz, A. Holzel and L. Goldberg. Arch. Dis. Childhood 31:254-264 (Aug.) 1956 [London, England].

The authors report two new cases of galactosemia in children born in 1951 and 1953 respectively. The results of clinical and biochemical investigations and the effect of milk or galactose feeding for 8-or-10-day periods are described, with particular reference to blood glucose and galactose levels, galactose excretion, renal function, and blood and plasma phosphorus levels. Reference is made to the work carried out on certain aspects of erythrocyte metabolism in this disease. The causation of the signs and symptoms of the disease is discussed in the light of the findings reported in this communication. The hypothesis is put forward that the varied manifestations of galactosemia may be attributed to localized accumulation of galactose-1-phosphate within the tissues and that the extent to which such accumulation occurs—and consequently the resulting lesion or impairment of function—is determined by the ratio of local concentration of enzymes concerned with the early stage of galactose metabolism. More than 40 cases of galactosemia have been described in the literature. Galactose has always been implicated as the toxic agent, and the development of hepatomegaly, jaundice, cataract, mental retardation, proteinuria, and, more recently, aminoaciduria, have been attributed to the damaging effect of this sugar on each of the organs concerned.

Free Diets in the Treatment of Diabetic Children. C. C. Forsyth and W. W. Payne. Arch. Dis. Childhood 31:245-253 (Aug.) 1956 [London, England].

The clinic for diabetic children at the Hospital for Sick Children, Great Ormond Street, London, was started in 1926. Initially, strictly weighed diets were used with a carbohydrate content of up to 100 gm. daily. It soon became apparent, however, that many of the children were hungry and that they were not growing well. The food intakes were gradually increased until normal in quantity, and in 1936 free diets were tried for the first time. Concentrated carbohydrates, such as table sugar, jam, chocolate, and sweets, are restricted, but unlimited quantities of plain fare are provided. Cooperation is excellent with regard to the regularity of meals, because the importance of avoiding insulin reactions is soon appreciated, and when the diets are analyzed they are remarkably similar from day to day. Although the diet employed is not truly free, there is a real difference between such a simple diet and a strictly weighed diet.

This paper deals only with patients regularly attending the clinic and those who came for examination in response to a letter and were still on a free diet. The duration of diabetes exceeded 15 years in 41 of the 100 patients, and the others had been diabetic for between one and 15 years. Their ages ranged from 3 to 41 years, and the longest period on a free diet was 18 years. The patients were interviewed and examined, particularly for evidence of retinal degeneration and neurological, renal, or vascular disturbances. Except for short periods of loss of balance due usually to intercurrent infections, all patients remained entirely free from thirst, polyuria, or ketosis. Insulin reactions have been mild and hypoglycemic coma has been very rare. Growth has been satisfactory. The incidence and severity of retinitis increased with the duration of diabetes. A rise in the incidence of retinitis was noted only in patients failing to satisfy the standard of control for more than half of their period of diabetes. Because the over-all results of treatment have been as good as those obtained by clinics employing weighed diets and because of the psychological advantages and the better cooperation achieved, the authors believe that the use of a liberal diet will permit the best control in the greatest number of children.

Gastrointestinal Allergy to Cow's Milk in the Neonatal Period. R. B. Tudor. Journal-Lancet 76: 245-246 (Sept.) 1956 [Minneapolis].

Manifestations of gastrointestinal allergy in children are most commonly due to cow's milk. The first allergic symptoms usually occur from birth to 4 months of age. At this time, the intestine may be sensitive when the skin is not. Skin testing is usually inconclusive. The most common symptoms of gastrointestinal allergy due to cow's milk are colic, vomiting, diarrhea, nasal stuffiness, cough, wheezing, and shock. Unless the child is sensitive to the lactalbumin of cow's milk, goat's milk is not a successful substitute because the casein in cow's milk and goat's milk is identical. Soy bean milk, a weak sensitizing protein, is usually the best milk substitute. The author presents histories of seven infants with symptoms of gastrointestinal allergy due to cow's milk. Most of them improved when soy bean milk was substituted for cow's milk. One required a meat base formula, and another had no further difficulty when goat's milk was substituted for cow's milk.

Idiopathic Hypercalcaemia. W. Kidney. J. Irish M. A. 39:64-67 (Sept.) 1956 [Dublin, Ireland].

Idiopathic hypercalcemia occurs in infancy and early childhood and is associated with an increase in serum calcium and blood urea levels. The chief symptoms are inadequate food intake and vomiting, which result in failure to thrive, wasting, constipation, hypotonia, and lethargy. The child is usually small, undernourished, pale or pink, flabby, and quiet or dull. The age is usually over 4 months and under 2 years at the time of onset. The child may be mistaken for a cretin. The facial characteristics are marked epicanthic folds, overhanging upper lip, wide mouth, large lower lip, low-set ears ("elfin" look), and sometimes squint. Depositions of calcium may occur, particularly in the kidneys, giving rise to persistent infection. Idiopathic hypercalcemia must be differentiated from such conditions as pyelitis, renal rickets, pink disease, Albers-Schönberg disease (osteopetrosis), renal acidosis, and Fanconi's nondiabetic glycosuria.

The author describes observations on 13 children with idiopathic hypercalcemia. Children with the mild form may recover in a few months or years, but in those with the severe form physical and mental retardation, stunting, and deposition of calcium in the lungs, muscles, and kidneys may finally lead to death. There is no specific treatment, but elimination of vitamin D may be tried, because the child may have received excessive doses or may be hypersensitive to normal doses. Reduction of calcium intake by the elimination of cow's milk, which contains four times as much calcium as does human milk, may be desirable. Cortisone or one of its modifications usually produces great improvement, but it is too early to decide whether it will prevent the mental retardation so often found in the chronic form of idiopathic hypercalcemia.

UROLOGY

The Resemblance of Hypertrophy of the Prostate to Congenital Polycystic Disease: Reconstruction of Cystic Lesions of Hypertrophied Prostate in Three Cases. R. F. Norris, V. E. Martens and R. W. O'Gara. J. Urol. 76:276-286 (Sept.) 1956 [Baltimore].

The similarity of the lesions of hypertrophy of the prostate and of polycystic disease of the newborn is described, and the lesions in the prostate are illustrated by means of reconstructions from serial sections in three patients. The first prostate was selected for study because it was considered typical of a man in early middle age. The areas of glandular enlargement were localized and not extensive. In the serial sections studied, none of the enlarged glands were seen to be isolated as cysts. The second prostate was selected because it showed a preponderance of glandular hyperplasia and the third because of a preponderance of fibromuscular hyperplasia. Neither gland was unduly enlarged. Greatly hypertrophied prostates were not chosen for study because it was feared that the first changes in structure might be obscured in advanced stages of the disease. As regards polycystic disease of the newborn, evidence has previously been presented by the senior author (R. F. Norris) and his collaborators to show that the embryologic development and differentiation of polycystic organs progresses while the cystic lesions are being formed. As a consequence of the epithelial cystic proliferation, the ducts or epithelial tubules eventually are pinched off as isolated segments or as dilated cysts. This sequence of changes resembles the phenomenon of normal resorption of the provisional organ, the mesonephros. In the latter instance, segmentation of tubules and isolation of glomeruli as cysts normally precede the resorption of these elements as the mesonephros degenerates. Since the first generations of tubules in the metanephros are also thought to be normally provisional, the authors suggest that segmentation and cystic dilatation of the tubules in polycystic disease of the kidney and of other organs represent an extension of this normal process of resorption to a pathological degree. The epithelial lesions of the hypertrophied prostate characterized by cystic dilatation of ducts and acini and by the isolation of blindly-ending cystic complexes resemble the lesions of congenital polycystic disease.

The objection may be raised that polycystic disease of the newborn differs from hypertrophy of the prostate in the short time required for its development. This difference may be more apparent than real if the rapidity of all embryologic development is taken into consideration. So far as the authors know, neither polycystic disease nor hypertrophy of the prostate has been reproduced experimentally in animals. The cause of each disease, therefore, is obscure. Whether there are etiological factors in common is still unknown, but in the case of hypertrophy of the prostate, the belief persists that imbalance of endocrine secretions is the cause of the disease. Endocrine disturbances during pregnancy, however, have not been extensively investigated as a cause of polycystic disease. The conclusion seems warranted that the similarity of the lesions of hypertrophy of the prostate to those of congenital polycystic disease is important not only because lesions of embryologic development can be mimicked in the organs of adults, but also because the two diseases may have etiological factors in common.

Congenital Renal Aplasia with Calcified Cystic Degeneration: Report of Two Cases and Review of the Literature. B. S. Abeshouse. J. Internat. Coll. Surgeons 26:283-296 (Sept.) 1956 [Chicago].

The author has collected 16 cases of extensive calcification of cysts in congenitally aplastic kidneys. He describes two additional cases of this unilateral condition in a 40-year-old woman and a 78-year-old man. Analysis of the literature on congenital renal aplasia with and without cystic degeneration and of the observations made in the two patients with congenital aplastic kidneys containing calcified cysts warrants the following conclusions: 1. There is a definite need for an exact definition of the three important congenital anomalies of renal structure, i. e., agenesis, hypoplasia, and aplasia, to enable the urologist and pathologist to diagnose and classify the cases properly. 2. The distinguishing clinical and pathological features of renal agenesis, hypoplasia, and aplasia permit an accurate differential diagnosis, which may be made with the aid of cystoscopic studies, excretion tests with indigo carmine and phenolsulphonphthalein, and roentgenographic studies, particularly excretory urography and retrograde pyelography.

Renal aplasia is characterized by a total lack of definite renal anatomic form and physiological function in infants and children. In adolescents and adults the aplastic kidney may exhibit marked cystic degeneration, apparently the result of arrested development in the metanephric stage. In one patient total excision of the retroperitoneal mass was carried out. Microscopic sections through the cyst wall showed groups of vestigial tubular structures lined in part by pseudostratified tall cuboidal epithelium. There were also scattered small cysts. The cysts were encased in a dense collagenous fibrous tissue. There were foci of calcium deposition as well as of osseous tissue formation. Renal aplasia associated with cystic degeneration has also been described as multicystic or congenital cystic hypoplasia and not infrequently confused with unilateral polycystic kidney and multiple serous cysts of the kidney. The pathogenic and pathological aspects of calcification, ossification, and cartilage in the walls of the cystic type of aplastic kidney are discussed.

Local Hydrocortisone for Hunner's Ulcer of the Bladder. J. H. Johnston. Brit. M. J. 2:698-699 (Sept. 22) 1956 [London, England].

The patients treated were women aged 63, 68, and 73 years in whom interstitial cystitis with ulceration (Hunner's ulcer) had existed for from two to six years. Treatment by bladder distension with the patient under anesthesia, zinc ionization, and vesical irrigation had formerly been carried out on many occasions. In January, 1956, each was treated by cystoscopic injection of hydrocortisone into the bladder. All have shown marked symptomatic improvement beginning a few days after the injection. The total duration of the remission produced by this therapy is not known, but it is to be expected that, when symptoms recur, further infiltration of the bladder musculature will again be effective. The author learned that Schulte and Reynolds obtained satisfactory results with a similar technique using hydrocortisone and hyaluronidase.

OPHTHALMOLOGY

Report on 104 Cases of Glaucoma Operated upon by Galvano-Cautery Puncture. R. Colley. Brit. J. Ophthal. 40:436-438 (July) 1956 [London, England].

Colley performed the first galvanocautery puncture on July 27, 1950, and since that date all patients with glaucoma of whatever type admitted to his care at the Bath Eye Infirmary for operation have been treated by this procedure. In all, 121 galvanocautery punctures were performed on 104 eyes—100 by the author himself and 21 by an assistant. Fifty-four of the operations were performed in chronic simple glaucoma, 34 in acute or subacute glaucoma, and 33 in secondary glaucoma. Local anesthesia was used in 72 and general anesthesia in 49 operations. The operative technique used was a slight modification of the galvanocautery puncture described by Preziozi in 1924 and in 1950. The results in chronic, simple, acute, and subacute glaucoma appeared to be as successful as those obtained with most other operations. In cases of secondary glaucoma—apart from those due to uveitis—the results were very poor.

Although the number of patients operated upon is insufficient for final conclusions, Colley feels that Preziozi's galvanocautery puncture is worth a more extensive trial. It is very similar to Elliott's trephine operation, but is even easier to perform and takes a shorter time. Other advantages of the galvanocautery puncture are that it can be performed under local anesthesia, especially in old or ill patients, and that the slow escape of the aqueous when the limbus is pierced makes an intraocular hemorrhage very unlikely.

Water-Drinking and Tonography in the Diagnosis of Glaucoma. B. Becker and R. E. Christensen. A. M. A. Arch. Ophth. 56: 321-326 (Sept.) 1956 [Chicago].

Although characteristic field loss and cupping of the optic nerve head establish the diagnosis of glaucoma, therapeutic efforts in the chronic simple variety of this disease depend upon early detection. Methods available for its diagnosis include tonometry, provocative tests, and tonography. The fact that glaucomatous eyes can demonstrate decreased facility of outflow in the absence of elevated intraocular pressure accounts for their earlier recognition by tonography than by tonometry. When tonography was combined with provocative tests, it was noted that some glaucomatous eyes responded with induced impairment of outflow facility in spite of a failure of this procedure to provoke a rise in intraocular pressure. Thus, tonography before and after water-drinking provided a more sensitive method for the detection of glaucoma than did either alone. A comparison is presented of tonometry, water-drinking, and tonography on 175 normal eyes and 188 eyes with chronic simple (open-angle) glaucoma and loss of visual field. The two groups of eyes could best be separated on the basis of data obtained from tonographic tracings one hour after drinking 1 liter of water.

INDUSTRIAL MEDICINE

An Occupational Agent (N-Butyraldoxime) Causing Reaction to Alcohol. W. Lewis and L. Schwartz. M. Ann. District of Columbia. 25:485-490 (Sept.) 1956 [Washington].

An unpleasant reaction after the ingestion of small amounts of alcohol was noted recently in a large printing company. The agent that is absorbed into the body and "sensitizes" the printers is known as the antioxidant N-butyraldoxime. After such "sensitization" the response to alcohol consisted of a reddish, violescent, nonitching, coalescing, macular rash of the face, neck, and upper trunk; congestion of the conjunctiva and nares; congestion of the mucous membranes of the throat, which caused dyspnea without wheezing, and palpitation. The "reaction" to alcohol caused by N-butyraldoxime is similar to but milder than the Antabuse-alcohol reaction. The blood acetaldehyde level, which is elevated by the absorption of N-butyraldoxime, is further markedly elevated shortly after the ingestion of alcohol, and this causes the unusual "reaction." The effects of exposure to N-butyraldoxime largely disappear in 24 hours. Apparently no permanent damage is done to the body by the new agent. A new "cure for alcoholism" may have been found.

THERAPEUTICS

A Class Experiment on Ganglion Block in Human Subjects. W. D. M. Paton and H. Steinberg. Brit. M. J. 2:622-627 (Sept. 15) 1956 [London, England].

The pharmacology class at University College Hospital in London provided an opportunity whereby some knowledge about the action of ganglion-blocking agents could be obtained in a population of healthy young adults, at the same time receiving training in making clinical observations and in rendering these observations quantitative. The students worked in groups of four, with one student as subject and the remaining three as observers dividing the various duties among themselves. A set of observations was made every 20 minutes, *timed* with a stop-clock, in the following order: supine blood pressure and pulse rate; standing blood pressure and pulse rate; skin temperature, body temperature, and room temperature; salivary secretion and sweating rate; ocular accommodation and reaction to light. This sequence was strictly followed, so that the interval between successive particular types of observation was kept constant. Two sets of control observations were made before injection of the drug, the subject having been instructed to take a light lunch, not to drink too much, and to empty his bladder. Immediately after the second set of control observations, 25 mg. of hexamethonium bromide was injected subcutaneously into the deltoid area.

The most common effect was a fall in body temperature (90% incidence) and rise in skin temperature (76%); and then (in descending order of frequency), fall in supine and standing systolic blood pressure, rise in supine and standing pulse rate and reduction in salivary secretion, and reduction in the reaction of the pupil to light and to accommodation (30-40% incidence). Sweating was also reduced. The incidence of ganglionic block over the various autonomic functions tested was different in every one of the 41 subjects for whom complete records were obtained. Variability in the response to a ganglion-blocking agent is as great in normal subjects as in patients. It may be regarded as a result of the varying autonomic constitution of different individuals.

Acute Renal Failure During Pentolinium Therapy. A. B. Carter and R. W. Payne. Lancet 2:537-539 (Sept. 15) 1956 [London, England].

Carter and Payne report the histories of two men, aged 69 and 46, respectively, in whom acute renal failure developed while they were being treated for hypertension with pentolinium tartrate (Ansolysen). The type of renal failure suggested an initial lowered filtration rate associated with prolonged hypotension followed by failure of tubular function. These two cases suggest that the continued use of pentolinium tartrate may be dangerous to elderly patients, although the usual side-effects of postural vertigo, constipation, and dryness of mouth may be absent. The use of pentolinium in the elderly can be justified only as a life-saving measure in cases of left ventricular failure, progressive gross retinal changes, or continuing hypertensive encephalopathy. The patient should be instructed to watch for listlessness, drowsiness, or any diminution in volume of urine and thereupon to stop taking the tablets. Once renal failure is suspected in a patient receiving pentolinium tartrate and the drug has been withdrawn, it is important to restore circulation as quickly as possible by raising the blood pressure. An intramuscular injection of 10 mg. of methedrine sulphate was effective in each case. Care should be used in prescribing larger doses because hypertensive patients remain very susceptible to methedrine even when they are in hypotension. Once the blood pressure has become reasonable, the treatment should be as for anuria from other causes.

Breast Cancer and Heptaldehyde (Preliminary Report). R. N. Lawson, A. L. Saunders and R. D. Cowen. Canad. M. A. J. 75: 486-488 (Sept. 15) 1956 [Toronto, Canada].

The rarity of cancer of the breast in Eskimo women in Canada has led to an investigation of their mode of life. The most striking aspect of their diet is the high proportion of fat, much of which is consumed in a frankly rancid state. Heptaldehyde is one of the chemical factors found in rancid fat. Earlier investigators had observed that when this substance is added to the diet of mice harboring spontaneous carcinomas of the mammary gland, liquefaction and regressive changes of the tumors resulted without apparent injury to the animals. The authors studied the toxicity of heptaldehyde in rats, demonstrating the fact that the lethal dose in 200-gm. rats was between 4 and 5 cc. They have given over 300 doses of 1 cc. each to human patients without any apparent ill-effects. They have used as much as 3 cc. but have confined the maximum quantity to 1 cc. in any single injection site.

Two patients with inoperable metastatic breast cancer were given intragluteal injections of heptaldehyde at intervals of one week. Both patients experienced a painful response in the site of the malignant tumor within five minutes of the intragluteal injection. The areas of the breast surrounding the tumor did not become tender. Tumor growth appeared to be immediately arrested. After eight weeks, treatment was discontinued, as the pain phenomenon in the tumors was cumulative. Tenderness and pain in the tumor nodules increased with repeated doses and persisted for longer periods. Three weeks after cessation of treatment, one patient was given 300 mg. of testosterone. Within 24 hours all the tumor areas visibly increased in size, and she died five days later. The other patient underwent simple mastectomy, and she is now alive and free of gross disease 10 months after treatment. Extending the studies to other patients with breast cancer, the authors found that four-fifths experienced a pain reaction within the tumor within from four to eight minutes after the injection. On several occasions when the drug inadvertently entered the blood stream, as evidenced by a rancid taste in the mouth and pain in the breast tumor, there was a distinct drop in skin temperature over the cancer within 10 minutes of the injection. Since no demonstrable thermal changes were noted after administering heptaldehyde in any case of benign or inflammatory breast disease, it would appear that this phenomenon could be a useful clinical test for breast cancer.

Symptomatology and Pathogenesis of Intoxication with Penicillin Ester. G. Wichmann, E. Koch and F. Heiss. Ztschr. klin. Med. 154:111-125 (No. 2) 1956 (In German) [Berlin, Germany].

Experiments were carried out on guinea pigs and rats given injections of the hydriodide of the diethylaminoethyl ester of penicillin by the intramuscular, intracardiac, and intracerebral routes and into the carotid arteries. Similar experiments had previously been made with sodium penicillin G. Three standard syndromes of intoxication were observed in both guinea pigs and rats after the administration of the penicillin ester: acute generalized tonic-clonic spasms, acute diffuse pulmonary edema with pulmonary hemorrhages, and enterocolitis with a protracted course and terminal collapse. Acute generalized spasms and acute pulmonary edema were produced in the animals by the intramuscular administration of the penicillin ester, but these acute syndromes were not produced when sodium penicillin G was given by this route; they were, however, produced by both penicillin ester and sodium penicillin G when given by the intracerebral route or into the carotid arteries. The severity of the intoxication syndrome that occurred in the animals after the administration of the penicillin ester always depended on the degree of concentration of the penicillin ester in the cerebral tissue. It appears that the penicillin ester passes the blood-brain barrier in the animals and that the penicillinase activity in the cerebral tissue is temporarily inhibited. The results are a breaking-down of ganglion cells, acute spasm syndromes, and pulmonary edema. A review of the literature showed that after the administration of penicillin ester preparations to human beings the incidence of symptoms of intoxication was 130 times higher than after the administration of procaine penicillin preparations.

Jensen and Hallas-Moller and his Danish co-workers reported that the concentration of the penicillin ester in the pulmonary tissue of guinea pigs was three times higher than that in the blood, while the pulmonary tissue concentration of the penicillin G alone, which has an antibiotic effect apart from the ester compound, was not higher than its concentration in the blood. The authors' observations in the course of their experiments in animals and reports in the literature of observations in man establish the fact that the pulmonary affinity for the penicillin ester in animals and in man applies only to the ester itself, while the concentration of the penicillin freed from the ester compound is about the same in the pulmonary tissue and in the blood.

Penicillin ester preparations have been recommended for the treatment of patients with inflammatory cerebral disturbances, pneumococcic and meningococcic meningitis, and inflammatory diseases of the lungs. From the viewpoint of the greatest usefulness and the least damage, penicillin ester preparations are definitely inferior to sodium penicillin G in the treatment of all of these diseases.

ANESTHESIA

Roentgen Therapy and Cyclopropane Sensitivity. P. A. Foster. Anesthesiology 17:735-738 (Sept.-Oct.) 1956 [Philadelphia].

A 39-year-old man received a course of deep roentgen therapy for carcinoma of the floor of the mouth. The irradiation was completed five weeks before an operation was scheduled. There had been no radiation sickness, and the patient had been able to eat, had not lost much weight, and was in good general condition. A two-stage operation was planned in which suitable skin pedicle grafts would first be fashioned for use at the second stage when reconstruction of the lower jaw was to be carried out after resection of part of the mandible. It proved impossible to maintain this patient on cyclopropane because of extreme sensitivity. After a flow of this gas of 200 ml. per minute had been allowed to enter the closed circuit for two or three minutes, respiratory arrest followed that lasted for approximately half an hour. Pulse and blood pressure, however, were relatively unaffected. Eventually, the use of cyclopropane was discontinued, and nitrous oxide with minimal ether, and Demerol intravenously, was substituted. He did not prove unduly sensitive to this combination, tolerating amounts that experience suggested was normal for a person of his age and sex. Recovery was uneventful after the surgery, which took five and one-half hours.

An extreme sensitivity to cyclopropane may be shown by elderly people, especially if their premedication has included a respiratory depressant, but it is not usually seen in younger adults. The selective depression of respiration with poor analgesia in this 39-year-old man is regarded as significant because it has been observed that animals exposed to roentgenization of the whole body show an especially poor tolerance for cyclopropane but not for ether, ethylene, nitrous oxide, or thiopental sodium. Radiation therapy would probably not have such an effect on human beings unless the cerebrospinal axis is in the path of the beam. It is suggested that irradiation around the head may increase the permeability of intracranial vessels, thereby allowing entry to certain drugs (for example, relaxants) that are normally excluded by the blood-brain barrier. Drugs that normally penetrate may do so in greater degree. The peculiar pattern of neuronal radiation damage seen suggests that an excessive vagal tone may increase the hazards of intubation with cyclopropane, that consciousness may be more easily depressed, and that disturbances of temperature regulation may be encountered. Unusual responses to anesthesia following radiation therapy have received little attention in the literature. They may prove important during the treatment of casualties following an atomic explosion.

Control of Postoperative Vomiting with Marezine: A Double Blind Study. D. C. Moore, L. D. Bridenbaugh, V. F. Piccioni and others. Anesthesiology 17:690-695 (Sept.-Oct. 1956 [Philadelphia].

The effectiveness of parenteral injections of Marezine (cyclizine lactate) to control postoperative vomiting was investigated with a method that has been developed as a standard for antiemetic drugs. The cyclizine is injected intramuscularly when the patient is taken to the operating room, again intramuscularly on return from the operating room, and then intramuscularly every four hours for four doses. In this experiment, 1 cc. of solution was injected each time. The cyclizine solution contained 50 mg. of the drug per cubic centimeter. During a double-blind study on 276 patients, who were operated on under various types of anesthesia, it became evident that cyclizine lactate significantly reduced the incidence of postoperative vomiting. This would seem to substantiate previous reports, which had asserted the effectiveness of cyclizine but had not employed the double-blind technique in evaluating the drug.

BOOK REVIEWS

Medical Effects of the Atomic Bomb in Japan. Edited by Ashley W. Oughterson, Clinical Professor of Surgery, Yale University School of Medicine, New Haven, and Shields Warren, Pathologist, New England Deaconess Hospital, Boston. National Nuclear Energy Series. Manhattan Project Technical Section, Division VIII—Volume 8. Cloth. $8. Pp. 477, with illustrations. McGraw-Hill Book Company, Inc., 330 W. 42nd St., New York 36; 95 Farringdon St., London, E.C.4, England, 1956.

This well-illustrated and well-documented book concerning the medical effects of weapons that have altered history and our way of life should be of great interest to physicians throughout the world. The first chapter contains an excellent summary of findings, which are afterward documented in detail in appropriate chapters. The book is fairly comprehensive in that it describes the prelude to the work and the scope of damage and effects on medical care and facilities, presents statistical data on population and casualties, and discusses medical aspects from the viewpoint of the clinical observer, the hematologist, and the pathologist. Six appendixes, dealing with subjects such as organization and personnel, materials and methods, population, and statistical data, afford more specific information concerning the studies reported in the text. The index is weak. The book is literally crowded with facts and material that one may study for hours. Perusal of the summary chapter and selected reading of other portions will rapidly acquaint the medical reader with the general and specific medical problems of nuclear warfare. The colored plates vividly depict the injuries. Some of the photographs are reproduced from early Japanese military reports which illustrate early findings that United States survey personnel did not observe because of their arrival in the areas weeks after the bombings. This is a valuable book for background and reference for physicians concerned with the medical aspects of nuclear warfare and, in addition, for persons engaged in military medicine, which includes those who are concerned or who should be concerned with the medical aspects of civil defense—namely, all physicians.

The Administration of Health Insurance in Canada. By Malcolm G. Taylor. Cloth. $5.65. Pp. 270, with 5 illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Toronto, Canada, Amen House, Warwick Sq., London, E.C.4, England, 1956.

Today about 50% of Canada's population is enrolled in some type of health insurance plan. With attention concentrated primarily on the Blue Cross hospital care plans, the medical care plans sponsored by the provincial medical associations, and the hospital and social assistance medical care programs operated by the government, this study encompasses a total of 24 specific insurance plans. An evaluation of the various plans is based on detailed examination and description of the differing objectives, achievements, and problems of each type of plan. In developing his central theme of the task of administering health insurance, the author discusses extensively such matters as the determination of benefits and premiums and the effects of the individual plans on the physicians, hospitals, and patients involved. The author's personal observation provides the principal basis for a substantial part of the text. The 38 tables and figures that appear in the book and the numerous text tables serve as helpful supplements to the written text. Much of the tabulated material, however, is not fully documented with specific references to exact sources and/or to the author's method in arriving at statistics.

The Canadian Blue Cross plans, modeled after those developed in the United States, operate on the service benefit principle whereby a maximum number of days of hospital care per year plus necessary extras (operating room, drugs, and dressings) are provided. The five Blue Cross plans operative in Canada are coordinated by the Canadian Council of Blue Cross Plans. In addition to their hospital care benefits, three of the plans offer a limited medical and surgical benefits contract of the indemnity type. In 1954 about 3,255,000 people were enrolled in Blue Cross plans for hospital benefits, and 1,027,000 for medical and surgical indemnity benefits. The profession-sponsored medical care plans also provide benefits on a service basis. In contrast to most of the profession-sponsored plans in the United States, many of the Canadian plans offer home and office calls by physicians as benefits. The physicians accept a 10% reduction in fees to cover administrative costs. These plans cover 1,353,000 persons. Government-sponsored hospital care plans have been established in four Canadian provinces in which total enrollment in 1954 was 2,696,000 persons. The Swift Current Medical Care Plan is the only example of a government-sponsored program covering all the residents of a large area (about 50,000 people in southeastern Saskatchewan reside in the region served by the Swift plan). This comprehensive medical care program is supported by taxes levied on all residents and provides payment to physicians on a fee-for-service, contract-schedule basis. Public medical care plans apply only to those groups in the population receiving social assistance of some sort. The number of such beneficiaries in 1953-1954 was 293,792.

One of the most serious problems facing government-sponsored plans concerns enrollment, which must necessarily encompass the entire population. The absence of the promotional function does not counteract the obstacles that obligatory comprehensive and simultaneous registration and tax payment present. In Canada today, all of the 10 provinces exercise some degree of supervision over all of the hospital and medical care programs. While the amount and type of supervision varies from province to province, in the author's opinion, successful administration will soon necessitate a degree of uniformity. Taylor describes the position of the physician in private practice as "anomalous"—on the one hand, he is a confidant and an alleviator of pain, on the other hand, he "is a prime example of the small businessman with fixed and variable costs in operating his practice whose income is the difference between his revenue and expenditures." In the author's thinking, these two functions tend to conflict. He believes that the physician, in asking remuneration for his services, counteracts his beneficial work by inciting worry, fear, and "continuance of the state of ill-health." In respect to this, Taylor quotes Stern who says, "the attitude of the lay public is that the physician is the beneficiary of another's misery." It is on the basis of this premise that the main criticism of the book can be promulgated. While the physician feels entitled to just remuneration, his primary role is that of a professional servant and not that of a tradesman or businessman. To equate the two roles is to misinterpret the function of the private physician, as well as to miscalculate his own conception of his role in society. Although an economic factor does exist in the doctor-patient relationship, it can be contended that this element is subordinate to the quality of care that the physician strives to provide.

Taylor points out that administrative regulations are time-consuming and irritating to the physician, but he also implies that such disadvantages are offset by the advantages of being able to offer whatever treatment the physician believes necessary without concern over the patients' ability to pay. It should be remembered that this advantage is greatly limited by the extent of the patients' insurance coverage. In conclusion, the author points out that governmental controls are the lesser of two evils, the greater being unpredictable and frequently unmanageable medical bills. This view would appear to be an oversimplification of the problem. Aside from the inevitability of the economic factor in medical care (which is an essential factor regardless of whether health insurance is available), the principal problem to be resolved in regard to health insurance would seemingly involve an evaluation of the effect of controls on the quality of medical care. Physicians believe that further controls would be detrimental, indicating that Taylor's "two evils" have been ill-defined. The medical profession believes that any form of contractual practice is unethical to the extent that it results in a deterioration of the quality of the medical services rendered; thus, the effects of increased nonmedical control on the quality of medical care seem to the physician an unreasonably high price to pay for the opportunity to "budget medical care expenditures."

These book reviews have been prepared by competent authorities but do not represent the opinions of any medical or other organization unless specifically so stated.

Techniques and Procedures of Anesthesia. By John Adriani, M.D., Director, Department of Anesthesiology, Charity Hospital, New Orleans. Second edition. Cloth. $8.75. Pp. 568, with 192 illustrations. Charles C Thomas, Publisher, 301-327 E. Lawrence Ave., Springfield, Ill.; Blackwell Scientific Publications, Ltd., 24-25 Broad St., Oxford, England; Ryerson Press, 299 Queen St., W., Toronto, 2B, Canada, 1956.

This second revised edition of a popular textbook follows the purpose of the first edition, namely, to provide an outline for students of anesthesiology. The important points are presented in a concise but comprehensive manner. The text is divided into 10 parts. The first consists, after a few definitions, of tables giving the general properties of anesthetic drugs, and suggestions for selecting procedures of giving anesthetics for operations on the different regions of the body and drugs to be used when the most commonly encountered clinical conditions are met. Much of this material is from the author's book, "Selection of Anesthesia." The recommendations made are presented in outline form, and the justification for them is supported not by discussion but simply with a brief remark. This part also includes discussion of preanesthetic medication, a subject presently undergoing radical changes with the introduction of new drugs and new concepts. The recommendations given here reflect the recent teaching on this subject but not necessarily the latest methods. There is also a discussion of records of anesthesia and their preparation.

The second part is devoted to inhalation anesthesia. It briefly describes the drugs used and particularly the appliances. The use of the latter is covered in some detail with many photographic illustrations. This section covers the use of endotracheal equipment also. The classic signs of anesthesia of Guedel are given, although in present practices they alone are not sufficient to guide the clinician in determining the depth of anesthesia. The third part covers the complications of anesthesia and gives sound recommendations for avoiding and managing them. Basal narcosis with intravenous injections and rectal anesthesia are the subjects of the next two parts, followed by a section on regional anesthesia. Although this section covers one-fifth of the book and is fairly well illustrated, it provides the student with too little information to be of much value. Many of the most recent practices have not been included and some of the recommendations are debatable. For example, the author implies that blocks, excepting skin wheals, are best done with 22-gauge or larger size needles.

Specialized procedures occupy the next part, including pediatric, geriatric, thoracic, and obstetric methods. Little can be done with any of these subjects within the limited space allotted, therefore the text attempts little more than an outline of suggested procedures that are essentially the same as those already described. Recovery rooms are given some space in the final pages of this section. In the last two parts, resuscitation and inhalation therapy are considered. There is an appendix with clinical laboratory values and a good index. A brief bibliography is found at the end of each discussion. The illustrations show various types of equipment and their use. The book is an example of excellent design and printing. The author is to be congratulated on packing into so few pages the vast number of subjects included. Although the outline form will appeal to many, the book will probably be most useful to those beginning the study of this subject and possibly to those anticipating examinations by qualifying boards.

Epilepsy and the Law: A Proposal for Legal Reform in the Light of Medical Progress. By Roscoe L. Barrow, Dean, University of Cincinnati College of Law, Cincinnati, and Howard D. Fabing, M.D., Chairman, Legislation Committee, American League against Epilepsy. Cloth. $5.50. Pp. 177. Paul B. Hoeber, Inc. (medical book department of Harper & Brothers), 49 E. 33rd St., New York 16, 1956.

This book is described on the title page as being "a proposal for legal reform in the light of medical progress," but Dr. Pearce Bailey, in his foreword, recognizes that, for all its scholarship, this book is part of the literature of indignation. If all who read the book are as aware as was Dr. Bailey of the easily discernible use of half-truths and innuendo in seeking to appeal to the reader's emotions, then more good than harm should come from a widespread reading of it. The authors sincerely contend that medical progress in the control of epileptic seizures has outmoded our epilepsy laws. Four principal areas of complaint are covered: marriage license laws, sterilization laws, driver's license laws, and workmen's compensation laws. The best case is made for the first two. From the material presented, there seems to be little doubt that epilepsy is not the same as idiocy and insanity and that there is no eugenic reason for treating them in the same manner. It also appears that epilepsy is not an inherited disease. Society, therefore, will not suffer by permitting epileptics to marry and by eliminating epileptics from the purview of the eugenic sterilization laws. Granting the foregoing and granting that down through the years an unfortunate social stigma has attached to epilepsy, the authors are not able to present quite as good a case for amending the driver's license or workman's compensation laws. A driver who has an epileptic attack while driving 60 mph on a busy highway and an epileptic who drops one end of a heavy box that he is lifting with a fellow employee can cause serious injury to those other than himself. More than mere social stigma is involved. The authors do, however, insist that the privileges that they seek for the epileptic must be limited to the epileptic who is free from seizures and under a physician's care. Like most "literature of indignation," this book will find violent supporters and violent opponents. On the whole, however, it furnishes a valuable addition to the literature on the subject and may help to elevate the status of the epileptic in some degree. The appendix contains examples of the type of laws the authors believe should be enacted, and there is a commendably complete index, bibliography, and citation of legal references.

Management of Emotional Problems in Medical Practice. Edited by Samuel Liebman, M.D., Medical Director, North Shore Health Resort, Winnetka, Ill. Cloth. $5. Pp. 152. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; 2083 Guy St., Montreal, Canada; [British agent—Pitman Medical Publishing Co., Ltd., 39 Parker St., Kingsway, London, W.C.2, England], 1956.

This volume is the second in a series based on lectures given at the North Shore Health Resort, Winnetka, Ill., by nine distinguished physicians. Each lecture presents practical approaches to the management of the emotional problems treated daily by the medical practitioner. Dr. Karl M. Bowman's paper on psychiatric emergencies or what to do before the psychiatrist comes is full of good practical sense and gives special consideration to the violent patient and the suicidal patient, and how to manage problems of drug intoxication, refusal to eat, panic states, and hysterical states. Dr. Francis J. Gerty gives excellent advice on the use and abuse of sedatives and stimulants. Dr. Lewis Robbins considers the management of the anxious patient and takes up the symptoms, psychodynamics, and management of anxiety. The depressed patient, his understanding and management, is extremely well presented by Dr. Franklin G. Ebaugh. The management of emotional reactions in the male involutional period is covered by Dr. Otto Billig. The management of the multiple complainer by George C. Ham is an example of excellently applied practical psychiatry. Dr. Leo H. Bartemeier's paper on the management of overeating, overdrinking, and oversmoking considers overindulgence as a symptom of emotional disturbance. Dr. Walter C. Alvarez tells how to avoid the production of iatrogenic disease. He believes that anxiety neuroses are sometimes produced inadvertently by physicians and urges the physician to be optimistic, constantly to guard his tongue, especially in the presence of a hypochondriacal patient, and to avoid thinking out loud in alarming diagnostic medical terms. A concluding paper by Dr. Marc H. Hollender emphasizes the utilization of community resources in medical practice. This book is lucid, compact, practical, and clearly written. It is highly recommended.

Surgery of the Hand. By Sterling Bunnell, M.D., Consultant to Surgeon General of U. S. Army, to U. S. Navy, and to Alaska Department of Health. Third edition. Cloth. $22.50. Pp. 1079, with 1056 illustrations. J. B. Lippincott Company, 227-231 S. Sixth St., Philadelphia 5; 2083 Guy St., Montreal, Canada; Pitman Medical Publishing Co., Ltd., Pitman House, 39-41 Parker St., Kingsway, London, W.C.2, England, 1956.

The third edition of this excellent book has been greatly enlarged to include many recent advances in hand surgery. In the past, it has been through this book, as well as through the author's personal stimulus, that hand surgery has reached its present high plane. The parts dealing with the use of antibiotics for infections of the hand has been greatly expanded. Other new or improved chapters include those on postoperative treatment for the repair of tendons and on burns. The format of the book is similar to that of previous editions, but its increased size makes it a bit heavy to hold while reading. If future editions entail further expansion, the author should consider publishing it in two volumes. This book is highly recommended for all those doing hand surgery and should be in the libraries of all hospitals and medical schools. It is an excellent reference book for all levels of teaching, including the postgraduate level.

Ciba Foundation Colloquia on Ageing. Volume 2: Ageing in Transient Tissues. Editors for Ciba Foundation: G. E. W. Wolstenholme, O.B.E., M.A., M.B., and Elaine C. P. Millar, A.H.W.C., A.R.I.C. Cloth. $6.75. Pp. 263, with 96 illustrations. Little, Brown & Company, 34 Beacon St., Boston 6; J. & A. Churchill, Ltd., 104 Gloucester Pl., Portman Sq., London, W.1, England, 1956.

This small volume is the second of a series to be published annually under the auspices of the Ciba Foundation of London dealing with basic research relevant to the problems of aging. The first volume was a colloquium on general aspects of aging. The present one is devoted to the aging of transient tissues, the normal life of which is shorter than that of the organism as a whole. The program is truly international in character. The 27 participants from both the United States and abroad are eminent authorities in their respective fields of anatomy, embryology, physiology, biochemistry, biology, zoology, and botany. Those interested in aging should find delight in the comprehensive conversational manner in which the subject is covered in this symposium. It is difficult to select any one part that is more interesting than another. Perhaps those who do not feel entirely at home with the highly scientific and technical approach to the subjects presented would be engrossed especially by those parts dealing with the regenerative capacity of ovarian tissues, mitochondrial changes in different physiological states, morphological aspects of aging in the placenta, chronological changes in placental function, biochemical evidence of aging in the placenta, aging of the axillary apocrine sweat glands in women, and aging in human red blood cells. One would not do justice to this volume if particular attention were not called to the exceptional artistic merit of the illustrations accompanying the articles. The discussions of the presentations in these colloquiums lend extraordinary value and interest to the program. The informal participation by the audience and the effective but not rigid control of the symposium by the chairman might serve as a pattern for other groups, the meetings of which are so often unenlightening because of their stereotyped panel or conventional order.

Clinical Urology. Volumes I and II. By Oswald Swinney Lowsley, A.B., M.D., F.A.C.S., President and Director, Oswald Swinney Lowsley Foundation, Inc., St. Clare's Hospital, New York, and Thomas Joseph Kirwin, M.A., M.S., M.D., Professor of Urology, New York Medical College, New York City. Third edition. Cloth. $32.50. Pp. 464; 465-985, with 599 illustrations by William P. Didusch. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2, 1956.

In this edition, chapters 1 to 5 deal with the usual, well-accepted diagnostic procedures in urology. This is followed by a good, informative chapter on anesthesiology. In chapters 7 through 34, all the various diseases of each organ of the urogenital system are discussed in a well-organized and well-documented manner. The pattern followed in the discussion of these diseases is comprehensive and to the point. Detail does not succumb to verbosity. In chapter 35 the recent advances made in the field of antibiotic therapy are discussed. Here the reader will find treated the indications, contraindications, and efficacy of the various antibiotics in the treatment of infections of the genitourinary system. Each volume contains an index to the text and illustrations. The publishers have done their part very well. The quality of the paper and the arrangement of the pages into three columns facilitates reading. Since the publication of the second edition, many advances have occurred in urology which are all well documented in this edition. These two volumes are a combination textbook, encyclopedia, and atlas of urologic pathology and surgical techniques, profusely illustrated. The present edition assures for the volumes a continuingly prominent place in urologic literature. They can be unhesitatingly recommended not only as a textbook for students, interns, and residents but also as a reference book for the practitioner, surgeon, and urologist. It is unfortunate that the death of the senior author of this edition came before he had an opportunity to see the finished product.

Electrocardiographic Test Book. Volumes I and II. Paper, loose-leaf. $5 per set. Pp. 167; 132, with illustrations. American Heart Association, Inc., 44 E. 23rd St., New York 10, 1956.

The purpose of this book is to assist students in the study of electrocardiography. The presentation in volume I consists of 110 selected electrocardiograms reproduced as examples of normal and abnormal varieties, together with questions. The answers, documented and discussed on the basis of clinical and roentgenologic data, are assembled on the corresponding pages in volume II. In addition, the two volumes contain general questions and answers pertaining to electrocardiographic differential diagnosis; tables of normal measurements, mostly compiled from the literature and some thus far unpublished; and a comprehensive index. This original approach to teaching clinical electrocardiography should serve the limited aims of the authors, although objections can be raised concerning the examples selected, the interpretation of some of the records, and the illogical questions posed in conjunction with some of the records. There are some inconsistencies in dealing with the difficult problem of differentiation of ischemic alterations from those caused by heart strain and hypertrophy (figures 3 and 24). One also wonders whether statements like the one on page 39 of volume II, "with posterior infarction there is a tendency for the T-waves to become lower and inverted in lead I and positive in lead III," were really acceptable to the advisory and review panel of 28 distinguished authorities. The publication deserves the highest commendation for the excellence and clearness of the reproductions of electrocardiograms and the simplicity and conciseness of the accompanying text that make these volumes most valuable to anyone concerned with learning or teaching clinical electrocardiography.

Studies in Topectomy. Edited by Nolan D. C. Lewis, M.D., Carney Landis, Ph.D., D.Sc., and H. E. King, Ph.D. Cloth. $6.75. Pp. 248, with illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; 99 Great Russell St., London, W.C.1, England, 1956.

The New York Associates in Brain Research explored in 1948 to 1949 the potentialities of psychosurgical methods as a therapy for mental disorder. They used topectomy of the frontal lobes on 66 patients, many of whom were chosen for the severity of their mental disorder. The operations, both frontal ablations, performed bilaterally, were of two types, one removing the superior portion and the other the more orbital section of the lobe. There was no operative mortality or lasting neurological changes. Psychiatric evaluation was undertaken about two years after the operation. The results were not impressive. The procedure was considered of limited value for chronic schizophrenics but of slight usefulness for chronic psychoneurotics and for some of the patients with manic-depressive reactions and with involutional psychoses. An independent psychiatric evaluation by another group of investigators was even less enthusiastic, and concluded from the strictly therapeutic viewpoint that the verdict at best would have to be "not proved." In general the importance of applying therapeutic measures, even topectomy, before the psychotic process has become fixed, was emphasized. The study was carefully planned and executed by a skilled research team. The report reflects their high standards and excellent tallying of the results. The details of the surgical technique, psychometric studies, vestibular function test, and other investigative methods are reported fully and clearly. Although it is published five years after the end of the project, the book is a valuable contribution to our knowledge of topectomy and its effect on psychiatric disease.

Textbook of Gynecology. By Emil Novak, A.B., M.D., D.Sc., Gynecologist-in-chief, Bon Secours Hospital, Baltimore, and Edmund R. Novak, A.B., M.D., F.A.C.S., Instructor in Gynecology, Johns Hopkins Medical School, Baltimore. Fifth edition. Cloth. $11. Pp. 840, with 543 illustrations. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimore 2,

This popular book did not need much revision to bring it up to date. The few important contributions to gynecology made in the last four years are included. The chapter on uterine cancer was entirely rewritten because of the controversy concerning carcinoma in situ. Likewise, the chapter on pelvic tuberculosis was completely rewritten because of advances in both diagnosis and treatment of the disease. The authors mention the new skin biopsy tests for sex determination. They consider kraurosis and leukoplakia of the vulva together because of the frequency with which the two terms are wrongly applied and the existing confusion as to their differentiation. The authors do, however, make a rational distinction between the two conditions. There is a full description of carcinoma in situ, with emphasis on the difficulties in diagnosis. The authors again summarize the important essentials of the responsibilities of the general practitioner in the campaign against cervical cancer. In the chapter on tuberculosis of the generative organs, the place of streptomycin, aminosalicylic acid, and derivatives of isonicotinic acid is discussed. There is no doubt that the Novaks have again produced a classic book that should continue to be profitably studied throughout the world.

QUERIES AND MINOR NOTES

FETAL EFFECTS OF DEMEROL ANTE PARTUM

To the Editor:—*In the local hospital the use and dosage of Demerol in a woman in labor with an intrauterine pregnancy was questioned when an infant had a four-or-five minute delay in cry and respiration attempts. A review of the available literature reveals that it is the consensus that Demerol will not have a depressant effect on any infant, whether at term or premature. The mother had received a total of 200 mg. of Demerol within a three-hour period prior to the actual delivery. The last dose was 100 mg. and was given 20 minutes prior to delivery. How soon after injection can one normally expect a peak of effect in the infant (if any)? What is the maximum dose that could safely be given to a normal mother weighing 70 kg. (154.2 lb.) in labor without danger of depression to the baby? Is there any place in the literature indicating that morphine (given to the mother in labor) was not depressant to the baby?* *M.D., Wis.*

Answer.—The depressant effect of Demerol on the fetus depends on certain variables that cannot be predicted in any given case. These variables include the tolerance of the mother, her weight, the rapidity of absorption from the injection site, and the type of anesthesia used for delivery. In general, the maximum effect of an intramuscular injection should occur about one hour after administration to the mother. This is rarely of clinical significance if conduction or local anesthesia is used. With general anesthesia, with cyclopropane or nitrous oxide ether, the narcotizing effect of this combination of drugs may be of significance to the baby. Most normal labors, of 6 to 10 hours' duration, can be readily managed with a single dose of 100 mg. of Demerol, preferably combined with scopolamine (hyoscine) in a dose of 0.4 mg. If this is inadequate to control the patient's discomfort, trichloroethylene (Trilene) inhalation or the judicious use of chlorpromazine or one of its derivatives is considered preferable to the repeated doses of Demerol. When repeated doses of narcotics of any type must be given for the control of pain in labor, when they are used at repeated irregular intervals for the purpose of obtaining rest in a prolonged labor, or when the mother shows a profound response to these drugs, their narcotizing effect upon the baby may be effectively and promptly minimized by the administration of amphetamine or nalorphine (Nalline) hydrochloride to the mother approximately 15 to 30 minutes prior to delivery. Morphine sulfate has been shown both clinically and experimentally to be a depressant to the baby. This consultant is unaware of any valid data to the contrary.

PREMATURE GRAY HAIR

To the Editor:—*In the May 19 issue of* The Journal, *page 299, is a query on graying of hair. Is there any known medication or treatment that will forestall or delay premature graying of hair? If not, what is a safe method for use in changing the color of the hair to its former color?* *M.D., South Carolina.*

Answer.—There is no known medication or treatment that will forestall or delay premature graying of the hair. Reports of the effectiveness of pantothenic acid or p-aminobenzoic acid in delaying or lessening premature graying of the hair have never been proved. As far as a safe method of changing the color of the hair is concerned, there is no absolutely safe procedure. An occasional person will still react unfavorably to the methods mentioned subsequently. The metallic hair dyes are successful only when frequent applications are made, and the desired color may appear after a series of treatments that progressively darken the hair. The usual solutions contain silver, copper, iron, or lead, which act with the sulfur content of the hair to deposit a metallic sulfide on the shaft. Silver nitrate, in combination with a 1% solution of pyrogallic acid as a reducing agent, may be adopted for all shades from white or brown to black, depending on its strength. The synthetic organic dyes are also effective and are of two types. The first, or "azo" type, has a low index of sensitivity but has the disadvantage that several applications are necessary to obtain the desired shade. The most popular types of dyes are those of the amine or aniline type. They have two characteristics that render them superior to their predecessor: First, the desired color is usually acquired at one sitting. Second, the colors themselves offer a wide range of choice and are much more natural in appearance. Several preparations are on the market, and patch tests should be performed prior to their usage. This synthetic dye is usually sold in two bottles, of which one contains a 1 to 3% aqueous solution of the para dye and the second an oxidizer such as hydrogen peroxide or sodium persulfate or perborate. Some of these are available for home application, although it is usually preferable to have the applications made by a professional. Inasmuch as the chemicals employed are not easily handled by the amateur, the skill and experience of a careful operator should minimize the possibility of untoward side-effects.

ULTRAVIOLET BLOOD IRRADIATION

To the Editor:—*A 39-year-old man is being treated for "a general run-down condition." Apparently he is not progressing as well as anticipated. His brother has chronic bilateral thrombophlebitis of both legs and, in addition to saphenous vein ligations and anticoagulant therapy, he has received ultraviolet blood irradiation, possibly according to the Knott technique. It is stated that some improvement has followed this therapy. The treating physician for the first-mentioned man feels that ultraviolet blood irradiations may be of value in improving his patient's condition. I would appreciate an opinion on the efficacy of ultraviolet blood irradiation in regard to its application to the broad category of "general run-down condition."*

M.D., Massachusetts.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—There is no objective evidence that ultraviolet irradiation of the blood by the Knott technique has any beneficial effects. It has been used widely for a great number of conditions, with purportedly uniform good results. The nature of the ultraviolet treatments is such that a great deal of psychotherapeutic benefit may ensue from their use. This, together with the enthusiasm of those who have used the treatments, probably accounts for the reported value of the technique. Its use for any patient with a "general run-down condition" is not indicated. It is essential to establish why a 39-year-old man is "run-down," so that rational therapy may be instituted.

Answer.—Ultraviolet blood irradiation enjoyed a brief display in the medical literature from 10 to 15 years ago. A portion of blood (about 250 cc.) was removed from a patient, citrated, and then, after exposure to powerful ultraviolet irradiation in a suitable irradiating chamber, was immediately pumped back into the venous system. While the claims of the favorable effects of hemoirradiation on bacterial infections did not violate credibility, in view of the known bactericidal potency of ultraviolet rays under suitable conditions, reports soon appeared suggesting the efficacy of hemoirradiation in acute thrombophlebitis, bronchial asthma (intrinsic), rheumatoid arthritis, osteoarthritis, postfebrile poliomyelitis, "non-healing" wounds (apparently due to chronic osteomyelitis or vascular insufficiency), and paralytic ileus. As a result of the alleged dramatic response of chronic as well as acute diseases, a hypothesis of "ultraviolet ray metabolism" was developed.

As often occurs in medicine, a reputedly successful, if not dramatic, new therapy in the hands of a few is quickly taken up by the many and applied to a wide array of conditions of

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

unknown etiology in the hope of a cure. Hemoirradiation was no exception, and disappointment followed inevitably. More important, it stimulated well-controlled experiments in which bloods seeded with various pathogens were irradiated. These failed to corroborate the clinical reports. Indeed, in saline medium, where ultraviolet could be expected to reach the bacteria in more potent doses because of minimal absorption, irradiation also failed to eliminate the organisms. In nonbacterial diseases it was never proved that ultraviolet irradiation had an "energizing" effect on the body, and no satisfactory short-term or long follow-up proof on chronic arthritides and other conditions were published. The whole concept of this form of treatment, in fact, was never subjected to a well-controlled analysis free from objectionable methodology. Uncritical empiricism based on a tenuous and untested hypothesis may briefly lead to the unbridled use of an agent, even for such vague conditions as "general run-down condition." Today, ultraviolet hemoirradiation is a medical curiosity that did not fulfill the therapeutic claims originally made for it.

CAUSE OF DEATH

To THE EDITOR:—*In "Collectivism on the Campus: The Battle for the Mind in American Colleges," by E. Merrill Root (New York, the Devin-Adair Co., 1955, p. 133), is a passage dealing with the death under mysterious circumstances of a young student in California. After an autopsy, the cause of death was given as inhibition. This matter was not discussed at length, but apparently it referred to such stimulation of the central nervous system by terror that nervous reflexes stopped the action of the heart and/or lungs. I would appreciate it if you would comment on this diagnosis.*

Thomas Parker, M.D., Greenville, S. C.

This inquiry was referred to two consultants, whose respective replies follow.—ED.

ANSWER.—There are many instances in fiction and occasional, but unverified, references in scientific literature to sudden death during a period of extreme emotional stress. One might postulate, although it is extremely improbable, that sudden hypothalamic overactivity, in response to fear or some other emotion, might cause vagal stimulation to such a degree that it would bring about cardiac arrest and/or inhibition of respirations. This, however, has never been demonstrated or proved. One might question whether such a phenomenon, if it exists, could be related to the so-called acute brain death, which sometimes occurs without warning in schizophrenia and other so-called functional mental diseases. In this, however, there is usually a brief period of of extreme hyperpyrexia, motor hyperactivity, and either stupor or convulsions preceding death. In these cases, furthermore, extensive cellular alterations in the brain have been reported. Before answering this query, the original reference was reviewed. When the body of the subject was found, it was lying in a furnace pit near an unconnected gas heater. The gas that fed the furnaces was turned off, and the furnace room door was standing open. A few days later, as soon as an investigation began, the entire basement was flooded, and other possible clues were obliterated; apparently the flooding was purposely done. The only finding in the autopsy was pulmonary edema.

It is apparent, from the circumstances leading to death and the findings after death, as well as from lack of any proof of inhibition of purely psychic origin and not secondary to toxic or other organic stimulation of centers that depress cardiac and respiratory functions, that one must conclude that in this case the cause of death was not found. One must assume that external causes of toxic or other origin, which were not brought to light in what was apparently a very complete autopsy, were responsible for the death of the subject. It was the final conclusion that this was "death by homicide" (page 137). While inhibition may be a theoretical cause of death, it is not so accepted clinically. It would be better in cases like this to conclude, as was done in this case, that death was due to external causes. One should be willing to admit that the cause was not found and should not rely on intangible, unscientific explanations.

ANSWER.—The Standard Nomenclature of Diseases and Operations published by the American Medical Association does not list "inhibition" as a disease entity. Inhibition as a cause of death is not acceptable in medical circles and probably would not be accepted by boards of health on a death certificate. Many deaths occur under mysterious circumstances, and the cause in any one can be overlooked in an autopsy unless the examination covers all phases necessary to accomplish this.

TACHYCARDIA

To THE EDITOR:—*A 75-year-old woman suffers from chronic suppurative bronchitis and asthma and is highly allergic to egg albumin. She has frequent attacks of tachycardia, which usually occur after dinner and may last half an hour. During the attack the pulse is about 120 per minute, full and tense, and there is shortness of breath and at times pain extending down the arms. Is there any therapeutic measure that might reduce the frequency of these attacks or give relief?*

M.D., New Jersey.

ANSWER.—It would be helpful to have more information concerning the nature of the tachycardia and the characteristics of the rate and rhythm. If there is any irregularity of the rhythm, then one must consider the possibility of a paroxysmal fibrillation or an atrial flutter with varying block. An electrocardiogram taken during an attack would help to settle this question.

If the rate is perfectly regular at 120 beats per minute, then the underlying mechanism is probably a normal sinus rhythm. Therefore, one must suspect that the underlying cause is coronary insufficiency, probably induced by the demands of digesting a heavy meal. Reducing the amount of food at the evening meal and dividing the total daily amount of food into four or five small meals may be helpful. Administration of glyceryl trinitrate (nitroglycerin), 1/200 grain (0.3 mg.) sublingually, may be tried at the onset of her attack. If the glyceryl trinitrate aborts the attack and relieves the dyspnea and pain, then the usual program for angina should be instituted. If it can be demonstrated that the attack is a paroxysmal type of fibrillation or atrial flutter with varying block, then administration of quinidine sulfate, 200 mg. after meals and at bedtime, is indicated in an effort to prevent the attacks. An additional 200-mg. tablet may be given during the attack. In spite of the highly allergic background of the patient. it is doubtful that any allergic reaction is playing a role in the attacks.

AZOOSPERMIA

To THE EDITOR:—*Examination of a 34-year-old man was essentially negative apart from slight obesity. Urinalysis and serology were negative. A fertility investigation by a urologist revealed azoospermia. The patient asks: "I was working with a poison gas unit during the war—could this have caused me to be sterile?"* *Thomas W. Parkinson, M.D., Gastonia, N. C.*

ANSWER.—The germinal epithelium of the testes may be severely damaged as a result of repeated absorption of small doses of toxic substances over a long period of time through the skin, lungs, or alimentary tract. Alcohol and morphine are known to act in this way. Various industrial poisons have been inculpated in the same respect, among them lead, mercury, sulfocarbonate, benzene (benzol), toluene (toluol), phosphorus, and turpentine. This consultant has no information about the chemistry of the gases used in warfare or about the precautions taken to protect men working with them. There would seem to be at least a theoretical possibility that the spermatogenic apparatus might be exposed to injury. Further investigation is needed to throw light on the cause of azoospermia in this patient. Testicular biopsy may show normal spermatogenesis, and in that event the trouble is obviously a blockade in the duct system; it may reveal aplasia or hypoplasia of the seminiferous tubules; it may show germinal epithelium that is histologically fairly normal but functionally inactive, and if at the same time hormone assays demonstrate a low level of gonadotropins the diagnosis of pituitary eunuchoidism is apparent. In all of the foregoing cases the primary cause of azoospermia would be adequately explained by the findings and is clearly unrelated to any sort of chronic intoxication. However, if the biopsy finding is sclerosing tubular degeneration and atrophy, one may consider the possibility that a toxic factor was initially responsible, though this is by no means proved by the evidence obtained.

BRONCHIAL ASTHMA WITH TUBERCULOSIS

TO THE EDITOR:—*How frequently does bronchial asthma occur with pulmonary tuberculosis? A number of patients in all the different stages of pulmonary tuberculosis have all the classic signs of bronchial asthma. Are the physical signs and symptoms due to bronchial asthma, per se, or are they the result of intermittent flaring up of the tuberculous process? During these episodes these patients have been given the usual treatment for bronchial asthma and this has relieved them. Is there some other treatment? Is this an allergic manifestation to the tubercle bacilli?*

M.D., Philippines.

ANSWER.—The incidence of bronchial asthma in patients with pulmonary tuberculosis is identical with its incidence in the general population. This represents true allergic bronchial asthma, with the sensitivity being due to the common antigens, and does not represent an allergic manifestation to the tubercle bacilli. The conventional treatment for asthma is indicated and should produce results uniform with those obtained in nontuberculous patients. The only exception to this statement is that steroid therapy should not be used in those patients having known tuberculosis or in those suspected of having tuberculosis. It is also true that the physical signs and symptoms of bronchial asthma may occur in patients with pulmonary tuberculosis and be due to the tuberculosis and not to allergic bronchial asthma. In these patients, the common cause for these findings is due to involvement of the bronchus by either a tuberculous bronchitis and/or pressure on the bronchus by an enlarged mediastinal lymph gland. These patients will also show a response to the conventional therapy with bronchodilator drugs, but this response will be only temporary and symptomatic and therefore this therapy must be accompanied by therapy with antimicrobial drugs.

DRUG ADDICTION

TO THE EDITOR:—*A 45-year-old male patient with osteoarthritis takes the following amounts of medication nightly in order to obtain satisfactory rest: codeine, ½ to 1 grain (30 to 60 mg.); three to four Bufferin tablets; and one or two Valmid tablets. Is there any danger of addiction or other harm from continued use of the above?* *M.D., New Hampshire.*

ANSWER.—The danger of addiction in the case described depends primarily on the personality structure of the patient. If he is a mature, emotionally stable individual, the danger of addiction would be remote. On the other hand, if he is an unstable person there would be some danger of addiction to codeine. Indications that addiction might be developing would be requests for increase in amounts of codeine or attempts to obtain supplies without obtaining new prescriptions and by obtaining prescriptions from more than one physician. This danger, which is slight, is further minimized if close contact with the patient and with his family can be maintained. There should be no harm from continued use of either the codeine or Bufferin. Sufficient information concerning idiosyncrasies to Valmid is not available to evaluate the danger of long-continued use of this particular substance. If the patient can be examined at frequent intervals, any untoward drug intoxication should be detected before significant harm is done.

TRAUMATIC AMPUTATION OF FINGER TIP

TO THE EDITOR:—*What would be an approved method for immediate definitive treatment of a 35-year-old aircraft factory worker whose injury consisted of an almost complete guillotine type of crushing amputation, bone and soft parts, of the right index finger, through the base of the distal phalanx, involving the distal joint? There remained only a slight subcutaneous bridge attaching the amputated end to the balance of the digit? All major digital vessels apparently had been severed, as there was no bleeding from the distal stump, while the proximal end bled freely.* *M.D., California.*

ANSWER.—Replacement of the tip of the finger would, in all probability, not be successful, as the bulk of the tissue was too great and the injury was a crushing one. If the skin of the pulp was not too crushed, all the subcutaneous fat could be removed and the skin of the pulp laid across the end of the stump. Usual procedures in such a case would be to cover the end of the stump with a free skin graft or to transfer a flap to it from the thenar eminence. The objection to the latter is that in a 35-year-old man the joints would stiffen in the three weeks that the flap is attached. Perhaps the best way would be to use a cross-finger flap from the dorsum of the long finger and skin graft the donor site. Another possibility would be to raise an immediate pedicle flap from the abdomen and place it over the end of the finger. Such a procedure is usually left for a secondary operation, if it proves to be necessary. If bone is projecting, it should be trimmed off, and, if a joint surface is presenting, it should be denuded of cartilage.

TREATMENT OF PEDUNCULATED POLYPS

TO THE EDITOR:—*Two polyps were excised recently from a 55-year-old male. The polyps were attached to the sigmoid flexure by a stalk about 2 in. in length. The microscopic report revealed that the stalk portion of the glandular mucosa is not unusual. A portion of the distal part of the polyp showed hyperchromatism of some of the irregular glandular acini. Heaping up of the glandular epithelium was seen at this portion, with component cells exhibiting moderate variation in size and shape. Mitotic figures are fairly frequent in this area. The diagnosis was malignant adenomatous polyp. At operation the polyp was excised at the base of the stalk. Is any further surgery indicated at present?*

M.D., New York.

ANSWER.—Review of the experience at a large cancer center where several thousand pedunculated, adenomatous polyps have been removed showed there has been no instance of lymph node metastases when cancerous changes have been superimposed upon the periphery of the polyp. It would seem, therefore, that the 55-year-old patient having two pedunculated polyps has been adequately treated and that future emphasis should be directed at the detection of other polyps, which are quite likely to develop in other areas of the same lower intestine. Pedunculated carcinomas and sessile polyps, containing foci of adenocarcinoma, on the other hand, have been seen to metastasize to the regional lymph nodes and must be treated radically from the onset as infiltrating carcinoma.

BRANCHIOGENIC CYST

TO THE EDITOR:—*What would be the recommended treatment of a healthy 14-year-old girl with a now quiescent congenital cyst (and/or fistula), branchiogenic, in the lateral cervical region, which has twice previously necessitated incision for local abscess formation?* *M.D., California.*

ANSWER.—A branchiogenic cyst with recurrent fistulous communication is a distinct indication for a complete and adequate excision of the cyst. Incision alone would of course only allow repeated recurrent draining abscess formation, and the actual cyst itself must be removed totally by meticulous and careful surgery.

DIABETIC NEUROPATHY WITH INCONTINENCE

TO THE EDITOR:—*What is the treatment for diabetic neuropathy of the legs with incontinence of the bladder and rectum? Are steroids of any value?* *M.D., New Jersey.*

ANSWER.—The treatment of diabetic neuropathy with incontinence of the sphincters is very unsatisfactory. Some improvement has been noted after intensive treatment with crude liver extracts given intramuscularly (3 cc. daily) and large doses of vitamin B_{12}, of the order of 1,000 mcg. per day. The steroids are probably of no help.

EXERCISE AND THE DIGITALIZED HEART

TO THE EDITOR:—*How does exercise affect the rate of the completely digitalized heart?* *M.D., Missouri.*

ANSWER.—Exercise produces less acceleration of the heart that has been digitalized. This is best seen in auricular fibrillation. The amount of this effect depends on the dose of digitalis. The more complete the digitalization, the less the acceleration of the heart with exercise.

THE MEDICARE PROGRAM

The Office for Dependents Medical Care has issued additional information designed to answer questions arising from the armed forces new and broadened program of medical care for service families. The program became effective Dec. 7. In a letter to state medical societies and groups serving as fiscal agents for provision of care by private physicians, Major. Gen. Paul Robinson, director of the office, stresses the "medicare" program is one of full service coverage. He makes these points: 1. It is intended that medicare as authorized by the last Congress will be on a basis comparable to that provided in uniformed medical facilities. Except for specified amounts to be paid by the patient, services provided under the law will be paid for in full from the government in accordance with published schedule of allowances. "In most instances, this means that the physician participating in the program will receive payment for his usual charge or the amount established in the local schedule of allowances, whichever is less," the letter states.

2. There may be unusual instances in which the physician will believe that an allowance greater than that prescribed in the local schedule is justified. "In such cases, the physician should look to the government for additional payment and not to the patient." Provision is made for the doctor to submit a special report to his state medical society and in turn to the government as request for added payment, and such payment will be made upon approval by the medical society's review board and the government contracting officer.

The Office for Dependents Medical Care also points out that it is not contemplated that the government will authorize payment for drugs, medicinals, or other medical supplies except those furnished to an inpatient while hospitalized or those administered directly by a physician in his office.

On the question of identification of military dependents, the office says that doctors may accept as evidence the post exchange card issued to dependents, the combined post exchange–commissary–military medical care card, also the military dependent identification card. After July 1 of next year, a new Defense Department identification card for medicare alone will be the only card honored for this purpose.

FEDERAL WORKERS HEALTH INSURANCE

A fresh try at drafting legislation that will provide both basic and major medical expense coverage for federal employees is being made by the Civil Service Commission. Despite repeated failures at getting a bill suitable to all parties passed in Congress, administration officials are optimistic over prospects in the 85th Congress convening Jan. 3.

The administration's 1956 proposal, which would have provided for catastrophic illness coverage with the government paying the premiums, came up against opposition from some nonprofit plans and labor spokesmen. Accordingly, no bill passed this year. The Civil Service Commission the year before was unable to get an agreement on a basic coverage plan. The new approach is to tie both programs into one bill that will satisfy federal employees unions, commercial carriers, and Blue Cross and Blue Shield.

One of the large federal workers unions, the American Federation of Government Employees, has suggested a combined program that would permit the employee to take out group health insurance with any type of carrier that met commission criteria for soundness of operation. The government and the worker would share equally in payment of premiums, which would be handled through payroll deduction.

THE DOCTOR-DRAFT FOR FEBRUARY

A total of 450 physicians are scheduled to be called in February under the doctor-draft, with 250 men sought by the Army and 200 for the Air Force. The six-year-old doctor-draft act expires next June 30, and the Defense Department has said it has no plans for asking Congress for another extension. The Selective Service headquarters, meanwhile, has instructed local draft boards to review immediately the essentiality or availability of young priority 3 physicians serving residencies. Comments the Selective Service: "In this connection we would like to point out that there are a number of younger priority 3 men in residency training who are not essential but are so classified. We are informed that some of them have been deferred as necessary to the operation of the hospitals."

The agency defined "young" as men up to the age of 37. It said that "it is hoped that there is yet times to get a sufficient number of younger men reclassified into class 1-A to satisfy these proposed calls without going into the upper age bracket."

In making their reports of availability of doctors for the February call, boards will exclude physicians who will be 35 years of age or older on Feb. 27, 1957, and who have applied at any time for a commission in the armed forces in a medical, dental, or allied specialist category and have been rejected solely because of physical disqualification.

From the Washington Office of the American Medical Association.

PROGRAM TO INCREASE RESEARCH MANPOWER

Starting a new federal program designed to increase manpower for research in basic medical sciences, the National Institutes of Health announces award of 44 five-year fellowships to scientists in universities and medical schools. Recipients are scientists with a doctor's degree in biochemistry, pharmacology, physiology, microbiology, pathology, and the psychological sciences.

Each award calls for a salary not in excess of $10,000 per year, plus up to $2,000 for part of the expense of research. The institution sets the salary level at approximately that of scientists doing similar research and teaching as members of the regular faculty. While the fellows continue their research, sponsoring institutions will assign them appropriate teaching responsibilities so they may qualify for full-time academic positions at higher levels.

Inauguration of the program was preceded by more than two years of study by the Public Health Service, aided by a group of outside experts and deans of medical schools and heads of university departments involved in medical research. In explaining why the program is needed, PHS Surgeon General Burney said that this year more than 200 research positions are open on the faculties of medical and basic science fields, including 55 professorships, 52 associate professorships, and 79 assistant professorships.

The plan is to award between 40 and 50 fellowships annually until 250 have been set up by the fifth year. Thereafter the program will be maintained at this level "until the national deficiencies have been met." This year, fellowships will cost about half a million dollars.

Four institutions—University of California, Harvard, University of North Carolina, and Canada's Albert Einstein College of Medicine—received three fellowships each. Other schools receiving one or two scholarships are Yale, Georgetown, University of Florida, Emory, University of Kansas, Tulane, Johns Hopkins, Michigan, Minnesota, Washington University, New York University, Albany School of Medicine, Rochester, Bowman Gray School of Medicine, Duke, Wake Forest, Western Reserve, Ohio State, Oklahoma, Pennsylvania, Pittsburgh, Tennessee, Vanderbilt, Baylor University, University of Washington, and Marquette.

MALARIA ERADICATION PROGRAM

The hemisphere-wide malaria eradication program is gaining momentum, and integrated programs of various governments leave no doubt as to the eventual success of the campaign. That is the latest word from the Pan American Sanitary Bureau, which cites some examples: 1. Some 3 million houses in malarious areas of Mexico will be sprayed starting Jan. 1, the largest undertaking of its kind ever attempted in this hemisphere. The United Nations Children's Fund is providing large supplies of insecticides, trucks, and other essential materials, but with the Mexican government furnishing most of the funds and direction.

2. Of the 20 countries originally infected by malaria, 2 (the United States and Chile) have completed eradication; 10 others in addition to Mexico have begun eradication (Argentina, Brazil, Ecuador, El Salvador, Guatemala, Haiti, Honduras, Dominican Republic, and Venezuela); 3 have completed plans for converting control programs to eradication programs (Nicaragua, Panama, and Paraguay); and 5 are either surveying or considering conversion to eradication campaigns (Bolivia, Colombia, Costa Rica, Cuba, and Peru).

The Bureau has set up a coordinating office for malaria eradication in Mexico City to advise and guide programs under way or in preparation in various countries.

NEW AIR FORCE MEDICAL CENTER

The Air Force is scheduled to award the first contract this month for the construction of an $8,800,000 Aero Medical Center that will house the Air Force School of Aviation Medicine. It will be built at Brooks Air Force Base, San Antonio, Texas, and is slated for completion at the end of 1958. The work of the school is now carried on between Randolph Air Force Base, Texas, and Gunter Air Force Base, Ala.

Comments the Air Force: "Establishment of this single aeromedical center will allow the Air Force to conduct more extensive research into the medical aspects of supersonic flight problems, and to provide greater aviation medicine teaching facilities than are now available. Emphasis will be placed on developing means of protecting fliers at the high speeds and altitudes which are now encountered, or expected to be, in the future." The center was authorized by the 82nd Congress in a fiscal 1953 military construction program bill.

MISCELLANY

The Federal Civil Defense Administration's health office had a special exhibit at the American Public Health Association convention depicting physical characteristics of radiological fall-out, hazards of fall-out, and suggested protective measures. . . . Dr. Harry Davis Bruner is the new chief of the medical branch of the Atomic Energy Commission's division of biology and medicine. . . . The Walter Reed Army Institute of Research has developed a vaccine that is said to effect a 98% reduction in acute respiratory illnesses caused by adenoviruses. As the vaccine has been tested only with military personnel, its effect on a large section of the population is not known. . . . Forty participants have completed the three-week 13th Interagency Institute for Federal Hospital Administrators. . . . When the first plane load of Hungarian refugees landed in the United States the first person they saw was Dr. Isidor Abrahamer of the Public Health Service, who is himself a refugee. Dr. Abrahamer, who is assigned to the foreign quarantine service, is responsible for the medical examinations of the Hungarian refugees. . . . Mrs. H. Chapman Rose of Cleveland has been appointed a member of the National Advisory Mental Health Council, which advises the activities of the National Institute of Mental Health. . . . Col. Frank M. Townsend, U. S. A. F., Deputy Director of the Armed Forces Institute of Pathology, has been elected chairman of the Joint Committee on Aviation Pathology of the Department of Defense.

SURGICAL RENAL LESIONS ASSOCIATED WITH PREGNANCY

Willoughby E. Kittredge, M.D.
and
J. Robert Crawley, M.D., New Orleans

• *Hormonal factors that control the course of pregnancy as well as the pressure of the gravid uterus on the ureters cause physiological changes in the kidneys and ureters of at least 90% of pregnant women. Mechanical pressure occurs only at the pelvic brim, but the hormonal influences producing dilatation, atony, and reduced irritability of smooth muscle involve the entire upper urinary tract. Previous diagnosis of urinary disease or congenital anomalies is important in anticipating these changes. Pyelonephritis is still frequent, but its management in pregnant women is no longer different from that in the nonpregnant. Preexisting surgical renal disease must be carefully evaluated before pregnancy is permitted; disease discovered during pregnancy may or may not necessitate therapeutic abortion. The decision in either case depends on the nature and extent of the renal disease, the general health of the patient, and, in borderline cases, the risks that the parents are prepared to take in order to obtain a child.*

With the possible exception of the cardiovascular system, the genitourinary tract is probably the organ system of the body most vulnerable to complications of pregnancy. In Folger's[1] experience, of all women hospitalized at Western Reserve for treatment of complications of pregnancy, the largest group had involvement of the urinary tract. It is therefore of the utmost importance, to both obstetricians and urologists, not only to review the management of surgical renal lesions discovered during pregnancy but also to evaluate properly the changes that can be expected to occur in the upper urinary tract during pregnancy and their significance with regard to preexisting surgical renal disease.

Physiological Changes in Ureters and Kidneys

The physiological changes occurring in the upper urinary tract during pregnancy have been recognized since 1843, when they were first described by Cruveilhier.[2] These changes consist in dilatation of the upper two-thirds of the upper urinary tract, with impairment of drainage and resultant stasis of urine and back-pressure in the renal pelves. It is now generally agreed that these changes are the result of hormonal alterations as well as of mechanical factors incident to pregnancy. However, the hormonal influence is of greater importance, since it has been shown that such changes can be reproduced in the nonpregnant woman by administration of progesterone and also that they tend to lessen toward the end of pregnancy as the hormonal balance changes in the circulating blood.[3] Van Wagenen and Jenkins[4] were able to show that after spontaneous death and absorption of a fetus or surgical removal of a fetus, if the placenta remains in place and active, the changes in the upper urinary tract remain. It is also well known that certain of these changes occur during the first trimester of pregnancy, before there is sufficient enlargement of the uterus to result in any real mechanical obstruction. Because of the common embryologic origin of the uterus and upper urinary tract collecting system, the basic hormonal influence intended primarily to produce dilatation, atony, relaxation, softening, and reduced irritability of muscle response of the uterus in the normal course of pregnancy inevitably has the same effect on the ureters and renal pelves.

That mechanical factors also play a part is evidenced by the fact that the changes end where the ureters cross the pelvic brim. This can be explained by the pressure of the uterus on the ureters at that point. The changes are more pronounced on the right because of the dextrorotation of the uterus, the prominence of the right iliac artery, and the cushioning effect of the sigmoid colon on the left. These changes appear grossly as elongation and tortuosity of the ureters and dilatation of the ureters and renal pelves.[5] The microscopic appearance is characterized by hyperplasia and hypertrophy of the smooth muscle and connective tissue,

with infiltration by lymphocytes, plasma cells, and leukocytes, and increased vascularity and edema. Physiologically, the irritability response of the smooth muscle of the ureter to stimuli is reduced. These changes become gradually more pronounced up to the seventh month of pregnancy and diminish during the eighth and ninth months. The upper urinary tract usually returns to normal by the end of the third postpartum month, although in some instances the upper ureters and renal pelves, particularly on the right, may become permanently dilated after multiple pregnancies.

Certain degrees of dilatation of the upper urinary tract may also occur as a result of large abdominal masses other than a pregnant uterus, owing entirely to the mechanical factors discussed in the preceding paragraph, but this is not nearly as pronounced or consistent as in pregnancy. At present, therefore, it seems safe to assume that the anatomic and functional changes that take place in the ureters and kidneys are due largely to the same substance that controls the course of pregnancy in the uterus. Attempts to identify this substance accurately have not so far been successful.

Pyelonephritis of Pregnancy

The fact that these physiological changes occur in at least 90% of pregnant women easily explains the increased disposition of these women to infection of the upper urinary tract. Infection has been variously reported as occurring up to six times more often in pregnant than in nonpregnant women. However, although pyelonephritis of pregnancy was formerly a serious problem, sometimes becoming of surgical importance, with the modern advances in chemotherapy of urinary infection, its management is no longer different from that in nonpregnant women. Today such patients rarely require hospitalization and still more rarely require indwelling ureteral catheter drainage to control the infection. A striking contrast to this fact is the report of Crabtree and Prather[6] in 1930. At the Boston Lying-in Hospital, between 1916 and 1922, before the days of modern chemotherapy, they noted that, of 46 hospitalized women with pyelonephritis of pregnancy, only 17 became afebrile and were allowed to complete the pregnancy. Pregnancy was interrupted or spontaneous abortion occurred prematurely in 25 patients. Six infants died, and, although there were no maternal deaths in the hospital, three mothers died at home some months later from the effects of renal infection. In reviewing the hospital records at Western Reserve, Folger[1] also showed that, in the 10-year period ending in 1943, of 12,981 pregnant women, 372 (2.9%) were admitted to the hospital because of pyelonephritis. In the succeeding 10 years, of 17,556 pregnant women, only 106 (0.6%) required hospitalization for the same reason.

Obviously, therefore, although the underlying factor of retarded drainage of urine with resulting stasis in the kidneys still causes the same predisposition to infection of the upper urinary tract in pregnancy as it always has, these cases are now rarely of surgical importance, with the exception of those few instances in which preexisting anatomic defects interfere with drainage. In such instances surgical intervention or interruption of the pregnancy may become necessary because of inability of chemotherapy alone to control the infection. The affected kidney can often be surgically drained either by indwelling ureteral catheter or by introduction of a nephrostomy tube, without necessarily removing the kidney or interrupting the pregnancy. During the puerperium the kidney may be reevaluated and removed if found to be destroyed or else the original defect plastically repaired if indicated.

Congenital Anomalies of Upper Urinary Tract

Congenital anomalies of form and position of the upper urinary tract may be well tolerated during pregnancy, in the absence of infection, and often remain undiagnosed. However, if the physiological changes of pregnancy are superimposed on pathological changes already present, there is an increased predisposition to dilatation of the renal pelves, impairment of function and drainage of urine, and infection. This is true of renal ectopia, fused kidneys, polycystic kidneys, congenital obstructions of any part of the upper urinary tract, vascular anomalies producing obstruction, certain cases of malrotation and malposition of the kidneys, and congenital renal ptosis. In some instances, however, ptosis may be temporarily improved during pregnancy, owing to the supportive effect of the enlarged uterus. Therefore, in all women known to have such anomalies the competency of both kidneys should be carefully evaluated before pregnancy is advised.

Renal Ectopia.—Renal ectopia is of particular importance, because of the potential danger of the traumatic effect of normal labor to such kidneys. Because of their abnormal form and position, more often than not, prior to pregnancy, such kidneys exhibit varying degrees of hydronephrosis, infection, and impairment of function. Reviews of the world's literature on this subject by Tweed[7] and by Anderson and associates[8] show that ectopic pelvic kidneys have been reported as occurring approximately once in every 4,000 pregnant women, although many asymptomatic ones undoubtedly remain unrecognized. Of 113 cases discussed by Tweed[7] of pelvic kidneys recognized during pregnancy, 80% were unilateral, 7 solitary, and the remainder bilateral with or without fusion; of the unilateral cases, 79% occurred on the left side. One-half of these were recognized during pregnancy and the remainder either during the postpartum period or at autopsy. There were 226 pregnancies in these women; the incidence of abortion was 15.4%, the total fetal mortality rate 16.7%, and the total maternal mortality rate 10.2%. However, there have been no maternal deaths since 1927. Delivery was spontaneous in 73% of these women, by cesarean section in 17%, and by forceps in 6. Downs and Burns[9] reported that, of seven women having solitary pelvic kidneys, three (42.8%) died of renal failure as a result of pregnancy and spontaneous delivery; of the 14 pregnancies in the latter group, 12 living babies were born, 9 being delivered vaginally and 3 by cesarean section. These figures clearly indicate that the presence of pelvic ectopic kidneys in itself does not necessarily contraindicate pregnancy or mean that a pregnancy already in progress must be interrupted. However, although the majority of such women may be allowed to deliver vaginally, cesarean section is mandatory if all the renal tissue lies within the bony pelvis. Removal of a unilateral ectopic kidney is not indicated at the time of cesarean section unless the kidney is badly diseased and the opposite kidney is known to be normal.

Women with One Kidney.—Women with only one kidney, due either to previous nephrectomy or to congenital agenesis of the opposite kidney, can usually tolerate pregnancy without difficulty if the single kidney is normal. This is particularly true if the solitary kidney is on the left, since it normally undergoes less change during pregnancy than does the right, for reasons previously discussed. In persons with a congenital solitary kidney, the total renal function and renal mass are approximately the equivalent of two normal kidneys, and, in acquired cases, compensatory hypertrophy is complete within 18 months after nephrectomy, so that renal function and renal reserve are again normal. Therefore, subsequent pregnancies should be delayed at least 18 months after removal of one kidney, both to permit complete compensatory hypertrophy of the remaining kidney and to assure complete recovery from the original disease for which the opposite kidney was removed. There is no limit to the number of pregnancies that may occur in women with a single kidney without subsequent impairment of the kidney. As many as five have been reported in one woman.

Congenital Polycystic Renal Disease.—Congenital polycystic renal disease may be encountered during pregnancy. Exacerbation of the pathological alterations already produced by this entity may be expected in many instances, although many women with early polycystic disease without hypertension or infection tolerate pregnancy well and may not even be aware of having the disease. However, in those already harboring pyelonephritis or infection within the renal cysts, the infection may be expected to increase as the result of the superimposed changes induced by the pregnancy itself. The same is true of hypertension, which is present in 75% of people with polycystic renal disease, even without the added influence of pregnancy. It is advisable, therefore, to advise women with moderately advanced polycystic renal disease against pregnancy and to interrupt an existing pregnancy in those in whom hypertension, infection, and impairment of renal function become more severe during pregnancy.

Renal Tuberculosis

Renal tuberculosis is adversely affected by pregnancy because of the impairment of drainage of the kidneys, with consequent back-pressure, as well as the increased incidence of superimposed pyogenic pyelonephritis. It is generally agreed that pregnancy should not be permitted in women with moderate or advanced renal tuberculosis, whether unilateral or bilateral, and that it should be interrupted if the disease is discovered after gestation begins, unless the pregnancy is sufficiently advanced to permit premature delivery of a viable fetus. However, because of the modern advances in the chemotherapy of renal tuberculosis, pregnant women with early renal tuberculosis without pyelographic deformity may be adequately treated and the disease controlled during pregnancy by specific chemotherapy. Therefore, pregnancy may be permitted in such cases or allowed to continue if already in progress, especially if the parents are anxious to have an heir and are prepared to take the risks involved. There is no appreciable risk of infection of the fetus in such cases.

Renal Cancer

Fortunately, renal cancer is rarely encountered during pregnancy, since the lowest incidence of neoplastic renal disease occurs in the group of women of childbearing age (15 to 40 years of age).[10] However, if renal carcinoma is discovered during pregnancy, the kidney obviously should be removed if the opposite kidney is competent and no metastases are demonstrable. Continuance of the pregnancy afterwards, in such cases, is an individual problem, depending on its importance to the family and the prognosis of the mother's disease.

Renal Calculi

Because of the stasis of urine in the kidneys of pregnant women and the increased incidence of infection, the number of renal calculi discovered during pregnancy would be expected to be greater than in nonpregnant women. Arnell and Getzoff[11] reported calculi in 1 of 852 pregnant women, which they considered to be twice the incidence in nonpregnant women of comparable age. In reviewing 20 cases they noted no maternal deaths but a fetal mortality rate of 15%, due to spontaneous abortion. Twelve of the 20 women were erroneously thought to have pyelonephritis and were at first treated for this condition. Folger,[1] who reviewed 352 cases of women with stones seen on the urologic service at Western Reserve, noted that 86 became symptomatic for the first time during pregnancy. The incidence of the onset of symptoms was the same in each of the three trimesters as well as in the puerperium. Pregnancy had to be interrupted in only five cases.

Silent stones, impacted in a peripheral portion of the collecting system of the kidney and not producing obstruction, are well tolerated during pregnancy and require only chemotherapy to control infection if present. Stones producing obstruction at the ureteropelvic junction or becoming impacted in the ureter present an emergency. The first consideration is relief of the obstruction by passage of a ureteral catheter into the kidney if possible. If a catheter can be passed, it should be left indwelling. After the symptoms have been controlled and renal function has been restored, definitive treatment can then be planned, depending on the size and position of the stone and the stage of the pregnancy. A stone within the ureter small enough to pass spontaneously may be given an opportunity to do so after an appropriate interval of drainage of the kidney and dilatation of the ureter by indwelling catheters. Those too large to pass either must be removed surgically during the pregnancy or, if the pregnancy is near term, continuous ureteral catheter drainage of the kidney should be employed until after delivery, when the stone can be removed either by open operation or by cystoscopic manipulation. In women whose stones are causing complete obstruction and in whom it is impossible to pass a ureteral catheter to the kidney, immediate surgical removal of the stone is mandatory, regardless of its size or position.

Operative Procedures During Pregnancy

If an elective operation on the upper urinary tract is being considered during pregnancy, several factors concerning the pregnancy itself become important in influencing the choice of time for operation. Transfer of the site of formation of estrogen and progesterone from the ovary to the placenta is probably gradual, being complete between the second and third months of gestation. By the fourth month the growing ovum entirely fills the uterine cavity, placental formation is complete, and the fetus is securely anchored to the uterine wall. The optimum time, therefore, for elective surgical procedures is after the 18th week. Before the 18th week the postoperative incidence of spontaneous abortion is high, for the reasons already mentioned. After the seventh month of gestation, delivery of a viable fetus can be expected, a fact that may sometimes influence the decision as to the choice of time for elective operation.

Preoperative preparation should include administration of the usual sedatives the night before, and also the morning of, operation. Patients with a history of threatened abortion require more careful preparation. In such cases a daily injection of 100 ml. of progesterone in oil should be administered to attempt to preserve the pregnancy. Administration of the hormone should be started one or two days before the contemplated operation if possible and continued as long as necessary postoperatively. However, in women who have had no difficulty up to the time of operation, hormone therapy is unnecessary. Several new drugs are now being investigated for use in threatened premature labor. A spinal anesthetic is preferable in most cases. Early ambulation is encouraged postoperatively, except in cases of threatened abortion.

Comment

Any woman with a known history of renal disease or hypertension who contemplates pregnancy should have a complete urologic examination before pregnancy is permitted. This should include careful examination of the urine for infection by smear and culture, renal function tests, and excretory urograms supplemented by retrograde pyelography when indicated. Since hypertension is one of the more common complications of pregnancy and although it is often associated with eclampsia or else is of the essential type, the possibility of an abnormality of the urinary tract should never be overlooked. Among the more important possibilities in addition to nephritis are unilateral atrophic pyelonephritis, polycystic renal disease, or bilateral obstructive hydronephrosis with pronounced impairment of renal function. The indications for therapeutic abortion in the presence of surgical renal disease must necessarily be individualized and the decision regarding interruption of the pregnancy considered in the light of the nature and extent of the renal disease, the general health of the patient, and, in borderline cases, the attitude of the patient and her husband regarding the importance of the anticipated child to them.

Summary

The urinary tract is one of the commonest sites of complications of pregnancy. The physiological changes occurring during pregnancy consist in dilatation of the upper two-thirds of the upper urinary tract, with impairment of drainage and resultant stasis of urine and back-pressure in the renal pelves. These changes are due to both hormonal and mechanical factors incident to pregnancy. In anticipation of these changes, any known preexisting surgical renal disease should be carefully evaluated by complete urologic study before pregnancy is permitted. The indications for therapeutic abortion in the presence of surgical renal disease discovered during pregnancy vary with the individual case. The decision must be based upon the nature and extent of the renal disease, the general health of the patient, and the risks that the parents are prepared to take to obtain an heir. Upper urinary tract surgery may be performed during pregnancy when necessary, without undue risk to the patient or the fetus, after careful selection of the optimum time for surgery and the proper preparation of the patient.

SURGICAL INJURIES OF THE URETER AND BLADDER

H. Haynes Baird, M.D.
and
Homer R. Justis, M.D., Charlotte, N. C.

• The ureters and bladder are liable to injury during surgical operations on other structures within or about the pelvis. How this can happen is shown in nine case histories, six of them involving hysterectomy, one a lumbar laminectomy, one a colpotomy with transection of the uterosacral ligaments, and one a cesarean section. The surgical treatment of the individual cases was successful, but more important are the means to be used in preventing such injuries. A catheter should be inserted during operations near a ureter, to aid in identifying and avoiding it. If it is ligated, severed, or otherwise injured, it should be repaired at the time. If there is danger of kinking, a soft ureteral catheter can be left in place four to six days postoperatively. Urinary symptoms developing after a pelvic operation require prompt and precise diagnosis. This is usually not difficult, once the possibility of this complication is borne in mind.

Accidental surgical injury to the ureter and bladder has always been frequent in association with pelvic surgery. Improved methods of anesthesia and replacement therapy have enabled the gynecologist to do more radical procedures, and, as a result, the incidence of ureteral and bladder injuries has increased. Also, improved diagnostic methods have brought about an increase in the total number of pelvic operations. The diagnosis of surgical injury to the ureter and the bladder is usually not difficult, once the possibility of this complication is borne in mind. Intravenous urograms followed by cystoscopy will make or exclude a diagnosis of ureteral injury. An opaque cystogram or injection of methylene blue into the bladder with the vagina packed is the usual method for determining the continuity of the bladder; cystoscopy may be used but usually is of less value. Injury to the ureters or bladder, when recognized at the time of surgery, should be repaired immediately.

No attempt will be made in this report to review the literature. The purpose of this report will be to briefly present a case illustrating each of the various types of ureteral and bladder injuries and a method of management, followed by suggested preventive measures in some types of injuries. The routine use of ureteral catheters, prior to a difficult hysterectomy, would eliminate most of the ureteral injuries.

Report of Cases

Case 1.—This 33-year-old woman with a left ureterovaginal fistula was seen three weeks after a hysterectomy. The ureteral injury was recognized at the time of surgery, and a ureteral catheter was left indwelling for two weeks; however, the site of the ureteral injury was not drained. After surgery, the patient had a constant vaginal drainage of urine and x-ray pictures demonstrated a fistula (fig. 1). A polyethylene tube (8 F.) was passed to the left kidney, meeting only mild resistance, and was left indwelling for 10 days. The vaginal drainage of urine ceased and the patient had an uneventful recovery, except for an episode of acute pyelonephritis caused by Aerobacter aerogenes. A urogram made eight months postoperatively showed a normal left urinary tract (fig. 2).

If a Penrose drain had been passed down to the site of the ureteral injury and brought out retroperitoneally through a stab wound, a ureterovaginal fistula probably would not have developed. Use of a ureteral catheter prior to hysterectomy would have prevented the injury.

Case 2.—This 45-year-old woman was seen because of a watery vaginal discharge for one month after an abdominal hysterectomy. Urologic examination revealed a ureterovaginal fistula, with obstruction to the intramural portion of the left ureter (fig. 3). At the time of operation, the left ureter was found to be ligated as it entered the bladder. The ureter above the site of ligation was dilated and tortuous. The ligated segment was sectioned and the proximal ureter spatulated, turned back in a cuff-like fashion, and reimplanted into the bladder through the original ureteral orifice. A pyelogram made one year later revealed normal renal function (fig. 4), and the cystogram showed no ureteral reflux.

Reimplantation of the ureter in the bladder as described above produces a ureteral stump in the bladder that prevents ureteral reflux. Again use of a ureteral catheter prior to hysterectomy would have prevented injury.

Case 3.—This 40-year-old woman was seen because of vaginal drainage of urine for three months after an abdominal hysterectomy for fibromyomas. Examination revealed a left ureterovaginal fistula and a severe cystitis due to A. aerogenes, with a bladder capacity of 3 oz. For two weeks many drugs were used without results, so drug sensitivity studies in vitro were done and revealed nitrofurantoin (Furadantin) to be the drug of choice. After one week's therapy with this drug, the bladder capacity returned to normal and the culture became negative. An exploratory operation on the lower part of the left ureter was then performed (by Dr. Dexter Amend); this revealed that the ureter ended in a fibrous mass proximal to the bladder (fig. 5). A segment of ureter 8 cm. long was missing, and a bladder flap after the technique of Ocherbold was used to bridge the defect. A polyethylene tube was left indwelling as a splint for 10 days postoperatively. A ureterogram and a cystogram made postoperatively (fig. 6 and 7) revealed no narrowing at the site of anastomosis or reflux of urine, respectively, four months later.

It has been stated that reflux follows this method of repair; such has not been our experience, as shown in the cystogram. Complete eradication of the severe long-standing cystitis due to A. aerogenes by the use of nitrofurantoin made the operation possible.

Case 4.—This 30-year-old male was seen four weeks after a lumbar laminectomy.[1] Immediately after the laminectomy, a mass developed in the left lower quadrant, which was incised and drained urine continuously. Urologic examination revealed a urinary fistula in the left lower quadrant and a grade 3 hydronephrosis on the left, with an occlusion of the left ureter at the junction of the upper two-thirds with the lower one-third (fig. 8). Exploration of the left ureter was carried out one month after

Summary

Most ureteral injuries can be avoided by the use of soft ureteral catheters during difficult pelvic surgery. If a ureteral injury is discovered during surgery, it should be repaired immediately. A ligature around the ureter found after surgery should be removed as soon as the patient's general condition permits. A completely severed ureter should be repaired by using interrupted vertical mattress sutures so as to evert the two cut ends. Ureteral reflux has not occurred after reimplantation of the ureter into the bladder when a cuff of the ureter projects into the bladder.

Bladder injuries when discovered during operation should be repaired then, but, if discovered later, the repair should be delayed for four to eight weeks.

1012 Kings Dr. (Dr. Baird).

PATHOLOGICAL LESIONS OF THE FEMALE URETHRA

Laman A. Gray, M.D.
and
William B. Pingelton, M.D., Louisville, Ky.

• *Abnormalities and diseases of the female urethra include the caruncle, diverticula, cysts, carcinoma, urethritis, trigonitis, venereal infections, and the unusual conditions of polyps and congenital valves. Over a 20-year period of observations, it was found that prolapse of the posterior margin of the mucosa at the urethral meatus was extremely common after the menopause, although it may also occur in younger women and children. Of 108 pathological specimens of the female urethra, 71 were urethral caruncles. The common caruncle rarely is malignant and, unless symptomatic, often requires no treatment. Other treatment for pathological conditions of the female urethra depends not only on the lesions observed but, occasionally, on related syndromes such as anxieties and allergies.*

The short tubular structure representing the female urethra is subject to a surprising variety of abnormalities, because of its position, delicate membranes, attached ducts and glands, developmental variations, occasional venereal diseases, changes in natural hormones, and even the stress and strain of life. Study of specimens from the female urethra, obtained over a period of 20 years in the Louisville General Hospital and in private practice, has led us to summarize and describe the following lesions.

Venereal Diseases

The urethral meatus of the female may be affected by the venereal diseases, including the temporary chancre of syphilis, acute or chronic gonorrheal infection in Skene's ducts, probably the chancroid and granuloma inguinale, and particularly the ulcerative destructive lesions of venereal lymphogranuloma. Formerly, it was thought that all infections of Skene's ducts were gonorrheal in origin. While the gonococcus thrives in that environment and must be considered as an etiological agent, Trichomonas vaginalis is considered to be the more common offender today. The Trichomonas infection produces minute red dots around the meatus (and vestibule also) and may produce a caruncle of reddened, edematous appearance and the chronic white discharge that may be milked from the urethra over a period of years. Shelanski and Savitz[1] in 1939 pointed out the relationship of T. vaginalis infestation to Bartholin's gland (with secondary invaders) and infections of Skene's ducts; more recently, in 1955, Kean[2] has emphasized the frequent finding of T. vaginalis in the urethra of women. Infection from this obstinate organism rarely requires direct manipulation of the urethra, caruncle, or Skene's ducts but does necessitate persistent and prolonged antitrichomonacidal treatment to the vagina. Apparently T. vaginalis infections may or may not be acquired by sexual intercourse; they are commonly nonvenereal.

The urethral syndrome of venereal lymphogranuloma, described by Gray[3] in 1936, apparently begins as a chronic urethritis, with or without intraurethral ulceration, which may remain extremely chronic and indolent or may proceed to urethral stricture or to ulcerative destruction of the urethra; the ulceration may extend beneath the clitoris and labia or about the introitus and deeply to the sides of the rectum; and elephantiasis vulvae may be associated. This disease, diagnosed by exclusion and by the intradermal Frei test, producing severe chronic inflammation with no specific microscopic characteristics, is seen where venereal disease is common, is extraordinarily rare in a usual practice, and is apparently decreasing in incidence. The United States Public Health Service indicates that 2,603 cases of venereal lymphogranuloma were reported in the United States in 1946, but only 875 cases in 1955. The incidence of all venereal diseases has declined over these years.

Verruca acuminata (condyloma acuminatum), or common wart about the genitalia, is attracted by the urethral meatus. In 108 specimens of lesions of the urethra, reported in this paper, 8 showed the benign squamous cell proliferation on papillary folds characteristic of this virus disease. The extreme proliferation of squamous epithelium and numerous mitoses at times require consideration to assure the benign

character of the lesion. This so-called venereal wart may be transmitted by sexual intercourse, but it may be acquired without such a social contact. These were treated by excision, administration of podophyllin, and probably best by fulguration.

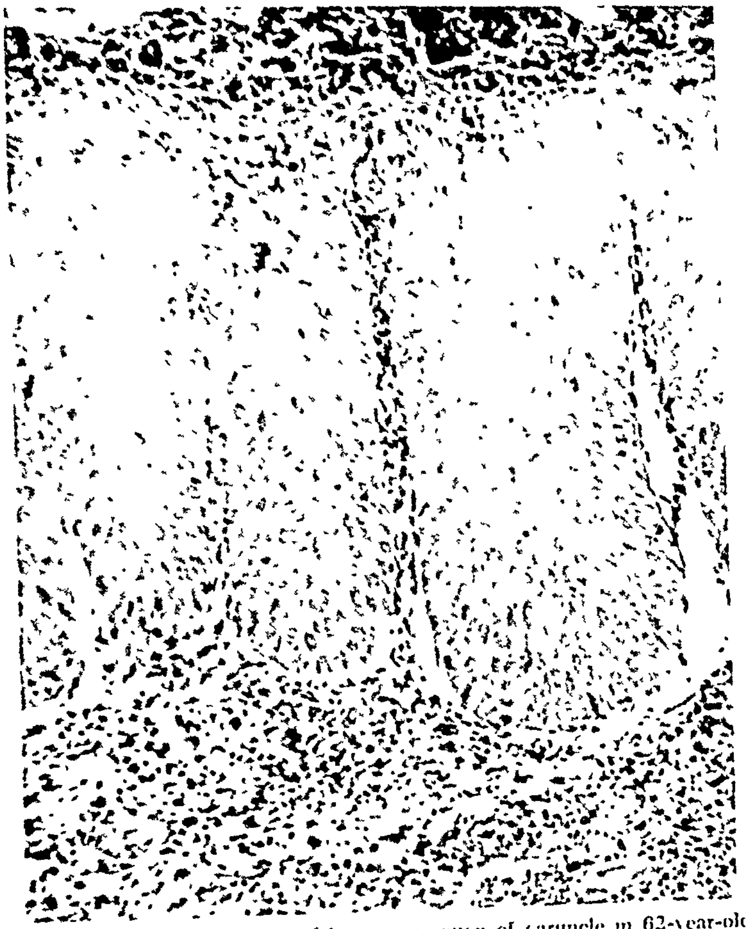

Fig. 1.—Photomicrograph of biopsy specimen of caruncle in 62-year-old woman before treatment with estrogen cream.

Urethral Caruncle

Prolapse of the posterior margin of the mucosa at the urethral meatus is extremely common after the menopause, but may occur in younger women, including children. Small caruncles commonly cause no symptoms; large ones may produce few complaints. It is not a tumor. Slight burning discomfort, soreness, pain on urination, and dyspareunia require treatment. Occasionally the pain is severe. Infections of the urethral meatus and Skene's ducts may be causal factors. Absence of estrogenic hormone, after the menopause, causes atrophy of the urethral and vaginal epithelium, with susceptibility to irritation, inflammation, and infection. Perhaps the lack of hormone also loosens the lining mucosa.

After studying 91 specimens of benign lesions from the urethral meatus, we have considered that 71 are true caruncles, 12 are granulomas, and 8 are verruca acuminata (mentioned above). The true caruncles have been divided into three groups by us, according to their surface epithelium, which suggests the point of origin. Others have separated the angiomatous type, but the dilated and proliferated vessels are likely related to the prolapse, edema, and inflammation. The granulomatous type of caruncle seems separate, being a primary infection, in contrast to accented prolapse of the mucosa in the true caruncle.

Group 1.—Sixteen of the caruncles had a surface completely covered with stratified squamous epithelium. Of these, 10 contained no glands and 6 contained gland spaces lined by transitional epithelium. Thirteen of these specimens were from postmenopausal women. Inflammation associated with proliferation of small vessels varied from slight to severe.

Group 2.—In 28 specimens the surface of the caruncle was covered by stratified squamous and by transitional epithelium. In 20 of these, there were no glands; 8 contained glands lined by transitional epithelium; and 9 were from postmenopausal women. Four patients were quite young (aged 9, 11, 14, and 19).

Group 3.—In 27 specimens, the caruncle was covered entirely by transitional epithelium and all contained transitional glands. The degree of inflammation varied. In two patients, aged 38 and 17, the caruncles showed marked mucous secretion of the glands; the specimen from the former case originally was considered to represent a low-grade adenocarcinoma, was excised locally, recurred as a slight caruncle five years later, and showed a clearer transitional epithelial gland pattern at the last biopsy. Of this third group of 27, one was from a patient 3 years old and one from a 10-year-old patient, but 20 were from postmenopausal patients.

Of the entire 71 caruncles, 9 showed cellular atypia, involving the transitional glands in five cases and the prolonged rete pegs of the squamous epithelium in four, the latter attributed to inflammation. The transitional cell changes are to be carefully distinguished from carcinoma, as an error may be made in each direction. As a rule the carcinomatous change must be very clear. At least 13 patients with caruncles had no complaints before excision or fulguration, but some developed complaints subsequently.

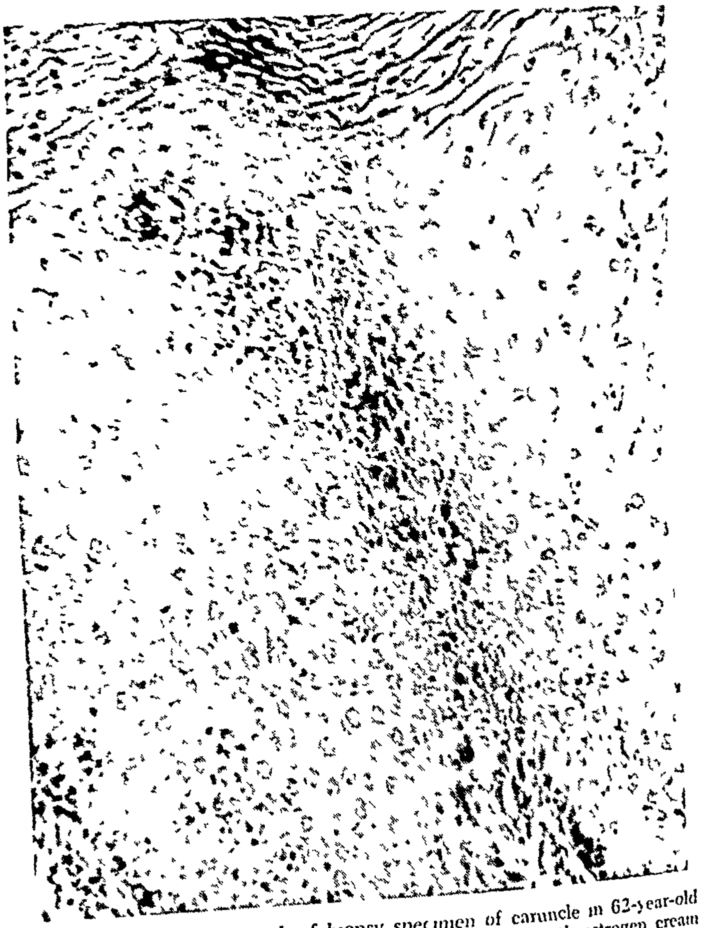

Fig. 2.—Photomicrograph of biopsy specimen of caruncle in 62-year-old woman (see fig. 1) after 21 days of local treatment with estrogen cream (Estrone sulfate).

In 12 other cases the diagnosis was considered granuloma, because of severe, nonspecific, inflammatory reaction. Three showed no surface epithelium, and nine specimens were partially covered with stratified squamous epithelium. The origin here seemed a definite infection, possibly venereal (average age of patients, 39 years). Perhaps several of the previous cases considered caruncles should be included with the granulomas, as some had marked inflammation.

Biopsy has been performed in only a small percentage of caruncles in our care of patients. The majority had no treatment. In the case of a large or angry lesion, one showing any brittleness, hardness, or surrounding induration, one bleeding easily, or one requiring general anesthesia and fulguration, biopsy was always performed before treatment. Often satisfactory improvement followed treatment of T. vaginalis infection, or the use of oral or local estrogenic therapy in older women (fig. 1 and 2). Because of the great frequency of the urethral caruncle, small or large, and the rarity of carcinoma of the urethra, we believe that the ordinary caruncle represents very slight risk to the patient and that treatment is primarily indicated to relieve symptoms.

Prolapse of the urethra, a circular prolapse in contrast to the more common posterior prolapse of the caruncle, was observed in two cases. One was in a child 3 years of age, and one was in a postmenopausal patient. They were treated by ligation around a catheter and circular excision, with resuture around the meatus.

Urethral Diverticulum

Urethral diverticula may be of acquired or congenital origin (Nel[4]). The acquired sac develops after perforation or local dilatation, usually after infection, abscess, and rupture of a paraurethral gland. The trauma of parturition is a factor in some cases. The congenital types arise from Gartner's ducts, faulty union of primal folds, cell rests, Müllerian remnant cysts, or congenital dilatation of paraurethral ducts. The diverticulum may or may not have the muscular layers of the urethra about it and may be lined with squamous, columnar, cuboidal, transitional epithelium or by granulation tissue only.

In some there are no symptoms. In others there may be pain in the lower abdomen, suprapubic, or perineal areas; pressure, weight, or pain in the vagina; pain radiating up into the pelvis when sitting; burning discomfort, severe dysuria, severe frequency; recurrent cystitis; or dribbling after voiding. Pain at the end of urination and dyspareunia are frequent complaints. The diverticulum may remain undiscovered even after long investigation and treatment. The soft sac often is not palpated, but milking the urethra during vaginal examination may produce purulent fluid and prompt the diagnosis. Demonstration of the orifice at cystoscopy, whether by the direct vision endoscope or the panendoscope, may be difficult. Filling the sac for radiographic visualization may be unsatisfactory.

Complications include infection with abscess, which may require incision and drainage. Calculi form occasionally. Three cases of malignancy—an epithelioma, a mucous-secreting adenocarcinoma, and a transitional cell carcinoma—have been reported in three studies (Walters and Thiessen,[5] Hamilton and Leach,[6] and Wishard and Nourse[7]).

Diverticula should be excised because of proximity of the infected sac to the bladder and for relief of symptoms. Various methods have been suggested, including incising the meatus down the urethra into the sac, with subsequent excision and repair (Edwards and Beebe[8]). Meticulous excision of the sac itself, with closure in layers, using 0000 absorbable surgical sutures in the mucosa, retention catheter for 10 days, and antibiotic therapy gave good results in our hands (fig. 3).

Thirteen cases of urethral diverticula were studied in this series. Four specimens were lined by stratified squamous epithelium, two by transitional epithelium, two by a single layer of columnar epithelium, and five by granulation tissue. Two of the latter showed small tubular glands with columnar cells extending into the wall of the diverticulum. One resembled carcinoma, but the apparent invasion was attributed to the inflammation and the patient was well after five years.

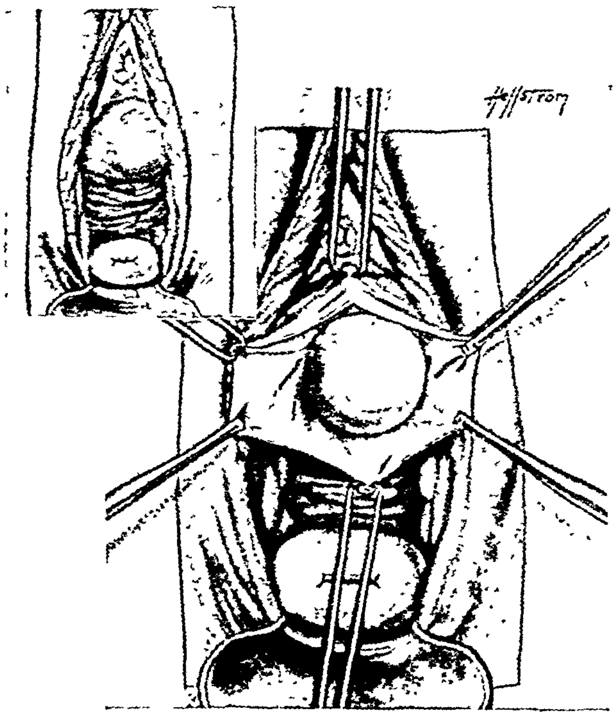

Fig. 3 —Excision of suburethral diverticulum

Postoperative complications may include fistula, stricture, or recurrence. In this series of 13 cases, one patient developed a fistula that healed after four months, one had severe postoperative bleeding from the operative site, and one developed a recurrent diverticulum. This was cured after reexcision.

Suburethral Cysts

Suburethral cysts are less common than diverticula. They may arise from a diverticulum with sealed neck, but more often arise from Müllerian duct remnants or detached urethral glands. Occasionally they cause severe pain, perhaps due to trauma and rapid enlargement, but usually they are asymptomatic. These cysts may extend up around the urethra on one side or the other. A similar lesion is the subvesical cyst, which may extend far up alongside the cervix and be removed with difficulty. Two patients with excised cysts had a lining epithelium of flattened transitional epithelium, one with transitional glands in the wall. There was no inflammation. Excision should be performed carefully but should be complete.

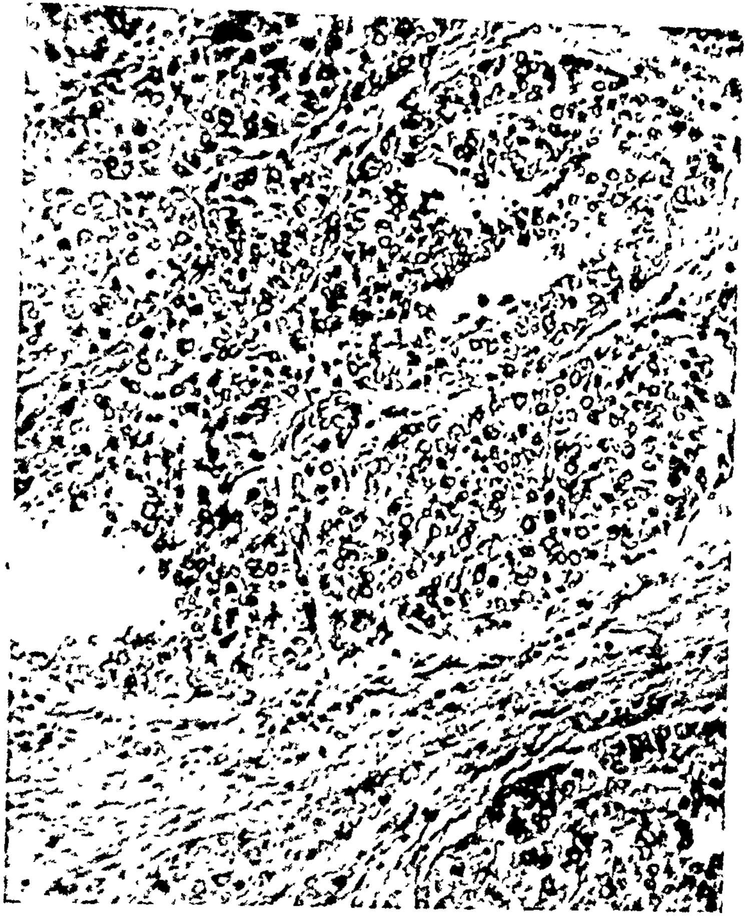

Fig. 4 (case 1).—Photomicrograph of transitional cell carcinoma, rapidly growing.

Carcinoma of the Urethra

Some 600 cases of carcinoma of the female urethra have been reported to date. Symptoms include hematuria, severe dysuria, and swelling. Approximately half the patients have given a history of chronic irritation or of caruncle treated previously. The gross appearance is that of a firm, rolled-out granular growth, an indurated ulcer, or, more rarely, the entire urethra may be encircled with infiltrating tumor. Ritter[9] described four types: exophytic squamous cell type, endophytic squamous cell type, adenocarcinoma (much less common), and rare miscellaneous tumors, including sarcoma and melanoma. Origin from transitional epithelium with variable degree of proliferation probably is more frequent than origin from squamous epithelium near the tip of the urethra. Metastases to inguinal nodes have been common and apparently occur early. Most clinicians advise operative removal with or without postoperative irradiation, but results have been discouraging. Radical excision has been tried recently. Brack and Farber[10] reported 10 cases and recommended relatively heavy radium and x-ray therapy, with consideration of later excision. Removal of the inguinal nodes is advisable. Most authors agree that the treatment of choice is surgical excision, but it may be that rapidly growing, anaplastic tumors should have irradiation therapy. We have had only two cases of cancer in this series. One was in the Louisville General Hospital, and one in private practice.

Case 1.—A patient, aged 49, developed frequency, urgency, nocturia, intense constant pain in the urethra, and difficulty in starting urination in September, 1951. On Oct. 31, 1951, a severe urethral stricture was found. On Dec. 5, 1951, the meatus was everted, with rolled-out, firm edges; the entire urethra was indurated and pipe-like; and the vesical neck was irregular with ragged tissue on the inner margin. Biopsy showed infiltrating carcinoma (fig. 4). Ureteral transplantation to the sigmoid was performed. On Jan. 8, 1952, the urethral tumor was fixed to the symphysis, and there was extension beneath the bladder on the left. On Jan. 17, 1952, the bladder, uterus, vagina, and symphysis pubis were removed (by Dr. R. A. Griswold). A right lateral mass in the obturator foramen could not be excised; biopsy showed metastatic carcinoma. The patient died March 12, 1952, after a complicated course and while receiving x-ray therapy. This patient had a very rapidly growing, infiltrating transitional cell carcinoma made up of relatively small cells, with numerous mitoses. The tumor developed from a urethral stricture in two months to involve the entire urethra and to invade local structures and the symphysis pubis. Apparently within this short duration it had become inoperable.

Case 2.—This 75-year-old woman complained of a severe bearing-down pain, bleeding, incontinence of urine, and marked sensitivity of vagina and vulva for three months. Examination showed ulcerative destruction of the anterior urethra, with extremely tender nodular tumor, interpreted on biopsy as a papillary transitional cell carcinoma, grade 2 (fig. 5). The tumor, clitoris, and bladder neck were resected on June 5, 1953, closing the bladder neck around a Foley catheter. (A conservative operation was elected because of the age of the patient.) Pain was relieved, but the area was not satisfactorily dry. On Jan. 8, 1954, after slow local recurrence and increasing pain, anterior exenteration was performed, removing the bladder, uterus, and vagina, and transplanting the ureters to the sigmoid. The postoperative course was not difficult, but 24 days later the patient died of a

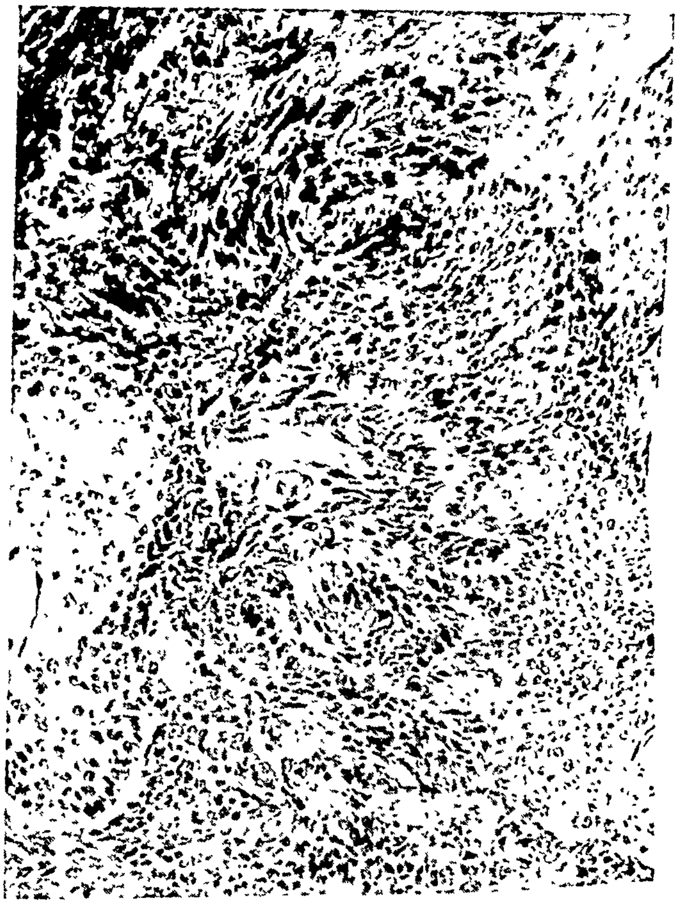

Fig. 5 (case 2).—Photomicrograph of transitional cell carcinoma, relatively slowly growing.

cerebral attack at home. Postmortem examination, limited to the abdomen, showed no infection, no residual tumor, and satisfactory healing of the ureteral transplants, without stricture.

It seems that a slowly growing tumor with a long history may be better treated by wide excision alone but that a rapidly growing tumor may be better treated by intensive irradiation and subsequent excision if deemed advisable. While malignancy of the urethra is not common, early diagnosis is important.

Unusual Lesions of the Urethra

Everett and Brack[11] recently described unusual lesions of the female urethra, discovered only by painstaking study with the panendoscope. These included congenital valves in children, minute urethral diverticula, and urethral polyps. The symptoms were recurring cystitis, intermittent hematuria, dysuria, and eneuresis. Schloss[12] described caruncles of the posterior urethra and bladder neck that produced symptoms of "irritable bladder" and "chronic urethritis." These were treated by resection.

Chronic Urethritis and Trigonitis in Women ✓

Urinary frequency, burning, and pain, in the absence of pyuria and with negative cultures, long have been attributed to chronic urethritis and trigonitis. Various treatments have included the application of dilute solutions of silver nitrate, fulguration of the bladder neck and urethra, resection of the bladder neck, dilatation of the ureters, and, most popular of all, repeated dilatation of the urethra. Numerous antiseptics have been used locally. Allergic phenomena have been implicated as a common cause by some authors (Powell and Powell[13]).

The syndrome occurs mainly in those with great nervous tension and severe anxieties. It is remarkable how often a single severe emotional jolt seems to have precipitated these difficulties. Resolving a personal problem (unfortunately frequently impossible), reassurance, and use of tranquilizing drugs seem of more value than local urologic treatments. Our success has been limited after dilatations and local therapy.

Summary and Conclusions

Venereal diseases of the urethra in females include gonorrhea and venereal lymphogranuloma. The incidence of both has greatly decreased. Chronic infection in Skene's ducts more commonly is due to Trichomonas vaginalis. The latter may or may not be transmitted by sexual contact. Verrucae acuminatae (condylomata acuminata) are not uncommon (occurring in eight cases in this study).

Study of 108 pathological specimens of lesions of the female urethra revealed the following findings: 71 urethral caruncles had a surface of squamous epithelium in 16, of combined squamous and transitional epithelium in 28, and of transitional epithelium alone in 27. Forty-two patients had passed the menopause. Lack of estrogenic hormone seems a factor in many of these cases, and the lesion tends to regress after application of estrogenic creams. In younger women, infection, including T. vaginalis infection, is a factor and may necessitate prolonged treatment of the vaginitis. The common caruncle rarely is malignant. Usually it is asymptomatic, and often no treatment is indicated.

Twelve specimens showed granulomas, related to infection; three of these had no surface epithelium and nine had partial covering of squamous epithelium. Eight specimens showed verruca acuminata, the infectious wart, usually treated by fulguration. In 13 specimens showing suburethral diverticula, there was a lining of squamous epithelium in four, transitional epithelium in two, columnar epithelium in two, and inflammatory tissue alone in five. Excision was followed by postoperative hemorrhage in one case, a temporary fistula that healed spontaneously in one, and a recurrent diverticulum in one, which was cured by reexcision.

Two suburethral cysts, lined by transitional epithelium, were excised without mishap. Carcinoma of the urethra was seen in two patients. One cancer grew very rapidly, one more slowly. Rapidity of growth may be a determining factor in the choice of irradiation or excision.

Chronic urethritis and trigonitis in women commonly appear to have a psychogenic origin. After thorough investigation, these conditions are treated better by tranquilizing drugs and approach to the emotional causal factors.

Thrombocytopenic Purpura.—Immune thrombocytopenic purpura due to Fuadin [antimony compound used in the treatment of parasitic infections] occurred on 2 occasions when the drug was given. Administration of plasma from this patient to a recipient who also received Fuadin produced thrombocytopenia without purpura. It is postulated that thrombocytopenic purpura . . . was due to the occurrence of a drug-antibody complex capable of destroying or agglutinating platelets and depressing megakaryocyte activity.—J. V. Rivera, H. F. Rodriguez, and E. Perez-Santiago, *The American Journal of Tropical Medicine and Hygiene*, September, 1956.

URINARY INCONTINENCE

Andrew A. Marchetti, M.D., Washington, D. C.

• *Of 132 patients who had a simple vesicourethral suspension for urinary stress incontinence, 84% could be considered completely cured. Urinary stress incontinence, considered the most commonly acquired type of female incontinence, is generally the result of birth trauma or a sequel to some form of vaginal operation. While the operative procedure described may be considered relatively simple and safe, its effectiveness depends on careful patient selectivity based on extremely detailed diagnostic procedures.*

The complaint of urinary incontinence in the female is not an infrequent one. It is a distressing complaint, especially since it frequently afflicts women who are otherwise in good general physical condition. Interest in the nature and varieties of urinary incontinence as well as in the approaches to its correction has been widespread and abundant. In recent years, for instance, much has been written about, and many operations have been devised or modified for, the correction of urinary stress incontinence. The operation, however, is yet to be found for the unfailing cure of this complaint.

Without entering into a complete discussion of the various causes of incontinence, one must be reminded that there are neurological, urologic, and psychosomatic sources as well as obstetric and gynecologic ones. Furthermore, urinary incontinence may be congenital, though more often it is acquired. This paper will be confined to the most frequently acquired type of female incontinence, that is, urinary stress incontinence. It is generally agreed that this type of loss of urinary control generally is the result of birth trauma and occasionally is a sequel to some form of vaginal operation.

Diagnosis

The diagnosis of female urinary stress incontinence is not always easy. Aside from a very searching history and an adequate general physical examination (to clude a thorough vaginal examination and a simple eurological examination), complete urinalysis, endoscopy, cystoscopy, cystometry, urethrocystography, evaluation of renal function, and any other test that seems indicated should be regularly used to determine whether one is dealing with stress incontinence. Stress incontinence is most often confused with urge incontinence. Where the two conditions coexist, it becomes obvious that the urge incontinence is to be treated before one may proceed with the correction of the other. In my experience, I have learned that a complete urinalysis, including a urine culture and endocystoscopy, is a mandatory procedure in diagnostic examination.

Finally, the urethral elevation test or so-called stress test is to be done, not only to help confirm the diagnosis of stress incontinence but also to aid in predicting the result that might be expected from a particular type of operation. Briefly, the stress test consists of filling the bladder with 250 cc. of saline solution and then having the patient cough or sneeze in the lithotomy and standing positions. If the patient really has loss of urinary control, this test will demonstrate it. After the incontinence has been confirmed, the bladder is refilled to the same capacity if necessary. Then, with two digits in the vagina, the urethra and neck of the bladder are elevated and supported behind the symphysis pubis, simulating the objective of simple vesicourethral suspension. Care must be exercised not to obstruct the urethral lumen during this maneuver by placing the fingers lateral to the urethra. Under these circumstances, the patient is asked to cough or sneeze again in the lithotomy and sometimes in the standing position, and, if she manifests no loss of urine, a probable successful outcome from the operation is predicted.

Technique

A review of the different types of operations that have been described for the correction of stress incontinence will be omitted in this presentation. However, a description of the operation of simple vesicourethral suspension published by Marshall, Krantz, and me[1] in 1949 bears repetition, since a few minor modifications have changed slightly the original technique. After the patient has been prepared for operation, a 24-F. Foley catheter with a 30-cc. balloon is inserted into the bladder and the bag inflated. The operation is usually done with the patient under general anesthesia. The patient is then placed in a slightly inclined Trendelenburg position. A suprapubic incision is made to expose the space of Retzius widely. A vertical or Pfannenstiel incision may be made through the skin. The bladder and urethra may be separated from the posterior surface of the pubis and rectus muscles down to about 1 cm. of the position of the external urethral meatus by use of light pressure, applied with a sponge on a ring forceps, on the top of the bladder and the urethra.

It should be pointed out that the suspensory attachments between these structures are found to be very delicate in the female, when compared to the strong puboprostatic ligaments of the normal male. Formerly an assistant's fingers were inserted in the vagina, to aid the operator to palpate the catheter and the balloon and thus properly identify the position of the urethra and the bladder neck. This part of the technique no longer is found to be necessary. It is recommended, however, for those who are doing the procedure the first few times. One should be cautioned to be gentle when the perivesical and periurethral tissues are pushed aside by blunt dissection, since these tissues contain many blood vessels, especially veins, and as a result, if gentleness and some care are not exercised, one may encounter a considerable amount of bleeding and oozing. Should this occur, it should be controlled by pressure.

From the Department of Obstetrics and Gynecology, Georgetown University School of Medicine.

Read before the Joint Meeting of the Section on Obstetrics and Gynecology and the Section on Urology at the 105th Annual Meeting of the American Medical Association, Chicago, June 14, 1956.

After adequate exposure of the bladder and urethra, three sutures of 1 chromic absorbable surgical suture are placed equidistant from each other on either side of the urethra. With each one of these sutures a round needle is used to carry the suture deeply into the vaginal wall adjacent to the urethra, but not to include the lateral wall of the urethra, as was indicated in the original description of the procedure. A double bite in the vaginal wall may be taken to insure a secure hold. Then the long end of each one of these sutures may be carried by a round cutting needle and secured to the periosteum of the pubis, and whenever feasible to the cartilage of the symphysis. An effort should be made to have the position of these sutures correspond as much as possible, in order to avoid distortion and inordinate tension. Before these sutures are tied, another suture should be placed in the midline at the juncture of the urethra and the bladder neck in the same manner that the previous ones were placed. After this, they are properly identified and tied. This portion of the operation brings the urethra and bladder in close apposition to the posterior surface of the symphysis pubis and partially obliterates the space of Retzius.

Additional sutures are now placed at points lateral to the urethra where the vaginal wall is found sagging. Usually one such suture on each side suffices. More sutures are then placed in the musculature of the lateral and lower portions of the bladder and secured to the posterior surfaces of the rectus muscles. This further pulls the bladder anteriorly into the space of Retzius. The number of sutures to be used in this part of the operation is governed by the needs in each individual case. A small rubber drain is placed laterally on each side of the operative site and the abdominal wound is closed in a routine manner, with the ends of the drains brought out through the lower end of the incision. Should the lumen of the bladder or of the urethra have been accidentally penetrated during the course of the procedure, the operative field is better protected against urinary leakage by the use of the drains in the space of Retzius and by the use of chromic absorbable surgical suture.

After the completion of the operation, the 30-cc. Foley catheter is replaced by a 5-cc. one, and a gauze pack is inserted in the vagina before the patient is removed from the operating table. The pack is removed from the vagina on the following day. The suprapubic drains are usually taken out on the second postoperative day and the catheter on the fourth day. In most instances, the patient voids spontaneously after removal of the catheter. She is usually discharged from the hospital on the eighth or ninth postoperative day.

Advantages and Indications

Although it is fully realized that this technique is not the answer to all cases of urinary stress incontinence, some of its chief advantages should be mentioned. The approach is simple and the technique may be considered relatively easy. The field of operation is unobstructed and sufficiently wide to permit a full view of the superior and lateral aspects of the urethra and the neck and base of the bladder. The best indication for this procedure, in our experience, is in cases of recurrent stress incontinence where repeated standard vaginal operations have failed and where, as a result of scarring and distortion, further approach through the vaginal route is no longer feasible. The procedure may be primarily elected in elderly women in whom a major vaginal operation is not advisable but in whom the restoration of urinary control is paramount for their comfort and well-being. It may be further elected in women, particularly those of childbearing age, who complain solely of stress incontinence and who appear to have no need for vaginal plastic surgery.

Clinical Data

The clinical data that will be briefly presented are gleaned from the combined experience of myself, Marshall, and Shultis [2] with 132 patients who had a simple vesicourethral suspension for urinary stress incontinence.

Age Incidence.—The average age among these patients was 54 years. The youngest patient was 21 years of age and the oldest was 76 years.

Classification.—After the degree of incontinence was evaluated in each case, 55 cases were classified as severe or as those in which patients constantly had loss of control, 64 as moderate, and 13 as mild.

History of Previous Operations.—There were 65 patients who had had previous vaginal operations. Fifteen of these had had a total of 35 operations on the urethra or bladder for loss of urinary control. In the remainder, the operation was elected as a primary procedure. The operation was combined with total abdominal hysterectomy on six occasions and with a posterior repair on nine occasions.

Vesicourethral Suspension and Pregnancy.—In this series, four women were delivered of five babies after having had a vesicourethral suspension. One had two spontaneous deliveries and each of two had one after the operation. The fourth patient had a cesarean section, since her previous operative history included not only a vesicourethral suspension for incontinence but also a successful procedure for the closure of a vesicovaginal fistula. To date, there has been no recurrence of incontinence among these four patients after their pregnancies.

Results.—Results were classified as successes or failures. In other words, the result for any patient who was not totally relieved of incontinence, even though there might have been some improvement, was counted as a failure. The follow-up on these cases now has extended over 10 years, and only 4 of the 132 patients have been lost to follow-up over this period. The rate of immediate successes in our survey reached 88.6%. Among these there were six patients who had late recurrences of their incontinence, which reduces the over-all incidence of successful outcomes to 84%. It ought to be stated that some of the earlier patients were ill-chosen and today would not be considered desirable candidates for the operation.

Complications.—In our experience, the complications encountered until now cannot be considered serious. In approximately 75% of the cases, a transient hematuria lasting from 12 to 24 hours was noted. In four instances, periostitis pubis complicated the postoperative course, and all of these patients promptly responded to antibiotic therapy. Repeated catheterizations had to be resorted to in four patients for 7, 12, 15, and 17 days respectively. Cellulitis in the region of the incision was encountered twice. Hematomas complicated the picture on four occasions and one of these was associated with a dehiscence of the wound. In one case where nonabsorbable suture material was used, a urinary fistula ensued, which spontaneously healed by the end of three weeks. One patient developed an incisional hernia postoperatively, and this was subsequently repaired.

Morbidity.—There was one death among this group of patients. It occurred in a woman 75 years of age who died on the second postoperative day from a pulmonary embolism.

Summary

The complaint of urinary stress incontinence in the female is not rare, and the diagnosis at times is not easy. Among many of the diagnostic procedures that may be used, a complete urinalysis; endocystoscopy, including urine culture; and the urethral elevation test are mandatory in each case before operative correction may be considered. Although simple vesicourethral suspension is not a cure-all, it has earned a creditable place among many other operations that have been devised for the correction of stress incontinence. The technique is not difficult, and it is a relatively safe procedure to undertake. It is indicated best in cases where repeated vaginal operations have failed.

In over 10 years of experience with simple vesicourethral suspension, the complications have not been serious. Unless urinary control was totally restored, the result in a patient was considered a failure; it was never made worse by the operation. Finally, an overall incidence of success of 84% was achieved. As experience grows and as one becomes more selective in the choice of candidates for the operation, I feel confident that a still higher rate of success will be attained.

COMBINATION THERAPY OF RETINOBLASTOMA WITH TRIETHYLENE MELAMINE AND RADIOTHERAPY

George A. Hyman, M.D.
and
Algernon B. Reese, M.D., New York

• *Retinoblastoma in 50 children between the ages of 2 months and 7 years was treated by a combination of radiotherapy and triethylene melamine. This series included only cases in which the disease had not extended beyond the local area. The usual dosage of radiation was 2,400 r in air through each of two portals. The drug was given by mouth originally and later by intramuscular injection, or by instillation into the internal carotid artery, the dosage being adjusted according to the weight and hematological response of the patient. The tumor was arrested and vision preserved, as judged from subsequent observation over a period of at least six months, in 12 out of 33 children who received the drug by mouth. Arrest of tumor growth and retention of useful vision was achieved in seven of eight children who received the drug intramuscularly. The intracarotid route was used in nine far advanced cases that had been classified as "almost hopeless"; in this group the tumor was arrested and useful vision preserved in two cases. The results have been better than those obtained in the past in comparable series with radiotherapy alone. Therapeutic doses of triethylene melamine produce hematological depression, and complete blood cell and platelet counts are a necessary and useful guide to the dosage and prevention of potentially severe toxic reaction in these cases. Given by mouth, the drug produced the maximum leukopenia in about nine days; given intramuscularly, it required about half that time. The latter route is definitely preferred.*

Retinoblastoma is a uniformly fatal, progressive disease appearing most frequently in children between the ages of 6 and 24 months. The untreated tumor usually advances by direct extension along the optic nerve into the central nervous system or spreads via the blood stream to skin, skeleton, and eventually to other organs. Recently the therapy of this neoplasm has been undergoing modification and improvement, especially in regard to the techniques of radiotherapy.[1] However, the appearance in a number of instances of late hemorrhagic retinitis and the percentage of failures requiring eventual enucleation have led to the consideration of other modes of therapy.

The experimental work of Gillette and Bodenstein[2] has indicated that nitrogen mustard might have a specific effect on the proliferating retinal cells. In 1953 Woods and Kupfer[3] first reported the combination of nitrogen mustard and radiotherapy in the treatment of a patient with this disease. An attempt to evaluate the possible additive or synergistic effect of nitrogen mustard analogues and radiotherapy has been in progress since 1953 as a joint project of the departments of ophthalmology, radiotherapy, and medicine of the Columbia-Presbyterian Medical Center. The results of the study will be reported below.

Methods and Patient Material

Fifty-five patients with retinoblastoma have been treated since January, 1953, with combined radiotherapy and triethylene melamine. Of these, 50 cases will be reported, since in these therapy has been completed for at least six months to three years. With repeated examinations by an experienced ophthalmologist, the eventual outcome of therapy for this tumor is generally predictable in less than five years after completion of treatment, because of calcification and certain other characteristics noted when this tumor becomes arrested.[4]

The patients selected were those in whom adequate preliminary study disclosed that the disease had not extended beyond the local area. Adequate preliminary study included chest, skull, and orbital x-rays and skeletal x-ray survey, urinalysis, and a complete blood cell and platelet count, in addition to a careful history and physical examination. The children were generally from 6 months to 2 years of age, with the range being from 2 months to 7 years. Triethylene melamine was selected originally because it was available in a form for oral administration, in view of the difficulty of intravenous administration of nitrogen mustard in small children.

The triethylene melamine was given orally with 2 gm. of sodium bicarbonate with the patient in the fasting state, according to the method of Gellhorn,[5] and 24 hours later ocular radiotherapy was instituted. The second dose of triethylene melamine usually coincided with the last radiotherapy treatment, and the third dose was given after radiotherapy was completed but within the time period of its continued direct effect. The optimal timing of these two agents is a matter of further study at present. The dose selected at first was based on previous experience with adults and was modified subsequently according to the hematological response of the patient. At present the form for oral administration has been discarded because emesis and irregularity of absorption interfere with accuracy of dosage, especially when leukopenia or thrombopenia does not develop.

Currently, a new preparation of triethylene melamine for parenteral administration is being used. Eight patients have been treated with intramuscular injections and nine with intra-arterial injections made directly into the internal carotid artery. The preparation of triethylene melamine for intramuscular administration was given in a dosage of about 0.1 mg. per kilogram, with the patient in the fasting state, by the following routine: A 2-cc. sterile tuberculin syringe was used throughout; 5 ml. of isotonic sodium chloride solution was added to a 5-mg. bottle of triethylene melamine, which had been kept refrigerated. The solution was mixed immediately before administration. The exact amount was withdrawn (equivalent in milliliter to milligram of drug) and injected promptly intramuscularly. Temperatures were recorded every two hours. After treatment the child received nothing orally for four hours, then water or ginger ale for the next four hours, and then other clear fluids for the third four-hour period. If these were well tolerated, a full fluid diet was allowed and then a light diet, as tolerated, after an additional four hours. The patient was usually discharged about 24 to 36 hours after treatment if afebrile and not vomiting.

Results

A summary of the experience with combination therapy with use of orally given triethylene melamine and radiotherapy is presented in table 1 for the first 33 children treated. The tumor was arrested and useful vision preserved in 12, or 36%. All patients were treated, no matter how large the lesion, if it was felt that some vision could be preserved. However, it is apparent from table 1 that the best results were obtained in the group in whom medium or small-sized tumors were present. Nine of the 11 patients in this group showed favorable response, whereas only 2 of a group of 10 children with large tumors (none of whom would have been treated with x-rays prior to 1953) showed favorable responses to combination therapy.

These findings may be compared with those that have been previously reported by us with others,[6] in which 23% of 122 children treated with radiotherapy alone had the tumor arrested and useful vision preserved. Prior to 1953 the children receiving radiotherapy alone were generally given 5,600 to 8,000 r in air through each of two portals to the tumor (table 2), whereas the patients undergoing combined therapy at present usually receive only 2,400 r in air through each of two portals. In the earlier treatment group, the difference between failure and success was unrelated to the amount of radiation received. Whereas 18% of

the children had died in the original combined treatment group in 40 months, as first reported by us with others,[6b] about 35% had died in the group treated with radiotherapy alone in 10 years. Figures 1 and 2 are reproductions of an artist's sketches of findings in the pretreatment and post-treatment phase of two successful cases of combined therapy (see legends).

Eight patients have been treated with triethylene melamine given intramuscularly. At present seven have tumor arrest with retention of useful vision and one is alive with tumor arrest but no vision. A moderate leukopenic and/or thrombopenic effect was obtained in almost all patients treated intramuscularly, whereas there were many instances in which mild or no marrow depression was observed after oral administration of triethylene melamine. The possibility that larger doses were responsible for better results in the intramuscularly treated group is under study.

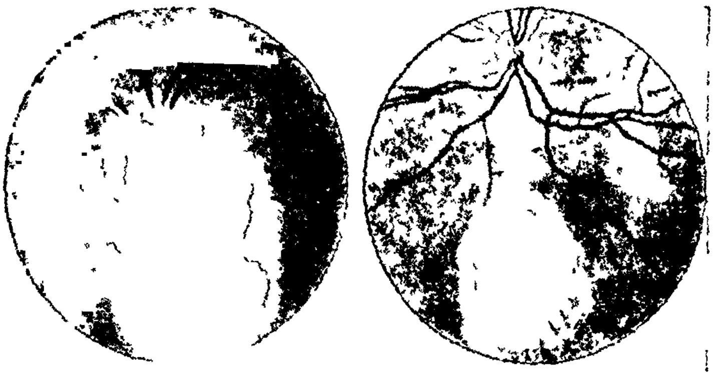

Fig. 1. (table 3, case 4).—*Left*, lesion in left eye before treatment; *right*, lesion in left eye 21 months after treatment

In an attempt to increase manyfold the amount of drug reaching the tumor, in nine instances, as mentioned above, triethylene melamine was instilled under direct operative vision into the internal carotid artery of the side corresponding to the eye to be treated. Patients were selected for this type of instillation of triethylene melamine (1) when the tumor was found to be very large but enucleation was refused by the parents, (2) when tumor cells were seen histologically at the cut end of the optic nerve at the time of enucleation (formerly an invariably fatal situation), or (3) when an orbital regrowth of tumor was present after an earlier enucleation. In addition to triethylene melamine therapy, radiotherapy was given to the eye or orbit, and if necessary orbital exenteration was performed. Table 2 summarizes the results of treatment of these "almost hopeless" cases. In this group two have had the tumor arrested and vision preserved, three have died, and an additional four apparently have active disease. Prior to 1953 these children would have been considered hopeless and would not have been treated.

The heightened local effect of the intra-arterial instillation of triethylene melamine is demonstrated by the findings in the case of a patient in whom enucleation of the right eye had revealed extensive invasion of tumor into the optic nerve. The lesion in the left eye appeared more favorable, and treatment was started with orally given triethylene melamine and radiotherapy. Soon thereafter a mass appeared in the right orbit, followed by intracranial extension. The patient had triethylene melamine instilled into the right carotid artery, and within three weeks a huge orbital mass on the injected side had almost vanished. At autopsy shortly thereafter only a hemorrhagic necrotic residue containing a small number of cells with deep staining nuclei and scanty cytoplasm remained on the right. This was in contrast to findings in the left eye, treated earlier with orally given triethylene melamine and radiotherapy, which showed viable tumor. The intra-arterial method of treatment is under further study.

Toxicity

One child in the series of 50 patients, many of whom had received four to six treatments with triethylene melamine, died of effects directly related to marrow depression (case 19, table 3). This child suffered a head injury while thrombopenia was present and subsequently died at another hospital of a subdural hematoma. In this patient leukopenia had appeared after only two days, a serious prognostic sign in our experience. When leukopenia did not occur before the fifth day, marked depression was rarely seen. Since this episode early in the study, children have received prednisone (Meticorten) and a broad-spectrum antibiotic in an empirical attempt to prevent bleeding manifestations and infection, respectively, if the platelet count fell below 50,000 per cubic millimeter and/or the white blood cell count fell below 2,000 per cubic millimeter. Prednisone was given orally in a dose of 2.5 mg. four times daily until the platelet count returned to 100,000, and the antibiotic was given until the leukocyte count returned to 3,000. Prednisone therapy was then gradually discontinued by reducing the dose in 2.5-mg. steps over a three-week period. In only one instance in the entire series was a transfusion required (case 24, table 3).

The marrow depression that may occur after triethylene melamine therapy is often a useful indicator of adequate dosage. Complete blood cell counts with platelet counts were performed two to three times weekly after treatment. In general, a moderate leukopenia of about 3,000 per cubic millimeter appeared on the fifth day after the intramuscular injection and on the fourth day after the intra-arterial instillation, indicating no significant difference between these two routes of administration. Oral therapy rarely depressed the leukocyte count to the level of 3,000 per cubic millimeter, with the low point reached generally on the ninth day, about double the time interval after parenteral administration. The platelet depression (to 100,000 or below) usually occurred later than the

§ Invasion of distal portion of optic nerve.

‖ Exenteration

¶ Death from subdural hemorrhage after injury maximal leukopenia response, with the low point being reached after intramuscular injection on the 24th day and after intracarotid instillation on the 25th day. The additional safety factor of performing platelet counts is emphasized by the fact that the return of the platelet count to normal occurred later than with the leukocytes. Consequently additional treatment was withheld until the platelets rose above 200,000 per cubic millimeter and the leukocytes above 6,000. Nausea and vomiting occurred in about one-half of the children treated, but was either mild or easily controlled by administration of chlorpromazine. Temperature as high as 101 F (38.3 C) was noted in a few of the smaller children during the first 24 hours.

Comment

The combination of radiotherapy and triethylene melamine therapy has resulted in the apparent arrest of retinoblastoma and the retention of useful vision in 21, or 42%, of 50 children so treated. If the nine patients who received intra-arterial chemotherapy in an attempt to control an otherwise "hopeless" situation are excluded, then 19, or 46%, of 41 patients have exhibited apparent arrest of the tumor. This result has shown combination therapy to be significantly better than the method used in an earlier series [6b] in which radiotherapy alone resulted in the apparent arrest of retinoblastoma, with retention of useful vision, in 28 patients, or 23%, of 122 treated. (An additional study is now in progress in which alternate selection of patients receiving either combined therapy or radiotherapy alone is being used in order to obtain statistical information that may confirm the presumption that combination therapy seems more effective in selected cases than radiotherapy alone.)

Table 4.—*Combination Therapy of Retinoblastoma with Use of Radiotherapy and Triethylene Melamine Given by Oral and Intramuscular Route*

Size of Tumor	No.	Tumor Arrested: Vision	Tumor Arrested: No Vision	Tumor Not Controlled: Alive (Enucleation)	Tumor Not Controlled: Died
Large	15	6	2	6	1
Medium	6	5	1		
Small	8	7			1
Total	29	18(62%)	3(10%)	6(21%)	2(7%)

The group treated with radiotherapy alone received 5,600 to 8,000 r in air to the tumor, whereas the present group generally received only 2,400 r in air to the tumor in combination with triethylene melamine. Thus the hazard of a late hemorrhagic retinitis resulting in blindness was almost entirely avoided in the combined treatment group, while the results of therapy were as good or better. Furthermore, the patients in the earlier series, treated prior to 1953, generally had either small or medium-sized tumors. Since the advent of combined therapy, all patients in whom any useful vision was present have been treated, including 15 with large tumors.

The results achieved with combination therapy of patients with either small or medium-sized lesions indicate that the tumors in 12 of 14 patients, or 85%, apparently have been arrested, with retention of useful vision. Extension of the group to include all but the "almost hopeless" shows that the tumors in 18 of 29 patients, or 62%, apparently have been arrested, with retention of useful vision (table 4). Future results may prove to be better with the children receiving triethylene melamine intramuscularly, since the small group of patients treated intramuscularly to date has the highest percentage of arrested tumors (tables 1 and 3).

The intramuscular dose that we have selected as optimal is approximately 0.1 mg. per kilogram. Because of the variation in individual sensitivity, subsequent therapy in each patient is based on the initial hematological response. The effective intramuscular dose was approximately one-third to one-half the oral dose, as has been previously reported by Karnofsky.[7]

The total dose employed has been empirical, with an average course of 15 mg. orally or 6 to 10 mg. intramuscularly extended over a 6-to-12-month period. These young children apparently tolerate much larger doses than adults, since the recommended parenteral dose of triethylene melamine in adults is only 6 to 12 mg.

Of interest is the finding that additional chemotherapy in these children with normal bone marrow may have a lessened effect on marrow activity as treatment continues, possibly indicating the presence of an adaptive mechanism in normal marrow. This situation differs sharply from that seen in patients with Hodgkin's disease or other lymphomas, since in these patients the marrow seems less able to cope with additional courses of mustard-like agents as the disease progresses.

The combination of radiotherapy and chemotherapy in treatment of tumors has many theoretical bases. Research by Goldberg and Schoenbach,[8] and by Timmes, Haddow, and others of their group[9] have indicated that the effect of these agents is apparently at different points on the chromosome of the dividing nucleus. If such is the case, then a synergistic action is a possibility.

A concentration of these children with a rare tumor at one medical center provides the chemotherapist with a unique situation. In addition one is dealing with an easily visible, local, and circumscribed tumor, magnified 16 times by the ophthalmoscope, so that combination therapy can be better evaluated than is generally possible in Hodgkin's disease, lymphosarcoma, or other epithelial tumors. Since retinoblastoma is an unusual cancer with a strong clinical resemblance to the lymphomas in its response to radiotherapy and the alkylating agents, one may have here a pilot-type study in which to observe the effects of combined therapy.

Summary

Because of the possibility of synergism between radiotherapy and triethylene melamine therapy, a study was commenced in January, 1953, at the Institute of Ophthalmology and the Columbia-Presbyterian Medical Center in which 50 children with retinoblastoma received combined therapy. This combination appeared to be both feasible and apparently successful in arresting retinoblastoma in a significant proportion of children with early disease. It was found that triethylene melamine could be safely administered to children in doses proportionately larger than those given to adults and that the route of choice was intramuscular.

DUCK-EMBRYO RABIES VACCINE

STUDY OF FIXED VIRUS VACCINE GROWN IN EMBRYONATED DUCK EGGS AND KILLED WITH BETA-PROPIOLACTONE (BPL)

Franklin B. Peck Jr., M.D., Horace M. Powell, Sc.D.
and
Clyde G. Culbertson, M.D., Indianapolis

• *Improvements in the methods of immunizing against rabies are needed because neuroparalytic accidents are known to have occurred following the use of present methods. The use of embryonated duck eggs in place of rabbit brain for propagating the virus eliminates the myelin, which has been suspected of contributing to the nervous complications. The animal experiments here described showed that duck-embryo rabies vaccine could be killed by dilutions of beta-propiolactone not exceeding 1:4,000. Killed under these conditions, the virus was shown to be antigenic in mice. Detectable antibody appeared between 7 and 10 days after the first inoculation and continued to be present on the 15th and 30th days In treating bites of rabid animals, antibody must be made to appear as early as possible. The absence of brain tissue in this preparation has distinct advantages*

The occurrence of neuroparalytic accidents during rabies prophylaxis has been an ever-present hazard to successful treatment. Recent figures indicate that these accidents occur approximately once in 500 to 600 treatments.[1] Conventional antirabies vaccine propagated in rabbit brain contains myelin, which has been implicated as the factor causing central-nervous-system complications.[2] Alternative methods of vaccine preparation include (*a*) purification of brain vaccine or (*b*) growth of the virus on non-nervous tissue. We have found, in following the latter direction, that embryonated duck eggs suffice for growing fixed rabies virus.[3] Furthermore, the vaccine produced by this method is free of neuroparalytic factors, as determined by adjuvant tests in guinea pigs.[4]

We have recently described the use of embryonated duck-egg antirabies vaccine in humans.[5] One-year-old freeze-dried attenuated virus vaccine was used. The antibody response in this study was quite satisfactory, being both early in appearance and present in a great proportion of patients studied. However, it appeared prudent to kill the virus used in this vaccine providing it would maintain adequate antigenicity. This was accomplished by the use of beta-propiolactone (BPL). This report concerns laboratory and clinical aspects of beta-propiolactone–killed rabies vaccine.

Laboratory Studies

Virucidal Action of Beta-Propiolactone.—Doubled dilutions of beta-propiolactone were added to a series of six 100-ml. amounts of virus suspension. Final concentrations of beta-propiolactone in the virus suspension were from 1:1,000 to 1:32,000. After refrigeration of the suspension at 4 C for 24 hours, acidification brought about by breakdown of beta-propiolactone was corrected. Decimal dilutions of each virus suspension were injected intracerebrally into groups of five mice to determine the titer, if any, of live virus in each preparation. Untreated virus was also employed as a control. All virucidal tests were conducted under refrigeration, due to the lability of the virus at incubator temperature.

It is evident (table 1) that concentrations of beta-propiolactone of 1:1,000, 1:2,000, and 1:4,000 killed embryonated duck-egg fixed virus. The 1:8,000 to 1:32,000 concentrations of beta-propiolactone failed to do so. In a separate study (not shown) it was found that a 1:6,000 concentration of beta-propiolactone also was effective in killing the virus. Thus it was demonstrated that preparation of killed antirabies vaccine could be attempted with concentrations of beta-propiolactone up to 1:4,000 but not with concentrations of 1:8,000 or weaker.

From the Lilly Laboratory for Clinical Research, Indianapolis General Hospital, and the Lilly Research Laboratories

Immunizing Potency.—Four of the suspensions described above were next tested as antirabies vaccines in official tests of the National Institutes of Health[6] in white mice. The NIH standard vaccine was used as a control. It was observed (table 2) that the three strongest concentrations of beta-propiolactone studied were virucidal and immunized mice; however, the best immunizing action was secured with the weakest virucidal concentration of beta-propiolactone (1:4,000). The stronger concentrations were less antigenic.

TABLE 1.—*Virucidal Action of Beta-Propiolactone in Duck-Embryo Suspensions**

Virus Dilutions	Dilutions of Beta-Propiolactone						
	1:1,000	1:2,000	1:4,000	1:8,000	1:16,000	1:32,000	Control
10^{-1}	4/4	5/5	5/5	2/5	0/5	0/5	0/5
10^{-2}	5/5	5/5	5/5	5/5	3/5	0/5	0/5
10^{-3}	5/5						0/5
10^{-4}	5/5						0/5
10^{-5}							0/5
10^{-6}							2/5
							4/5

* Results given as ratio of mice surviving to mice injected. Mice were inoculated intracerebrally with suspension of virus and beta-propiolactone. Concentrations of beta-propiolactone up to 1:4,000 successfully inactivated strongest dilution of rabies virus suspension.

Consistency of Potency.—A series of batches of killed vaccine was then prepared with beta-propiolactone. None contained live virus, as evidenced by intracerebral injection of the vaccines into white mice. All batches, or lots, passed the NIH safety tests,[6] which included single subcutaneous injections of 0.25 ml. into white mice and single subcutaneous injections of 2.5 ml. into guinea pigs. The potency of these vaccines, when tested according to official NIH methods,[6] is indicated in table 3. All lots of this vaccine were much better than the standard control vaccine. Lot 698C was made with 1:2,000 concentrations of beta-propiolactone and the rest with 1:4,000 concentrations. The latter concentration was made routine on all succeeding batches.

Heat Stability.—Several lots of the beta-propiolactone-killed vaccine were subjected to heating at 37 C for periods of two or four weeks. Table 4 shows potency determinations of these various lots both before and after the periods of heating. It is observed that all of the vaccines are considerably better than the control vaccine even after four weeks of heating.

Antibody Response in Monkeys.—Fourteen daily doses of vaccine were given to each of four cynomolgus monkeys. Vaccine from lots 696 and 703 was used (tables 3 and 4). Standard serum-virus neutralization tests[7] were conducted in mice with use of 0, 15, 30, and 60 day serum specimens drawn from the monkeys. Antibody titers were computed by the method of Reed and Muench.[8] The series of injections was uneventful, and antibody response was good (table 5).

TABLE 2.—*Effect of Beta-Propiolactone on Antigenic Potency of Duck-Embryo Rabies Vaccine*

Concentration of Beta-Propiolactone*	Virus Viability	Potency† of Vaccine
1:1,000	Killed	0.55
1:2,000	Killed	1.25
1:4,000	Killed	3.28
1:8,000	Living	5.79

* Beta-propiolactone in concentrations of 1:4,000 produced the most immunizing potency with the least amount of damage to the killed virus vaccine.

† Times better than standard vaccine of National Institutes of Health.

Observations.—It is apparent that the use of beta-propiolactone in 1:4,000 concentrations is regularly successful in killing duck-embryo fixed rabies virus. The killed-virus vaccine made in this manner also acted as an effective antirabies vaccine, as judged by NIH mouse-immunization tests. It also appeared that the vaccine could withstand at least a moderate amount of poor storage conditions such as might be encountered in clinical use. Cynomolgus monkeys were effectively immunized by 14 daily injections without untoward after-effects, indicating possible clinical adaptability of the vaccine.

Clinical Studies

Clinical response to the vaccine was studied in 32 male volunteers. None had a history of allergies or prior antirabies-vaccine therapy. Twenty-one complete courses of 14 injections of vaccine were given. Also, 7 daily inoculations were given to six subjects, two of whom were originally scheduled to receive 14 injections. One person received six of seven inoculations, the seventh being omitted due to reaction. Four individuals were dropped from the study at its onset, three at their own request and one due to acute intercurrent illness. Blood specimens were obtained from all subjects prior to the first vaccination and again on the 10th, 15th, and 30th day after the first inoculation. In addition, the five individuals receiving a total of seven inoculations had a seventh-day bleeding. The entire group was divided into three subgroups, each of which received a different batch of vaccine (group A received lot 703; group B, lot 710; and group C, lot 712). Injections were made subcutaneously on the abdomen at a different site each day. The patients were checked daily for local or systemic reactions.

TABLE 3.—*Consistency of Potency of Beta-Propiolactone-Killed Duck-Embryo Rabies Vaccine*

Lot	Potency*	Lot	Potency	Lot	Potency
689-C	1.2	698-B	2.6	710	3.5
689-D	3.2	703	3.0	712	2.4
696	3.3	706	4.7	714	2.4

* Times better than standard vaccine of National Institutes of Health

Reactions to Treatment.—Two individuals were not given the entire series of 14 injections due to the occurrence of local induration severe enough to warrant discontinuation of an elective procedure. One other subject who was originally scheduled for seven injections developed chills, fever, and malaise after injection number six, and use of the vaccine was discontinued. A transitory stinging sensation, usually lasting no longer than a minute or two, was noted by all subjects at the time of injection. Tenderness at the injection site developed in a majority of patients, lasting from 24 to 72 hours. This tenderness was not incapacitating and was not considered to be a major problem.

Erythema was observed in about one-half of the individuals, the great majority of instances being sporadic in onset. Four subjects exhibited consistent erythema with each injection, the erythema being more severe as the sixth and seventh injections were given. Induration of varying degrees was noted in several subjects. Again, it was sporadic in onset but tended to be more common during the middle third of the treatment. Three individuals, all of whom had induration, also exhibited transitory regional lymphadenopathy. The local reactions to the vaccine did not appear to be as frequent as those seen when phenolized vaccine of brain origin is administered.

TABLE 4.—*Heat Stability of Duck-Embryo Rabies Vaccine Killed with Beta-Propiolactone*

Lot	Potency* Before Heating	2 Wk. at 37 C	4 Wk. at 37 C
689 D	3.28	3.96	1.87
696	3.34	1.75	3.02
703	3.08	5.06	10.00
710	3.5	2.56	3.61
712	2.44	2.43	2.26
714	2.41	4.49	1.76
722	2.24	6.89	5.96

* Times better than standard vaccine of National Institutes of Health.

Systemic Reactions.—One subject in this series developed fever, chills, anorexia, and malaise 14 hours after receiving the sixth of seven injections. It was thought that the illness represented a reaction to a foreign protein, and administration of the vaccine was discontinued. Recovery was uneventful. The patient recalled that he had had the same type of reaction to influenza vaccine 11 years previously.

Development of Virus-Neutralizing Antibodies.—All serums were studied for antibody to rabies. Titers of antibody concentration were based on standard bioassay procedures in which 100 L.D.$_{50}$ of challenge virus and 0.03 ml. of serum in varying dilutions were inoculated intracerebrally into six mice per each serum dilution.[7] The titers (table 6) were expressed as the reciprocal of the serum dilution needed to protect half the mice. In the group receiving 14 injections, all had developed antibody by the 10th day after the first injection. Antibody continued to be present on the 15th and 30th days. Only one of the group receiving seven inoculations had demonstrable antibody on the 7th day, although five of six had antibody on the 10th day. *It is interesting to note that the individual having the systemic reaction after the sixth injection had a good antibody response on the seventh day.* No differences were seen between the lots of vaccine used, either in the time of onset of antibody response or in the height of the titers. It is apparent that detectable antibody appears between 7 and 10 days after the first inoculation. No correlation could be established between the degree of local reaction and the height of antibody response in this study.

TABLE 5.—*Antibody Response in Cynomolgus Monkeys Receiving Duck-Embryo Rabies Vaccine**

Monkey	Lot	Day No. 1	15	30	60
434	696	0	12	85	25
415	696	0	64	57	23
416	703	0	83	74	12
417	703	0	12	10	10

* Antibody titers expressed as reciprocal of serum dilution saving half the mice as determined by the method of Reed and Muench.[8]

Comment

It is obvious that a prime necessity in treating bites of rabid animals is the early appearance of antibody. This is especially true if the bites are on the face and neck or if there has been massive inoculation of street virus into the wound. The use of hyperimmune serum will no doubt add to the effectiveness of treatment of these bites. It still remains, however, that early formation of active antibodies plays a very important part in prevention of rabies in humans. Rabies vaccine of duck-embryo origin produced antibodies in all subjects within 10 days. There did not appear to be a variation in antigenicity between the lots tested clinically, and the results correlate closely with those observed in tests on animals. From this it would appear that tests on animals are sufficient to establish the antigenic potency of the vaccine. The absence of brain tissue in this preparation has distinct advantages. Neuroparalytic accidents should be materially reduced in frequency if not completely eliminated. This may help the physician in solving the distressing problem of whether to give a course of vaccine to questionably exposed patients.

TABLE 6.—*Serum-Virus Neutralizing Titers in Human Subjects Injected with Beta-Propiolactone–Killed Duck-Embryo Rabies Vaccine*

Vaccine Lot	Doses, No.	Subject	Antibody Titer* on Indicated Day† After First Inoculation 7	10	15	30
703	14	A-1		16.0	22	32

722	7	C-5	ND	9	10.9	45.4
712	6	C-8	7.1	43.4	140	52

* Antibody titer expressed as reciprocal of serum dilution protecting half the mice, as calculated by method of Reed and Muench.[8] Titers of <4 indicate immunologic response in which some mice lived in test, but too few to give 1:4 titer.

† Zero day titers 0 in all cases.

‡ ND = not done.

As this vaccine contains foreign protein, one must expect to see the development of local sensitivity in some individuals, even though embryonic tissue is poorly antigenic. The fact that 14 injections are given increases the chance of sensitivity occurring. That it has not occurred in a greater number of subjects has been gratifying. Systemic reactions to foreign protein also must be anticipated in a small percentage of individuals. Since there is a greater incidence of allergic reactions in subjects with allergic histories, one should be cautious in the use of this vaccine in these individuals. This is especially true if the allergy is to chicken-egg albumin.

THE ENIGMA OF CAUSE OF DEATH

Alan E. Treloar, Ph.D., Minneapolis

• *The causation of a given death is always multiple, so that the necessity of selecting a single cause for purposes of tabulation has become a distressing problem. The solution depends on the purpose for which the information is to be used. For the purposes of preventive medicine the single cause of death hitherto given has been very useful, but it would be even more valuable to indicate all those terminal morbidity conditions that meet desirable standards in defining important diseases. This would also relieve the physician of the unwelcome task of designating the dominant cause unless he wishes to do so by underscoring one.*

However strong may be our defenses against becoming victims of the dramatic statement, whether by propagandist, preacher, or politician, we are nevertheless enticed by its stirring of emotion and may use it on occasion to achieve a purpose when reason alone seems insufficient. The inadequacy of man's reason to cope fully with the problems of intimate death is a matter of common observation, and the power of emotion to bridge those voids is traditionally exploited through dramatic expression.

There seems to be a substantial carry-over from this emotional reaction to death as a personal experience to the more objective contemplation of death in general. Assertions that selected diseases are the "great killers of mankind" are common in high places. National societies promoting campaigns for funds to study those diseases contend for each death to be assigned to the disease of their special interest; thus will their claims for priority in charitable donation gain the desired weight provided by statistical evidence. Vital statisticians routinely respond in such ways as fall within their province to "fix the blame" or, in more formal language, to secure with scientific accuracy, from the medical profession, coroners, or others, a specification of the "cause" of each death. Pursuit of this objective is certainly laudable from all conventional viewpoints, but in so conforming one may become a victim of habit rather than an alert pursuer of well-reasoned objectives.

Public health workers are marshalled as forces for the preservation of good health in their respective communities through community action. Maintaining health calls for quick remedial action with respect to any defection, and most certainly before death forecloses all possibility of change. Morbidity is the prime interest, the challenge to action; mortality is merely a measure of defeat. We may appropriately mourn the dead, but let it be only in search of better means to protect the living.

In most instances, medical certification of cause of death has been vigorously sought because of conviction that the death certificate should help to define the morbidity problem. Good morbidity data of complete community coverage have not been available from other sources. If such data were readily available, our interest in cause-of-death certifications would surely vanish. But certainly no statistician worthy of his salt is going to accept even the best mortality records as other than a grossly biased sample of morbidity conditions in a total community.

Concepts of Cause of Death

It is a false proposition that each death is a response to a single cause. Of this we are well aware. Admission of multiple causation for each death is tacit in the certificate itself. We have long striven for entry of a sequence of causes rather than a single cause. As a result of this, the selection of one cause for tabulation purposes has itself become a major problem for us, leading to much juggling of terms, rules, and instructions, to the distress of the medical profession as well as the statisticians. Efforts in recent years to solve the problems of tabulation and interpretation of assignment of multiple causes represent an attack on a basic problem and clearly indicate that causation of death is not considered singular.

Cause is defined by common understanding as "that which produces an effect"; or, more cautiously, as "the group of circumstances that must precede and that invariably result in an effect." These are common dictionary forms of definition. There is ample testimony in the writings of philosophers and scientists alike, from at least the time of Aristotle onward, that assignment of cause is a metaphysical indulgence and beyond the scope of scientific undertaking. This problem has had some of its best emphasis in the work of biometricians. Two founders of the biometric school have contributed notably to clarification of the causa-

---

Professor of Biostatistics, School of Public Health, University of Minnesota. Dr. Treloar is now Director of Research, American Hospital Association, Chicago.

Read before a joint session of the American Association of Registration Executives and the Statistics Section of thte American Public Health Association at the 83rd Annual Meeting of the American Public Health Association, Kansas City, Mo., Nov. 17, 1955.

tion issue. Francis Galton's accomplishment in providing a measure of incomplete association is well known. Too often, in disputation of the merit of his technique, we lose sight of the broader concepts his work opened to our view. His book "Natural Inheritance"[1] tremendously impressed a much younger scholar of high attainment in law, mathematics, and the sciences, Karl Pearson. Analysis of the foundations of scientific reasoning had been absorbing much of the young man's attention and led to another notable book, "The Grammar of Science," which gave considerable attention to the subject of causation.[2] Close companionship of these two men in the following years, with considerable fusion of their ideas a natural product of the meeting of their minds in repeated discussion, led to a synthesis of their thinking on the subjects of correlation and causation, to which each had contributed so much independently.

Pearson's biography[3] of his close friend gives clear definition of their viewpoint in a familiar statistical form worthy of rather full quotation here:

> . . . correlation . . . was to replace not only in the minds of many of us the old category of causation, but deeply to influence our outlook on the universe. The concept of causation—unlimitedly profitable to the physicist—began to crumble to pieces. In no case was B simply and wholly caused by A, nor indeed by C, D, E and F as well! It was really possible to go on increasing the number of contributory causes, until they might involve all the factors of the universe. . . . Henceforward the philosophical view of the universe was to be that of a correlated system of variates, approaching but by no means reaching perfect correlation, i. e. absolute causality, even in the group of phenomena termed physical.

Lest there be any tendency to regard this sort of thinking as outmoded, may I quote from a recent work of J. Robert Oppenheimer.[4] He writes thus of the new physics: "This is a very different view of reality from Newton's giant machine. It is not causal; there is no complete causal determination of the future on the basis of available knowledge of the present . . . every observation on a system reveals some new knowledge as to what its state is that did not exist before, and could not by analysis and mathematical computation have been obtained."

Complexity of Cause

What is the implication of all this for our problem of cause of death? By way of introduction to this, I would ask indulgence in considering first a simple illustration not involving health. Boys are at play in an open lot beside a house, active in a game simulating baseball. A powerful swing of the bat fails to make contact with the ball in the proper manner, and the ball spins wide of the intended course to come to rest within one of the rooms of the house, leaving a shattered pane of glass as vignette to its flight. The owner of the house, irate if not irrational in his questioning, demands to know who broke the glass, so that responsibility for its replacement may be clearly attached. To him the 'cause" of the broken pane is to be determined with one objective in view—satisfaction of his just claim for damages through assignment of responsibility to a source from which payment may be expected. But did the boy at bat break the pane of glass, as many would chorus in support of an obvious argument? The ball? Did not the pitcher play a part? And also the circumstances that led to selection of that place to play in, and the countless number of antecedents throughout past time (including all ancestors) that led to those circumstances? An articulate ball in turn could well protest that it alone did not break the glass—just as my child comments on milk flooding outward on the tablecloth from her overturned glass, "It spilled!"

It is clear that we can wrangle indefinitely about this matter of causation in specific illustrations. But is it not also clear that all observations are elements in sequences of events from deep in the past into an indeterminate future? Of the facts of broken glass or spilled milk there is no doubt. And that each was the inevitable outcome of the long line of antecedents that preceded it, constituting the causal system, we feel confident there is also no doubt. Are not causes just the members, infinite in number, of causal systems that in their totality are beyond our comprehension? We may select from such a system an individual factor and, in assigning to it an importance that is suitable to our reasoning of the moment, claim it to be the cause of the result. This is clearly arbitrary selection. We habitually prescribe that all else outside those members of the system that we choose to consider shall be deemed extraneous for purposes of discussion. In this sense a weight added to one side of a balance may be considered the sole cause of a subsequent movement in the balance. This is causation in the Newtonian sense. Its justification is implicit in the simplicity of the situation studied.

A question of major concern to us just now is whether we can establish sufficient analogy between such simple situations and the very complex one of establishing cause of death. It may help us here to consider life as like a functioning motor, self-regulating and capable of many internal compensations, vulnerable to external attack and internal decay. Actuarial tables define its expected duration under the hazards characteristics of specific time periods. Any predominant factor or incident of outstanding importance leading to unexpectedly early breakdown of this machine may be accepted by us all, without conflict of opinion, as an appropriate cause to which the death (complete and irrevocable stillness in the motor) should be assigned. Accidents and acute communicable diseases come quickly to mind as illustrations of such factors. Other elements playing their normal roles in the complete causal system are readily accepted as being relatively unimportant and are dismissed from consideration. The arbitrary designation of one cause is nevertheless an overriding simplification. Its acceptance is made possible through unanimous agreement that it serves the purpose for which knowledge of cause is required, all other causal factors are in this light trivial.

Shift the disease from acute to chronic or the accident to suicide, for instance, and it may become extremely difficult any longer to get anything approaching unanimity of agreement as to what is now to be accepted as the responsible cause. Those advanced in years are not infrequently known to be host to more than one disease condition, each of which in some degree impairs ability to function. Death finally comes, as it must to all, and the necessity of specifying a cause on the death certificate initiates somewhat of a scramble. Not infrequently what appeared to be a rather clear-cut syndrome of clinical symptoms, giving the internist complete confidence in what he would assign as the cause of death, fails to jibe with findings at autopsy. How often it is true that the pathologist would insist on some other entry in the medical certification of cause of death, if that document were not already completed and filed out of his reach.

Let us consider for a moment a specific case. A person is bothered in childhood by undiagnosed rheumatic fever, but he recovers and goes on into adult life with a resultant heart defect. The latter is not serious enough to come to medical attention until hospitalization for tuberculosis leads to its discovery. In the course of time his tuberculosis is brought under control, and he is released to a new pattern of "normal activity." Some years later he is one of the victims in an automobile accident in which he suffers trauma, considerable laceration, and seemingly serious loss of blood. Death shortly after arriving at the hospital results in certification of accidental death. But autopsy leads to a pathologist's verdict that the diseased condition of the heart was the primary culprit in this death. The pathologist also discovers cancer of the bladder that, in a relatively short period of time, would undoubtedly have led to death if not caught and successfully treated. The tuberculosis does not seem to play a role in the death and is disregarded.

We may all agree that the outstanding incident among the antecedents to death in this particular case was the automobile accident and that the death should be assigned to the appropriate subclassification on the list of accidental deaths, the strain on the heart being considered as a by-product of the accident. Undoubtedly many interests will feel well satisfied by this procedure. From the point of view of health interests, however, the accident is no more than an incident; it belongs in the category of a "last straw that breaks the camel's back." Any fight among various societies for this death as belonging to their propaganda campaigns is justifiable; the record belongs in a very real sense to every one of them. The body is certainly part of the wreckage of an accident; it is also mute testimony to the wastage of rheumatic fever and heart disease, tuberculosis, and cancer. Important information on health is lost by not assigning the case to each disease category to which it properly belongs, not as a death but as an impoverished body recently alive.

The difference between this sort of situation and that of the acute communicable diseases is not fundamentally that deaths are separable into two categories with respect to causation—the simple and the complex; it is fundamentally a contrast in the relative ease with which we can secure unanimity of agreement in selecting one item out of a causal system as being the important one for the purpose in view. Let us emphasize those last words: for the purpose in view.

Effective Use of Knowledge

What is the purpose behind selection of cause of death? The appropriate answer to this question must inevitably be colored by the viewpoint of the respondent. A lawyer will think of legal reasons; an insurance company executive would consider first the obligations that the company has undertaken and possible exceptions that must be considered. Members of the health professions will have in mind the picture of morbidity in the population that they are attempting to serve. One thing will be common to all efforts to answer the question: an attempt to select the most important causal factor from the point of view of the respondent.

Our responsibilities in public health necessitate our knowing as much as possible of the total morbidity picture in each community that we serve. The medical certification of cause of death contributes to that knowledge. Effective use of that information is surely the primary justification for securing it. When study of the prevalence of disease is the task to which we claim dedication, it is most certainly wasteful of opportunity to allow ourselves to become involved in misleading argument about single cause-of-death selections. The prevalence of disease in a community will not be measured by selecting one only from these attendants at the end of life's run. We would like to have the complete morbidity picture for the whole of each life story as it unfolds, but means are not available to us for getting that. We accept the death story as an available fragment for what it may be worth with respect to those who remain.

Passing of the era of acute communicable diseases as major killers in the United States has already had a very substantial impact upon our programs in public health. We have instituted many changes of activity in an effort to meet an altered balance of needs. Some of these changes may prove to have been impulsive and taken too early. But certainly we must turn attention to deeper study of the endemiology of chronic disease. And in that connection especially, I am sure we should benefit from thought concerning the fundamental nature of causation in relation to death, and our basic reasons for seeking causes in this connection.

A Postlude

In closing this discussion I would like to anticipate a very few of the questions that must follow as a natural sequel:

1. Tabulations of deaths by specific causes have been very useful in the past. Are they to be abandoned now? Answer: Not at all. Indeed the tabulations should be extended to cover all entries on the medical certification of cause of death that meet desirable standards in defining important diseases. But certainly the term "specific causes of death" should be replaced by a more realistic term such as "terminal morbidity conditions." Perhaps a new term like "conterminous morbidity" might arise.

2. Should use of death rates specifying a cause be continued in the present form? Answer: Preferably not, even though the sophisticated may not abuse the misleading title. But for all, including this elite group, we should have a new class of rates defining proportionate morbidity at time of death. Under this title would be defined the relative frequency with which diagnosed heart disease, cancer, tuberculosis, cerebral accident, and each other causal entity of sufficient importance to receive attention appeared among those

deceased. These rates would be highly informative, covering prevalence of disease prior to decease far better than death rates specifying a cause can possibly do. It would be most important to have such rates specific for homogeneous population groups, especially by age.

3. What changes would seem desirable within the medical certification portion of the death certificate? Answer: A careful revision of wording to win better cooperation from the medical profession. The physician should be encouraged to report disease, in the detection and treatment of which his competence is acknowledged and his aid has been sought. His assistance would be given accordingly. Noncooperation to the point of antagonism is risked by superimposition on him of the unwelcome role of seer in the metaphysics of causation. We should remove all obligation to indicate a single cause for tabulation purposes. Selection of a dominant cause to which the physician would give emphasis should be voluntary, indicated perhaps by an underscore. Perhaps our vital statisticians may reconsider past decisions on this in a new light. Perhaps also business interests that occasionally pin their operations to single causes of death will reconsider the wisdom of undertakings based on vague definitions that may promote falsity.

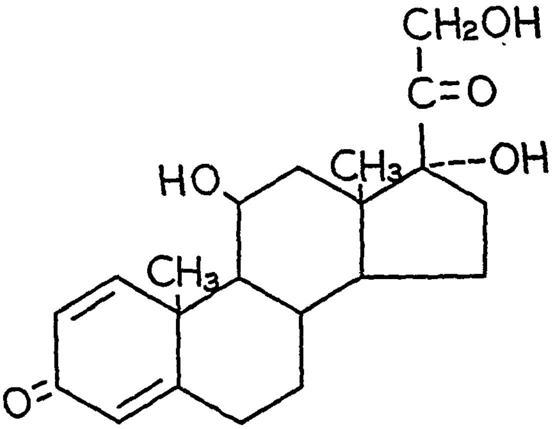
CLINICAL NOTES

THERAPEUTIC ASSAY OF TOPICALLY APPLIED PREDNISOLONE ALCOHOL IN SELECTED DERMATOSES

Erwin H. Zimmerman, M.D., Huntington, N. Y.

Prednisolone alcohol (Meticortelone) is a synthetic crystalline steroid with the following structural formula:



Its structure differs from that of hydrocortisone free alcohol by the presence of a double bond between C_1 and C_2. In a recent study of the effects of orally administered prednisolone, Bunim, Pechet, and Bollet[1] reported prednisolone to be approximately two to three times as effective as hydrocortisone as an antiarthritic and anti-inflammatory agent, yet its use was unaccompanied by an increase in the severity of undesirable side-effects. Goldman, Flatt, and Baskett[2] similarly found prednisolone to be more effective than hydrocortisone when administered orally in various dermatoses. Their studies indicated that prednisolone was four to five times as effective, dosage for dosage, as hydrocortisone. Since both hydrocortisone acetate and hydrocortisone free alcohol have been reported to be of value in the topical therapy of various dermatoses and to be of equal therapeutic value in equal concentrations,[3] it was thought worthwhile to compare the clinical effect of topically applied prednisolone alcohol with that of hydrocortisone free alcohol. In this way, it could be determined whether prednisolone was more effective than hydrocortisone as a topically applied medicament.

Preliminary Study

In a preliminary study, 20 patients with various dermatoses were treated by the simultaneous paired comparison method with ointments containing prednisolone alcohol (either 0.25% or 0.5%) in a white petrolatum base applied to one of two symmetrically situated areas and an ointment containing hydrocortisone free alcohol (1%) in a water-washable base applied to the other. In 14 of the 20 cases, the prednisolone alcohol in both the 0.25% and 0.5% concentrations proved to be more effective than, or as effective as, the hydrocortisone free alcohol, with the 0.5% concentration being the more effective of the two. Although this preliminary study indicated that prednisolone was of distinct value when topically applied, the fact that the prednisolone and the hydrocortisone were incorporated in different bases might have accounted for the difference in their therapeutic efficacy. The results, however, were promising enough to warrant further comparative studies, with use of identical vehicles.

Results

The present study is an attempt to compare the effectiveness of prednisolone alcohol and hydrocortisone free alcohol, with the factor of different ointment bases eliminated. It is divided into two parts; in the first part, the clinical effectiveness of a topically applied preparation of prednisolone alcohol (0.5%) (Meti-Derm) in a water-washable base (Procutan) was compared with that of hydrocortisone free alcohol (1%) (Cortifan) in the same base. A total of 137 patients were treated with these two preparations. The 16 dermatoses listed in table 1 were represented in this group of patients.

Whenever possible, the preparations were assayed by the simultaneous paired comparison method, i. e., the simultaneous application of the prednisolone alcohol (0.5%) cream to one of two symmetrically situated areas or lesions and the hydrocortisone free alcohol (1%) cream to the other. Patients were given adequate amounts of each of the preparations, which were clearly labeled as to both the site of the application and the frequency of applications (three to four times daily). Treatment periods varied from four days to eight weeks, the average being two to three weeks. Patients were observed at approximately weekly intervals for evaluation of both subjective and objective improvement.

The results of this portion of the study are given in table 1. It will be noted from this table that it was possible to carry out the simultaneous paired comparison method in 128 of the 137 cases. Treatment with the prednisolone alcohol (0.5%) cream was more effective than, or equally effective as, with the hydrocortisone free alcohol (1%) cream in 99 out of 128 cases. In nine cases it was not feasible to carry out a simultaneous paired comparison because of the body areas involved. These patients were treated with the prednisolone cream only. In eight of these the prednisolone produced a definite marked improvement, and in only one case did it fail to produce any improvement.

In an effort to determine if any of the therapeutic effectiveness of the prednisolone was due to the water-washable base itself, 24 patients were treated by the use of the simultanous paired comparison method, with the prednisolone alcohol (0.5%) cream administered to one area and a placebo water-washable base used on a symmetrically situated area. This formed the second part of the study, and the results are tabulated in table 2.

In both parts of the study a total of five patients complained of irritation and increased pruritus caused by both the prednisolone and hydrocortisone creams, although only three of these showed objective clinical evidence of an allergic eczematous reaction in the areas where the medicaments were applied. These five patients were given patch tests with the water-washable base, with prednisolone alcohol (0.5%) in a petrolatum base, and with hydrocortisone free alcohol (1%) in a petrolatum base, the medicaments having been applied under a standard closed patch and read after 48 hours. The three patients who had an eczematous reaction clinically showed a positive reaction to the water-washable base only. None of the five patients tested showed a positive reaction to either the prednisolone or hydrocortisone in the petrolatum base. In the other two patients, patch tests were negative, and further patch tests to both the prednisolone and hydrocortisone creams were likewise negative. Two other patients complained of slight irritation from the hydrocortisone cream, despite a definite objective improvement of the lesions. Thus, seven patients complained that one or both of the medicaments caused some degree of irritation subjectively. Only three of these proved to have an actual allergic eczematous reaction, and this was to the water-washable base itself. There was no single instance of an allergic sensitization to either the prednisolone alcohol or the hydrocortisone free alcohol.

TABLE 1.—*Comparison of Prednisolone Alcohol (0.5%) Cream with Hydrocortisone Free Alcohol (1%) Cream*

Dermatoses	Total No. of Cases	Prednisolone More Effective	Prednisolone Equally Effective	Prednisolone Equally Ineffective	Prednisolone Less Effective	No Comparison

Total	137	48	51	18	11	9

TABLE 2.—*Comparison of Prednisolone Alcohol (0.5%) Cream with Placebo Water-Washable Base (Procutan)*

Dermatoses	Prednisolone More Effective	Prednisolone Equally Effective	Prednisolone Equally as In-Effective	Prednisolone Less Effective	Total No. of Cases
Allergic contact dermatitis	5	1	0	1	7
Atopic dermatitis	5	0	0	0	5
Seborrheic dermatitis	3	0	1	0	4
Pruritus ani	2	0	0	0	2
Nummular eczema	1	0	1	0	2
Lichen planus	0	0	1	0	1
Pruritus hiemalis	1	0	0	0	1
Lichen simplex chronicus	1	0	0	0	1
Pemphigus vulgaris	1	0	0	0	1
Total	19	1	3	1	24

Although no determinations of serum sodium level were done, there was no instance of ankle or leg edema indicating possible systemic absorption of either the prednisolone or hydrocortisone free alcohol, even when the medicaments were applied over extensive areas of the body.

Summary and Conclusions

The clinical effectiveness of topically applied prednisolone alcohol was evaluated by the simultaneous paired comparison method in 137 patients with various selected dermatoses. Of a total of 128 patients in whom the clinical effect of prednisolone alcohol (0.5%) in water-washable base was compared with that of hydrocortisone free alcohol (1%) in the same base, the prednisolone alcohol proved to be more effective in 48 cases, the two were equally effective in 51 cases and equally ineffective in 18 cases, and the hydrocortisone free alcohol was more effective in 11 cases. Thus, in 99 out of 128 cases (77%) the prednisolone alcohol was more effective than, or equally effective as, the hydrocortisone free alcohol, although it was used in one-half the concentration of the latter. In 24 cases in which the clinical effect of prednisolone alcohol (0.5%) in water-washable base was compared with that of the empty water-washable base, the prednisolone was much more effective in 19 cases, the two were equally effective in one case and equally ineffective in 3 cases, and the prednisolone was less effective than the water-washable base in only one case. Of a total of five patients who complained of irritation from either the prednisolone alcohol or the hydrocortisone free alcohol creams, three showed allergic eczematous reactions to the empty water-washable base when applied in a closed patch test. There was no instance of an allergic sensitization to either the prednisolone alcohol or the hydrocortisone free alcohol. No evidence of undesirable side-effects from systemic absorption of the medicaments was noted.

These results indicate that prednisolone alcohol, when used in only one-half the concentration of the hydrocortisone free alcohol, is as effective as, or slightly more effective than, hydrocortisone free alcohol in the topical therapy of various dermatoses such as allergic contact dermatitis, atopic dermatitis, and pruritus ani. It would appear then that, upon topical application, prednisolone alcohol is approximately twice as effective, milligram for milligram, as hydrocortisone free alcohol. It should prove to be a most useful addition to the dermatological armamentarium.

454 New York Ave.

The prednisolone alcohol (0.5%) cream and hydrocortisone free alcohol (1%) cream used in this study were supplied as Meti-Derm and Cortifan, respectively, by the Schering Corporation, Bloomfield, N. J.

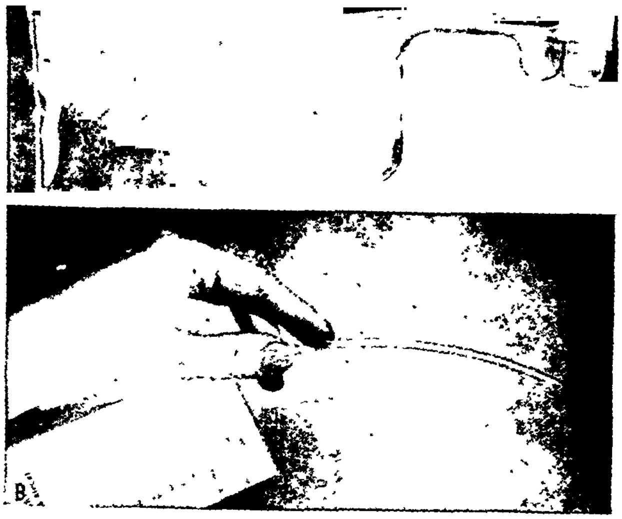
UNITIZED DISPOSABLE URETHRAL CATHETER AND SPECIMEN CONTAINER

William P. Murphy Jr., M.D., Marvin G. Flannery, M.D.
and
Donald W. Smith, M.D., Miami, Fla.

Significant laboratory examination of urine from the female requires that the specimen be collected by catheter in a clean container. Urine voided directly into a bottle or bedpan often contains foreign material, including epithelial cells, mucus, pus or blood from adjacent perineal areas, or extraneous substances from the collection container. While a negative voided specimen is significant, a positive one requires restudy of a catheterized specimen in order to determine the significance of the findings. Such duplication is time-consuming and, therefore, costly.

The method of catheterization of the bladder in the female most commonly used involves the use of a sterile rubber catheter to protect the patient from extraneous contamination, a rubber glove to handle the sterile catheter, and a suitable collection container. Each of these items must be reprocessed before each use. Since this takes time and is, from the labor standpoint, costly, and because the equipment tends to deteriorate rapidly, catheterization is sometimes neglected when it should be accomplished. This problem has stimulated us to originate a piece of equipment that will serve at a maximum saving of both time and money.

The device consists of a plastic catheter enclosed in a flexible plastic specimen container, which is sealed and sterile (see A in figure). An identification card is attached. Both unit parts are made of polyethylene because of its inert nature, relative freedom from foreign material, and smooth surface, combined with optimal stiffness and strength. After one use, both



Unitized disposable urethral catheter and specimen container, *A*, before container is opened, and *B*, ready for use.

From the Department of Surgery, Jackson Memorial Hospital.

the catheter and container may be discarded, eliminating the problems of washing, sterilization, and other intermediate handling. The catheter is suitably tipped and cut on the side to provide for adequate flow of urine without risk of traumatizing urethral surfaces during the insertion. The thin catheter wall provided by the plastic permits an outside diameter equal to that of a 12 F. catheter and a lumen equivalent to that of a 15 F. rubber catheter. This large internal diameter permits a more rapid flow of urine, useful in both specimen collection and emptying the bladder for pelvic examination. The back end of the catheter is flared making it easy to handle and express from the bag and also permitting the attachment of a syringe for bladder irrigation and aspiration.

An arm of the bag holds the tip of the catheter in place and ready for use. The bag is opened at the end containing the catheter tip by tearing a tab off, and the catheter is expressed as seen in *B* in the figure.

As the flared end of the catheter is slightly larger than the neck of the bag, the bag will not fall off. It is not necessary to wear a sterile glove to handle the catheter since it may be held by the portion remaining in the specimen container. The external meatus is prepared, the catheter inserted, and the collection bag filled. If it is desired to empty the bladder, the bag is pulled from the catheter and the remaining urine is collected in a basin. The bag is sealed by folding over the neck and fixing it to the card with the attached clip. The card has space for pertinent information identifying the patient and doctor and regarding the studies desired. It goes with the bag to the laboratory where other spaces are filled in with the results of the examination, and the entire card is returned to the physician.

We believe that a unitized sterile catheter and specimen container, of the nature described, will greatly facilitate the success of studies of urine in the female by making every specimen study a significant one and by eliminating the time and cost of equipment preparation.

25 S. E. Second Ave. (Dr. Smith).

This unitized disposable urethral catheter and specimen container is manufactured by Dade Reagents, Inc., Miami, Fla., and may be obtained under the name "Cath-Urine" from surgical supply houses.

COUNCIL ON PHARMACY AND CHEMISTRY

REPORT TO THE COUNCIL

The Council has authorized publication of the following report. Nonproprietary terminology is used for drugs that are mentioned; when such terminology is not considered to be generally well known, its initial appearance is supplemented by parenthetic insertion of names known to be applied to commercial preparations. H. D. Kautz, M.D., *Secretary.*

CURRENT STATUS OF THERAPY IN HYPERTENSION

Henry A. Schroeder, M.D.
and
H. Mitchell Perry Jr., M.D., St. Louis

Means for controlling the excessive generalized vasospasm found in patients with chronic arterial hypertension have greatly improved during the past 5 years. The development of new drugs with specific actions has pointed up the several mechanisms that act together to cause vasospasm; it has resulted in alterations toward or to normal of a disturbed physiological and biochemical state and has effected considerable reduction in morbidity and mortality and sometimes remarkable clinical improvement in patients suffering from fatal forms of the disease. Furthermore, the question of what is cause and what is effect has been clarified. The results in well-treated patients, formerly suffering from hypertension of severe degrees and often with serious secondary conditions, may be summarized as follows: a virtual disappearance of congestive heart failure, formerly the major cause of death; considerable reduction in incidence of cerebral vascular accidents, especially hemorrhage; slowing, halting, or even regression of progressive renal functional damage; and halving of the 100% mortality (for at least three years) in cases of malignant hypertension that have advanced to azotemia. In a sizable proportion of cases, the underlying process has apparently reversed itself enough to allow drastic reduction of doses or even discontinuation of therapy. Thus neurosurgery has become unnecessary except in selected cases, and other less specific forms of therapy have been made obsolete.

In order to understand the rationale for the use of the several drugs and methods, a brief résumé of present concepts of basic pathogenesis is in order. Intermittent, rapidly fluctuating generalized vasospasm is considered to be neurogenic, mediated through the sympathetic portion of the autonomic nervous system or, in the unusual case of a pheochromocytoma, by the sympathetic effector substances, levarterenol (norepinephrine) and epinephrine. Drugs are available that act upon sympathetic areas in the brain, upon autonomic ganglia, and, for diagnostic purposes, upon the sympathetic effector substances at the junction of nerve and vascular smooth muscle. Surgical sympathectomy accomplishes the same result to some degree.

Certain known and some unknown factors in time convert intermittent neurogenic vasospasm into chronic sustained vasospasm. This form is mediated by

---

From the Hypertension Division, Department of Internal Medicine, Washington University School of Medicine, and Barnes Hospital.

humoral, probably nephrogenic, vasoconstrictor substances. A different type of drug, acting directly upon vascular smooth muscle, is available to counteract this influence. The drug also has the capacity to destroy the activities of most known and suspected humoral pressor substances implicated in hypertension. When hypertension becomes chronic, therefore, both humoral (nephrogenic) and neurogenic influences operate together, the former engrafted upon the latter. Renal ischemia is the invariable accompaniment.

In certain cases of overt localized disease of the adrenal cortex (adenoma), and perhaps to a slight degree in many other cases of hypertension, vascular smooth muscle becomes sensitized both to normal and to abnormal vasoconstrictor influences, neurogenic and humoral. Sensitization is mediated through the sodium ion plus sodium-retaining steroid hormones. Overproduction of adrenal cortical salt-retaining hormones can probably affect intracellular constituents of electrolytes. In the ratio $Na^+ + K^+ + OH^-/Mg^{++} + Ca^{++} + H^+$ muscular irritability is increased by an increase in the numerator and decreased by an increase in the denominator. Because renal ischemia even of a slight degree is associated with urinary loss of sodium chloride, presumably the adrenal cortex is stimulated to produce more salt-retaining steroids than usual. Methods for counteracting this influence include adrenalectomy, metabolic antagonists to specific steroid hormones, and depletion of sodium from the body. This influence is usually of secondary pathogenetic importance except when functioning adenomas are present, when it can be primary. Thus it is obvious that when two vasospastic influences act together to cause hypertension, two counteracting drugs or methods must be used to achieve reversal of vasospasm.

Drugs and Procedures Available

Drugs Acting Directly or Indirectly on Central Sympathetic Areas.—Alkaloids from species of Rauwolfia, of which reserpine is one, act on cerebral centers. Reserpine, a very mild antihypertensive agent, acts by displacing serotonin from receptors in corticohypothalamic tracts, especially those to the posterior (sympathetic) portion of the hypothalamus. Although the drug is rapidly excreted, these receptors are blocked for several days. The result is a reduction of the sympathetic outflow and relative parasympathetic overactivity; therefore, nervous reactions to stress by vasospasm are partly inhibited. This drug also releases serotonin from platelets and the intestines. Its usual side-effects are many and frequent. Those resulting from parasympathetic overactivity are bradycardia, gastric hyperacidity, and gastrointestinal hypermotility (peptic ulcer has apparently been activated and ulcerative colitis initiated by reserpine). Those probably resulting from serotonin depletion are loss of affect, drive, ambition, and the ability to form new concepts and meet new situations (effects similar to those of a medical prefrontal lobotomy). Increased appetite and decreased nervous energy may lead to obesity, and nasal stuffiness has occasionally caused epistaxis in older individuals with atherosclerotic arteries. More serious late side-effects, possibly caused by excessive depletion of serotonin, are anxiety, nervousness, insomnia, and wild dreams and nightmares; eventually, agitated depressive psychosis with suicidal tendencies may occur, which places it among the drugs with occasional fatal reactions. Return of function after a psychosis has developed may be delayed for several weeks or months.

The dosage-response curve to reserpine is extremely flat; therefore, large initial doses (1 to 4 mg.) can be given safely. The mild hypotensive effect precludes any exact statement as to optimal dosage, although frequently a dose of 0.1 to 0.25 mg. is satisfactory for maintenance. Since some effect usually persists for weeks, a single daily oral dose is adequate. Normotension is usually achieved by this agent only in the mildest cases with considerable emotional overlay.

Chlorpromazine (Thorazine) is also a serotonin antagonist, although its primary action is not to paralyze cerebral serotonin receptors but rather to affect the vasomotor center in some manner. Large doses produce not only bradycardia and a slight to moderate fall of blood pressure but also many side-effects. Thus it is of little value as an antihypertensive agent other than indirectly through its sedative action.

Protoveratrines A and B (Veralba), two alkaloids extracted from species of Veratrum, act at a similar or lower level by stimulating the carotid sinus and aortic depressor nerves (the baroreceptors), thus causing an increase in their depressor activity. The pathway is through the glossopharyngeal nerve to the vasomotor center. Side-effects caused by vagal stimulation include bradycardia, increased gastrointestinal motility, gastric hyperacidity, nausea, and vomiting. Intermittent hypotension or normotension can be achieved only by careful regulation of dose, which varies from one individual to another.

The initial dose of protoveratrines A and B, most satisfactory when given orally, is 0.5 mg. three times a day. This dose is increased by increments until the desired effect is produced or nausea supervenes. Ordinarily the margin of safety between therapeutic and toxic doses is low, making dosage critical. The very rapid appearance of tolerance precludes the maintenance of normotension with this agent alone.

Drugs Acting to Interrupt Somatic Autonomic Nerves.—Of the four drugs most commonly used clinically to interrupt somatic autonomic nerves, one is a secondary amine and three contain tetracovalent nitrogen (quaternary ammonium) as does acetylcholine. Special configurations in the molecules apparently cause predilections for autonomic ganglia, just as other configurations of tetracovalent nitrogen promote acetylcholine inhibition at myelinated nerve endings on striated muscle (curare, succinylcholine, decamethonium, and other curariform drugs).

The four orally effective blocking agents are hexamethonium, pentolinium (Ansolysen), chlorisondamine (Ecolid), and mecamylamine (Inversine). The amine, mecamylamine, is entirely absorbed from the gastrointestinal tract, while the three quaternary ammonium drugs are absorbed to varying and unpredictable extents. All have similar clinical effects and durations of action. No evident metabolism has been shown for any of them, and all are excreted by the kidney. Potentiation of autonomic blockade results from gastrointestinal hypomotility, which allows increased absorption; renal failure, which delays excretion; and diminished intake of sodium. Tolerance is characteristic of blocking agents when they are used alone. Moreover, the danger of postural hypotension ordinarily precludes lowering the blood pressure to normal in any but the erect position, with the result that some authorities insist on the patient sleeping on an incline with the head up. Both tolerance and postural hypotension usually may be prevented by simultaneously administered hydralazine (Apresoline).

The pharmacological effect of autonomic blocking agents is that of both sympatholysis and parasympatholysis. The desired antihypertensive effect results from sympatholysis. Excessive hypotension may rarely lead to renal failure requiring levarterenol (Levophed) for its control. Undesired side-effects result from parasympatholysis; the major ones are retention of urine and intestinal paralysis. The minor ones include loss of visual accommodation, dryness of mucous membranes, and diminution of normal sweating.

The required dose of autonomic blocking agents is unpredictable and must be determined separately for each patient. The effect can often be enhanced and rendered more reproducible if these drugs are taken on an empty stomach. Orally mecamylamine is about 50 times as effective as hexamethonium, 10 times as effective as pentolinium, and 5 times as effective as chlorisondamine. For each the duration of action of a single dose varies between 3 and 6 hours, hexamethonium being the shortest acting and chlorisondamine and mecamylamine having the longest effect. The wide variety of advocated regimens reflects the differing goals of therapy as well as the variability of individual patients.

The autonomic blocking agents can be used parenterally in hypertensive emergencies such as encephalopathy and cardiac failure. Even when injected, the required dose is unpredictable. In general, the more acutely a patient requires therapy, the less drug he needs. The maximum safe initial dose of hexamethonium chloride, given subcutaneously or intramuscularly, may be as little as 0.25 mg. Larger doses can be given into an extremity when a tourniquet can be placed above the site of injection, or by slow intravenous drip, the blood pressure being "titrated" to the desired level. If circulation is adequate, doses given subcutaneously can safely be successively doubled at 10-minute intervals until sufficient lowering of the blood pressure is obtained. To maintain normotension, as much as 25 or 50 mg. of hexamethonium given subcutaneously may be needed every 4 hours. When necessary the systolic pressure can often be maintained within a range of 20 mm. Hg by parenterally given autonomic blocking agents. In our experience, this can best be done by giving a full dose every 1, 2, or 4 hours if the systolic pressure is above the desired range, half the dose if it is within the range, and none if it is below the range. The mean pressure can then be lowered on successive days depending on the patient's condition. In those rare cases in which gastrointestinal symptoms require substitution of long-continued parenteral therapy, the average maintenance dose of intramuscular hexamethonium approximates one-twentieth of that required by mouth. For pentolinium the parenteral dose approximates one-fifth of the oral dose; for chlorisondamine, two-fifths; and for mecamylamine, the two are equal.

When localized atherosclerosis is present, the violent fluctuations of blood pressure sometimes induced by drugs can be hazardous. Ischemia may result either from a lowered blood pressure in vessels that cannot dilate as widely as the remainder of the vascular system or from thrombosis beginning on an atherosclerotic plaque when blood flow is impaired. Thus, cerebral thrombosis, mesenteric thrombosis, and coronary thrombosis have occurred rarely and must be kept in mind when atherosclerotic patients are treated. Ischemia has also caused depression, temporary loss of memory, worsening of anginal pain (rare), and temporary diminution of renal function (not to the extent of azotemia, however).

In the small and very seriously ill group of patients with true malignant hypertension that has progressed to the point of azotemia, hexamethonium has produced a fatal pulmonary disease characterized by fibrinous pneumonitis. Hexamethonium is the only autonomic blocking agent associated with this type of toxicity; moreover, the entity has become rare in the last 2 or 3 years, perhaps because other ganglionic blocking agents are more popular and control of hypertension is better achieved. Poor and intermittent control of hypertension has usually preceded pulmonary symptoms. Tachypnea, becoming worse in the sitting or standing position, is a cardinal sign. The microscopic lesions resemble those of "uremic pneumonia" despite the presence of only moderate azotemia (no more than 60 mg. of nonprotein nitrogen per 100 ml. of plasma) and the absence of clinical uremia. One patient may have recovered after treatment with cortisone.

In this same small group of very seriously ill patients with true malignant hypertension that has progressed to the point of azotemia, large doses of mecamylamine have produced a nonfatal, reversible disturbance characterized by generalized and severe coarse or flapping tremor that disappeared with sleep. Intense anxiety, sometimes with hallucinations, has also occurred. The syndrome resembles delirium tremens rather than Parkinsonism. Recovery has taken as long as 1 to 2 weeks after withdrawal of the drug and substitution of another agent.

Drugs Acting Directly on Vascular Smooth Muscle.—Hydralazine relaxes constricted vascular smooth muscle. Notable among its effects is an increase in renal plasma flow, reversing the hemodynamic profile accompanying hypertension. It is unique in that this action is duplicated only by pyrogens and pregnancy. Another important effect includes inactivation of pherentasin, the vasopressor polypeptide found in human hypertensive blood, and inactivation of hypertensin or angiotonin, the vasopressor polypeptide resulting from the proteolysis of a plasma globulin by renin from the kidney. It is likely that pherentasin is activated human angiotonin. In vitro, hydralazine inhibits at least one decarboxylase, that of dihydroxyphenylalanine, and stimulates monamine oxidase, the ubiquitous enzyme that can deaminate many substances with vascular and cerebral actions such as hypertensin, pherentasin, serotonin, levarterenol, epinephrine, tyramine, and tryptamine. Some of these are the products of amino acid decarboxylation. Hydralazine is also a strong chelating agent for some trace metals. In these respects its actions on the humoral nephrogenic mechanisms of hypertension are ideal, as it causes vasodilatation, increased renal blood flow, and both diminished production and increased destruction of vasoactive substances found or suspected in blood. Hydralazine should therefore be a basic medicament in all forms of the disease in which a nephrogenic, humoral influence is present. It must be given in large doses to patients in whom this influence is great.

There are unwanted and undesirable actions of the drug. Histaminase is inhibited in vitro; some of the symptoms that appear when hydralazine is given, including headache, flushing, aching, edema of the skin, and nasal stuffiness, may be attributed to failure of destruction of histamine. Mild chemosis is common; tachycardia is produced, but it may be inhibited by drugs given adjunctively that act on the nerves. Occasionally drug sensitivity with fever, aching, and flulike symptoms appears. In a few individuals the drug cannot be used at all.

Late toxic reactions generally are confined to a syndrome simulating disseminated lupus erythematosus, characterized usually by arthritis or arthralgia in the early stages, with malaise, lassitude, and weakness. Splenomegaly, hepatomegaly, and lymphadenopathy are sometimes seen; evidence of disturbance of circulating protein levels is almost always found, with increased cephalin cholesterol flocculation and thymol turbidity of serum and hyperglobulinemia. Leukopenia and anemia have been seen and the L. E.-cell preparation of blood eventually becomes positive. If administration of the drug is discontinued, these symptoms and findings regress and disappear; if not, symptoms may subside only to recur. The main organic change is progressive renal dysfunction with azotemia, which does not, in our experience, regress or progress after the drug has been omitted. This syndrome has been reproduced in dogs, with the appearance of "wire-loop" lesions of glomeruli. "Hydralazine disease," which occurs in 8 to 10% of individuals, is rarely seen in patients taking 0.4 gm. a day or less. It develops in 5 months to 4 years, cannot be made to develop deliberately by very high doses, and is completely, if slowly, reversible when administration is discontinued. The phenomenon resembles a syndrome of depletion in many respects and one of hypersensitivity in others. By reducing the dosage slowly and carefully after 6 months of therapy to 0.4 gm. a day or less, this high rate of reaction can be lowered. By no means does it negate the use of this valuable drug. Furthermore, it stimulates research and development of analogous substances, among which are many experimental compounds that chelate or bind trace metals. Thiocyanate, nitroprusside, azides, and dimercaprol (BAL) have been used in man; many other binding agents have been tried in hypertensive animals. Other compounds that act on constricted vascular smooth muscle and destroy hypertensin and pherentasin but are less toxic are sorely needed.

Agents and Methods Affecting Vascular Smooth Muscle by Interfering with Salt-Steroid Relationships.—No drugs are available as yet that will compete with aldosterone (11β-21-dihydroxy-3,20-diketo-4-pregnene-18-al) or other salt-retaining hormones and therefore depress the reactivity of vascular smooth muscle; however, experimental agents that will do this have been synthesized. Until specific antialdosterones are found, the only recourse is dietary restriction of sodium. The restriction must be strict and considerable, to 0.5 gm. of salt per day, a regimen difficult to achieve for the average patient.

The physician should understand what he is doing when salt is restricted. The kidney of a patient with hypertension, even in the mildest stages, loses salt. The effect of salt restriction is to cause overactivity of the zona glomerulosa of the adrenal cortex. The expected result is excessive production of aldosterone, just as this hormone is produced in salt-retention states such as edema. Because salt-retaining hormones plus sodium ion apparently sensitize vascular smooth muscle to vasoconstrictor substances and impulses, removal of either may negate excessive sensitivity, but removal of sodium may cause overproduction of the other. Too severe salt depletion will lead to the low-salt syndrome, with renal insufficiency and death. Thus salt restriction of a degree sufficient to lessen vascular reactivity must be carefully achieved in order to avoid both insufficient and excessive loss of sodium. The relatively few fatal reactions observed indicate that the error is largely on the side of insufficient depletion.

Methods of Administration

The use of potent hypotensive agents cannot be haphazard, intermittent, or careless. There is no better method for producing intractable tolerance to their actions in severe hypertension than by discontinuous, uneven therapeutic pressure. Once started, they must be given at regular intervals, in doses adequate to produce the desired effects. Side-effects are treated as they arise; with ganglionic blocking agents they are averted before they appear by the use of laxatives and parasympathomimetic drugs.

The aim of therapy is to cause mean diastolic normotension or, failing that, a reasonable facsimile thereof. Compromises with normotension result in compromises with the disease. The upper limit of diastolic normotension is defined as 90 mm. Hg. To achieve it requires education of the patient, a physician familiar with the pharmacological actions of various drugs, duration of action and side-effects, and careful instruction in self-medication. It also requires data on levels of blood pressure, secondary effects of the disease, and progress of the patient. Failing that, control is erratic and hazardous. No attempt is made to achieve systolic normotension (140 mm. Hg) in patients with severely atherosclerotic aortas.

The *sine qua non* of effective therapy of chronic generalized vasospasm is to use one agent acting on neurogenic vasoconstrictor mechanisms and one agent acting on vascular smooth muscle. No single drug combines these two actions.

Milder forms of the disease respond to milder measures, more severe forms to more potent drugs and vigorous measures. Unfortunately, the durations of action of all of the orally effective available ganglionic blocking agents are short, 4 to 6 hours, and they must be given at these intervals. When one of the hypertensive mechanisms, either the neurogenic or nephrogenic, is blocked, the other appears to "overshoot" or become hyperactive. Thus, in severe cases, and even in less severe ones, both types of agents are essential for control.

In milder cases, when hypertension is present upon examination by a physician and during emotional stress but is probably absent during sleep and relaxation, reserpine alone, 0.1 to 0.5 mg. given orally per day, may be tried for a month or two. If this is not effective, hydralazine hydrochloride is added in doses of 25 mg. four times a day, increasing at weekly intervals until 300 or 400 mg. per day is given. The maximal effect can be observed in one to three months. This method is justifiable only when the physician is relatively certain that a cardiovascular accident will not occur in that interval or that renal deterioration is not present and progressive. A false sense of security may be engendered by the very fact of treatment, even though treatment is inadequate or useless.

In more severe cases, those in which hypertension does not respond completely to sedation, relaxation, bed-rest, or sleep induced by amobarbital (Amytal) sodium, or in patients with persistent hypertension leading to cardiovascular accidents, ganglionic blockade and hydralazine are indicated. Ganglionic blockade is initiated more safely and easily in the hospital.

Blood pressure is measured by competent nurses every 4 hours, day and night, and charted. The choice of a ganglionic blocking agent is a matter of individual preference. Hexamethonium chloride (125 mg.), pentolinium tartrate (20 mg.), chlorisondamine chloride (12.5 mg.), or mecamylamine hydrochloride (2.5 mg.) are given orally every 4 hours around the clock. In order to avoid undue intermittent hypotension, doses are omitted if the systolic pressure is below a chosen level, usually 140 mm. Hg for younger individuals and 150 or 160 mm. Hg for those with atherosclerosis of the aorta, cerebral thrombosis, or ischemic manifestations caused by local atherosclerosis. Some physicians take the blood pressure with the patient supine, whereas others take advantage of postural effects and measure it with the patient seated. Measurement with the patient in the standing position should be avoided, for falsely low values and insufficient doses will result. Laxatives should be given as needed to prevent constipation and the consequent danger of paralytic ileus in patients receiving ganglionic blocking agents by mouth.

The dose of ganglionic blocking agent is raised every day by increments similar to the initial dose until fluctuations to normotensive pressures occur. In the usual case of moderately severe hypertension, 500 mg. of hexamethonium chloride, 100 mg. of pentolinium tartrate, 50 mg. of chlorisondamine chloride, or 10 mg. of mecamylamine hydrochloride every 4 hours is sufficient to produce this effect, although twice these doses occasionally becomes necessary. Rarely is normotension (mean pressure, 140/90 mm. Hg or below) achieved and maintained by these drugs when used alone, partly because of irregular absorption, rapid elimination, and increasing tolerance.

If protoveratrines A and B are preferable, an initial dose of 0.5 mg. is given three or four times daily during the day and increased daily by 0.5 mg. at first and then by 0.2 mg. until nausea or vomiting occur. The dose is then reduced by 0.2 mg. Patients vary considerably in their reactions to this agent; since there is some carry-over from one dose to another during the day, the morning dose will be relatively high (2 mg. or more), the noon dose less (1 mg.), and the evening dose greater or less. The production of fluctuations to normotensive levels at doses less than those causing nausea is the aim; each dose is critical in this respect.

At this point 25 mg. of hydralazine hydrochloride is administered every 4 hours. At daily intervals this dose is successively doubled, tripled, and finally quadrupled. If normotension is not achieved, the dose of blocking agent or hydralazine is increased, depending upon clinical judgment and findings as to whether neurogenic or nephrogenic influences are greater. In unusual cases of sensitivity, this drug cannot be used. During the appearance of sustained normotension or considerable fall in blood pressure, the patient often complains of weakness, lethargy, lassitude, prostration, and poor memory. He then needs encouragement, for these symptoms pass in a few days or weeks.

Before the patient leaves the hospital, the night dose is omitted and blood pressure is measured always with the patient sitting. Doses of blocking agents automatically adjust themselves downward by this procedure, although higher levels are usually found in the morning because the agent is excreted during the night. The patient is taught to take and record his own pressure and is discharged from the hospital to continue on five doses of blocking agent and hydralazine per day, the former on a sliding scale depending upon prevailing levels of systolic pressure. The effective dosage of ganglionic blocking agents is usually less during warm weather. The rationale and limits of therapy are carefully explained. In our experience, only rarely is a patient made nervous or neurotic by self-medication and self-measurement; on the contrary, a sense of relief and freedom from anxiety is provided him by learning that he can lower his blood pressure by a tablet.

If data are adequate (frequent readings of blood pressure) and suggest a reduced drug requirement, after 6 months of therapy in some cases and after a year in others, the doses may be decreased to four times a day. A rise in the mean pressure level during the next week or two requires readjustment of the dose upward. After 2 or 3 years, especially when little ganglionic blocking agent is needed, the amount of hydralazine hydrochloride may be lowered slowly to very small quantities, 25 mg. per day, or even omitted. If, however, diastolic normotension is not achieved, no reduction in dosages is advisable.

Withdrawal of both drugs, unless by gradual decrements as described, results in a return of hypertension. If the patient formerly exhibited the malignant stage (hemorrhagic and exudative retinitis, papilledema, high fixed diastolic pressure, and renal damage), that stage may return abruptly in a day or two, with subsequent deterioration and death resulting from a cerebral vascular accident or an episode of congestive heart failure. If a patient is once committed to therapy, therefore, he should continue until it no longer becomes necessary. Whether or when that time will arrive cannot be foretold.

There are alternate choices of combinations of these drugs and methods, suitable for individual cases. Ordinarily, none of these drugs will give an optimal result when used alone; however, a drug or measure acting on autonomic nerves can be combined with one acting on vascular smooth muscle with additive results. Thus, reserpine, surgical sympathectomy, or ganglionic blockade can be satisfactorily added either to dietary restriction of salt or to hydralazine. In our experience, the combination of two measures in the first group provides erratic control, while the combination of two in the second is little more effective than either one alone.

The potencies of the different drugs and combinations of drugs in counteracting generalized vasospasm can be expressed briefly as follows from mildest to strongest: reserpine, reserpine plus hydralazine, protoveratrines A and B, chemical ganglionic blockade, protoveratrines A and B plus hydralazine, and ganglionic blockade plus hydralazine. If a strict low-sodium diet (0.5 gm. of sodium chloride per day) can be attained, its effect can be considered approximately equal to that of hydralazine alone; therefore, it may be substituted for hydralazine in any one of the previously mentioned combinations. Hydralazine alone is seldom given unless surgical sympathectomy has been performed.

From the foregoing data, it is obvious that the use of a single capsule or tablet containing a combination of two or more potent agents is unduly restricting and may even be hazardous. Each type of drug acts upon a different area, and the dose must be adjusted to suit the individual. Regarding side-effects of ganglionic blockade, this is one of the rare examples in which one is justified in setting one pharmacological thief to catch another; however, a blocking agent combined with a standard dose of neostigmine (Prostigmin) or bethanechol (Urecholine), for example, given in varying doses, might be expected to cause unpredictable results. These combinations of two oppositely acting drugs are avoided. Furthermore, there is no more justification for giving reserpine, a drug with prolonged action, in slowly released doses from a capsule, than there is in giving digitalis in such a preparation. Each agent is given for its specific action in the dose that will produce the desired effect without undue toxic effect.

Summary

Modern drugs and methods provide a relatively safe and effective, though difficult, form of therapy for combating the excessive vasospasm to which arterial hypertension is secondary. Undesirable side-effects are common to all. If the drugs are to be used to their best advantage, a physician familiar with their primary actions and side-actions and a patient educated in their use are essential. Prolongation of life, lessening of cardiovascular-renal accidents and deterioration, and regression of the basic disease have been demonstrated. No patient need live with hypertension if he is willing to endure the inconveniences of therapy.

COUNCIL ON INDUSTRIAL HEALTH

The following Committee Report was approved for publication by the Council on Industrial Health on Oct. 27, 1956. B. Dixon Holland, M.D., *Secretary.*

THE SURVEY OF THE OCCUPATIONAL ENVIRONMENT

AN ESSENTIAL OF INDUSTRIAL MEDICAL PRACTICE

Introduction

This treatise is intended primarily for those physicians who serve industry on call; those physicians whose private clientele includes industrial employees; and those to whom industrial employees come for preplacement, periodic, or other types of physical examination, diagnosis, or treatment. Its purpose is to promote greater interest, knowledge, and activity in occupational health on the part of all physicians who are, or should be, concerned. Full-time industrial medical directors and staff physicians presumably are well acquainted with the matters discussed, as are most physicians occupying such positions part time. However, they might find in this treatise worthwhile reminders.

The physician may gain much through a personal survey of the occupational environment of persons who are under his supervision or of those who are or may become his patients. Increasingly in the large plant and especially where there is a well-organized medical department, the industrial physician observes operations and the conditions under which the employees are working. This practice should be adopted by the physician who has an "on-call" relationship with industrial plants. After each survey, the physician should discuss his observations with management with particular recognition of the fact that the assistance of several disciplines is usually necessary to control a given situation.

General practitioners whose patients include industrial workers can and should acquire some knowledge of the industrial operations of the area through organized plant tours or invitational open-house arrangements between the industries and the local medical society.

Manifold advantages are to be gained from a survey of the occupational environment. The information obtained may permit the physician more adequately to diagnose and treat disease affecting his patient. As an example, a persistent hepatitis may fail to respond to treatment. Inquiry into the patient's occupation may disclose exposure to a chlorinated hydrocarbon solvent vapor as the possible cause. Only after this exposure is evaluated and brought under satisfactory control

---

This report was prepared by the subcommittee to revise "Plant Hygiene Studies" of the Committee on Interprofessional Relations, Council on Industrial Health, American Medical Association. The following persons are the members of the subcommittee: Warren A. Cook, Chairman, William G. Hazard, Herbert T. Walworth, Irving R. Tabershaw, M.D., and Jerome K. Brasch.

can the patient's hepatitis be alleviated and, of equal importance, development of hepatitis in other workers at the operation be avoided.

Similarly, the survey permits the physician to become familiar with the physical and mental demands of the job. It gives him the opportunity to see the people at work, in circumstances in which they are much more likely to be at ease than in his office. In addition he can become acquainted with materials and operations, the nature of exposure to substances and conditions that may affect health, and the physical conditions that may be the cause of accidents. It is important, however, at this point to caution the physician against hasty and unsubstantiated conclusions.

The physician is thus in better position to help in matching the physical abilities of a prospective employee with job requirements. He has a better understanding of the industrial health hazards as they actually exist in a given plant and at a specific operation. This knowledge of the environment permits him to take a more effective part in the prevention of occupational diseases and in accident prevention. What then is the first approach in making an initial survey of a plant and what should be looked for?

Preliminary to the Survey

Arrangements for an initial plant survey should be made invariably with management or an appropriate representative of management. Where the plant is small, there should be a discussion of the purposes of the survey with the head of the concern and the physician serving the plant. If the plant is a division of a larger organization, inquiry should be made through local management as to whether there is a medical director or consultant who supervises occupational health throughout all plants. If so, the physician should communicate with him. Both management and medical advisors would be expected to welcome such interest in plant conditions on the part of a general practitioner or on-call physician. In preparation for the survey, the physician should acquaint himself with the workmen's compensation act and the industrial health and safety regulations of the state.

In the actual conduct of the survey, management should designate someone familiar with the plant to accompany the physician through the various departments. In the larger concerns the safety director or the industrial hygienist would be the logical selection, since he would be well informed as to operations and potentially hazardous conditions, and as to the means of safeguarding workers against them. Prior to making the trip through the plant, the physician should discuss conditions with the person who is to accompany him.

A review of plant dispensary records should be made with special reference to minor complaints and injuries as well as lost-time injuries. It is to be hoped that there may have been some analysis of these data relative to major causes of injury, preferably in accordance with the code of the American Standards Association.[1] Special note should be taken of symptoms or complaints reported, particularly if recurrent in the same person or in different persons in the same department. If periodic physical examinations have been made, positive findings that may be associated with occupation help to point out those operations especially to be noted in the survey.

The Survey

Several types of surveys that vary in their purposes and thoroughness are well discussed by Patty.[2] He not only notes the information that should be gained in these surveys but also includes pertinent comments on proper conduct within the plant on the part of the person making the survey.

Conditions to be watched for are described briefly in the following paragraphs. Where such conditions are found, the physician should become more completely informed through references such as are listed by the Council on Industrial Health of the American Medical Association.[3]

POTENTIAL HEALTH HAZARDS

Injurious Materials

Dusts (Pneumoconiosis).—The hazard presented by dust in an occupational environment is dependent on a number of factors. It is necessary first to know something of its composition. Abrasive blasting may involve free silica in the form of quartz if a flint or sand abrasive is used. In this case, the dust exposure of the worker must be kept at a low level if silicosis is to be avoided. On the other hand, where steel abrasive is used to remove scale from steel forgings, the dust contains no silica and consequently need not be kept under as meticulous control as in the former instance.

The maximum amount of dust that can be considered acceptable depends not only on its composition but also on its particle size and the duration of exposure. Generally, dusts present in work atmospheres include appreciable proportions sufficiently small to reach the alveoli. The exceptions are rare. In regard to duration of exposure (not only to dusts but to other hazardous materials), an operation may be observed to be brief, but inquiry should be made as to whether it is repeated during the day, and how often. Where production involves a number of diverse operations, it is well to inquire whether activity at other periods during the day or week may involve exposures greater than those observed.

The dusts most likely to produce disabling pulmonary involvement are those containing free silica, that is, silicon dioxide not chemically combined with other elements. Such dusts occur frequently in industry. Inquiry should be specific in regard to this component, especially since the presence of free silica may not be readily apparent. For example, soapstone powder, widely used to keep layers of unvulcanized rubber from sticking together, may contain from 0 to 17% of free silica, depending on its source. The most common form of free silica is quartz, which occurs widely in nature. Natural materials widely used in industry that should be regarded as potentially productive of silicosis because of their high free-silica content are granite, flint, sandstone, sand, tripoli, and diatomaceous earth.

Dusts containing asbestos should also be noted, because prolonged exposure to asbestos dust in excessive concentration may result in a type of pneumoconiosis known as absestosis, which may be disabling. In coal mining and handling, attention should be given to the possible development of coal workers' pneumoconiosis, a recently recognized but incompletely explored clinical condition due to exposure to coal dust, per se, as well as to the possibility of silicosis from exposure to free silica in the rock associated with the coal in certain areas.

Metals and Their Compounds.—A large number of metals and their compounds are used throughout industry. As a potential industrial health hazard, the most prominent of these is lead, which may be present alone or in a wide variety of compounds. The chief mode of entry is inhalation of dust or fume. Percutaneous absorption of metallic lead and inorganic lead compounds is insignificant, but tetraethly lead and a few other organic compounds of lead may be absorbed through the skin under suitable conditions. Molten lead ordinarily does not present a hazard unless its temperature is well above its melting point. Special attention should be given to operations where lead may be subjected to temperatures above its boiling point, as in the welding of leaded steel. It is wise to have persons who work regularly with lead checked periodically for the extent of their lead absorption by determination of lead in blood or urine.

Lead compounds may be known by a number of names not including the word lead. Litharge, the common name for one of the oxides of lead, is found in the paste of lead storage battery plates, in a cement for attaching glass to metal, in "doctor" solution in petroleum refining, and in the manufacture of chrome yellow pigment. Although the specific gravity of this compound is high, litharge is often so fine that when dispersed into the atmosphere it will persist long enough to cause excessive exposure if adequate control measures are not in effect. In most industrial operations where dusty lead compounds are used or produced, it is desirable to have an evaluation of the exposure made with the aid of laboratory analysis of the air or of samples of the blood or urine of exposed employees, or by the combined investigation of the environment and the personnel.

Other toxic metals to which the physician should be particularly alert include antimony, arsenic, beryllium, cadmium, cobalt, manganese, mercury, and phosphorus. Exposure may occur in mining, metal-refining, fabrication, and metal-cleaning operations. Welding or high-temperature cutting on cadmium-plated surfaces can be particularly hazardous. The toxicity of beryllium is so extreme that it is in a category of its own. Mercury is of special importance because hazardous concentrations of vapor are released from the liquid metal even at room temperature. The dust of various mercury compounds is also toxic. Chromium in the form of chromic acid mist is commonly found in chromium electroplating or as salts of chromic acid in the form of dust, and may cause ulceration of the skin or the nasal septum. Zinc in the form of fresh zinc oxide fume, such as may arise from a bath of molten zinc at a galvanizing operation, may cause the temporarily disabling illness known as metal fume fever.

Excessive exposure to iron dust or fume as produced in welding, gas cutting, or grinding may cause sufficient retention in the lung to show as nodulation on chest films, but the condition is not regarded as disabling. These changes are somewhat erroneously interpreted as silicosis.

Whereas the pneumoconiosis-producing dusts usually require prolonged periods of exposure (years) to produce their effects, very brief exposures to toxic metals, solvent vapors, and gases can cause illness. Thus it is important that the physician be alert to the possibility that operations of brief duration may entail exposures more severe than those observed at the time of his survey.

Solvents.—In observing operations involving solvents, the physician should consider the possibility of absorption through the skin, in addition to absorption through the respiratory tract. Contact of these materials with the skin not only provides an avenue of introduction into the body but also presents the possibility of dermatitis.

There is a wide range of hazard potential among the many solvents used in industry. This is governed by the volatility of the solvent as well as by its toxicity. The exact chemical name of the solvent should be obtained. This need is illustrated by the two solvents, tetrachloroethylene and tetrachloroethane. There is only a slight difference in their names, but the toxicity of the former is indicated by a maximum acceptable concentration in the atmosphere of 200 parts per million as against 5 ppm for the latter—and they are of essentially the same volatility.

One of the frequent uses of solvents in a great variety of plants is in equipment known as the vapor degreaser. This is essentially a tank in which a solvent, often trichloroethylene, is vaporized by heating, and metal parts to be degreased are placed in the hot vapor. Such equipment can be used without excessive exposure to the operator, but a considerable number of poor practices, as listed by Horowitz,[4] can result in exposure beyond the recommended limit. Benzol (benzene), carbon tetrachloride, carbon disulfide, and methanol are other industrial solvents that may cause serious illness if not used under properly controlled conditions.

Gases.—In general, potenially hazardous exposure to gases is not obvious in occupational environments. For example, a visit to a gasoline engine test room may fail to indicate the presence of a moderate carbon monoxide hazard. Where carbon monoxide may occur by leakage from a pipe line, or by impingement of a gas flame upon a cold surface with resultant incomplete combustion, or by its use as a reducing gas in a heat-treating department, inquiry should be made into the occurrence of headache among the employees such as would result from moderately elevated concentrations over a number of hours or throughout the day. In addition, the possibility of accidental liberation of high concentrations that may result in asphyxiation should be kept in mind.

These two elements of hazard apply to exposure to a number of other gases. The more prominent symptom from moderately excessive exposure to hydrogen sulfide is irritation of the eye rather than headache, but the danger of rapid asphyxiation is even greater than that from carbon monoxide. Experience has shown that the odor of hydrogen sulfide is no safeguard against excessive exposure, because even brief exposure to sufficiently high concentration results in the loss of the ability to smell this gas.

A number of gases are brought into plants in cylinders in the form of liquids under pressure. These include hydrogen fluoride, used in certain oil-refining processes and in the chemical industry; hydrogen cyanide and methyl bromide, both used for fumigation and for other purposes; and chlorine, widely used for bleaching, in water treatment, and as a bactericide. Other toxic gases include ozone, nitrogen dioxide, and sulphur dioxide.

Dermatitis-Producing Materials.—The phase of the survey dealing with dematitis-producing materials may best start with the industrial nurse who probably will be well informed of the incidence of dermatoses. For example, if no cases from cutting oils and compounds have come to her attention, this source of dermatoses may require no further investigation, but, if numbers of minor cases with an occasional serious case have occurred, this situation should be thoroughly investigated. Attention should be given to washing facilities, soaps and cleansers used, and the availability of hot water. Personal washing procedures as well as other measures such as protective creams and equipment should also be checked.

In addition to solvents, innumerable other primary irritants and sensitizers cause skin affections. Wherever there is skin contact with primary irritants, which may include not only strong acids and alkalis in an electroplating department but even dishwater in a plant cafeteria, there may be some incidence of dermatitis. Skin contact with such materials should of course be avoided, though this is difficult in some operations.

Among the many sensitizers, exposure to those involved in the preparation of synthetic resins and in the manufacture of plastics is worthy of note. The effect on the skin may be caused by contact either with dust or with gases liberated during these processes.

Where waxes are used for impregnation of electric condensers or for wire and cable insulation, inquiry should be made as to whether these are chlorinated naphthalene or diphenyl compounds. If so, suitable precautions (often listed by the producer) should be followed.

Pathogenic Micro-Organisms.—A number of occupations involve exposure to pathogenic micro-organisms, through their incidental introduction into lacerations. In packing houses, measures to avoid brucellosis and psittacosis should be noted. In plants that handle imported animal products, such as hair, bristles, wool, and hides, investigation should be made of the need for sterilization of these materials and, if in order, the method used. Workmen in these plants should be told what an anthrax pustule looks like and impressed with the need for immediate medical attention for such a lesion.

Other Materials.—Materials other than those falling within the foregoing classifications should not be overlooked. Examples of such materials are those capable of inducing cancers, including chromium compounds (lung) beta-naphthylamine and benzidine (urinary bladder), and certain polycyclic hydrocarbons that may be present in coal tars and in certain high-boiling catalytically cracked oils (skin). Surveys of industrial exposure to the cancerogens should be supplemented by epidemiological investigations. A single case of cancer hardly proves a cause-and-effect relationship where exposure to a suspected cancerogen is involved, but incidence of such cases significantly in excess of that occurring in the general population would point to the occupational exposure as a possible cause.

Hazardous Conditions

In addition to hazardous materials, observations should include hazardous conditions. These may be covered under the following headings.

Excessive Noise.—Exposure, particularly of long duration, to excessive noise levels may cause diminished acuity of hearing. Although sufficient data are not yet available on which to specify a precise level of sound of a given frequency that can be taken as a maximum acceptable level, certainly those noise conditions where one must shout within an inch or two of the ear to make oneself heard should be noted in a survey of potentially injurious conditions. The physician, upon finding such conditions, should recommend that a study be made of the noisy environment to determine whether the intensities at existing frequencies are excessive and, if so, to determine whether practical noise-reduction measures can be taken. He might also recommend that an audiometric examination program be instituted.

Extremes of Atmospheric Pressure.—Extremes of atmospheric pressure include the high pressures encountered in foundation and tunnel construction, and in diving operations, and the low pressures of flying at high altitudes. Foundation and tunneling operations under pressure tend to be among the more hazardous.

It is likely that a full-time or part-time physician will be connected with such construction operations. Other physicians in the area may be called upon because of some temporary unavailability of the physician normally responsible, or in event of an accident causing a number of serious injuries. Also their patients may be engaged in such work. Accordingly it is desirable for physicians in the area to visit the project, become informed on compression and decompression schedules, and become familiar with the physical examinations given new workers and with instructions to workers such as checking with the physician before going under pressure in case of a coryza or ear block. Particularly where high pressures are used, the physician should become completely informed on operating conditions before he decides to enter a pressurized area. It would appear prudent for only the younger physician to do so.

In aviation medicine, it is now generally accepted that physicians should be familiar with the effects of low pressures and of too rapid subjection of the body to pressure changes.

Low pressures from high-altitude construction or mining operations are not ordinarily within the purview of most physicians. It is assumed that physicians at operations in such locations will be informed about the physiological aspects of working and living under low pressures—also about the decrease in maximum acceptable concentrations of gases, dusts, and toxic materials, as larger volume of the thinner air must be respired.

Extremes of Temperature: Heat.—In many plants the problems of heat in summertime are no different from those in nonindustrial environments generally. Since the evaporation of perspiration causes cooling of the skin, usually the better the air movement, the greater the comfort. Although high humidity in itself creates no harmful effects, it does limit the rate of evaporative cooling of the skin and can be expected to intensify the effects of high temperatures.

Many plants have local "hot spots," such as ovens, heat-treat baths, and furnaces, that cause excessive exposure to radiant heat as contrasted with heat carried by convection, or hot air. In the steel, glass, foundry, and other industries where processing is built around large-scale melting operations, control of radiant heat is a major problem.

A given amount of heat transferred to a man will have the same effect regardless of the means by which it reaches him—convection, conduction, or radiation. But the control of radiant heat is totally different from the control of the others. If a man is subjected to radiant heat, air movement over the man will not reduce his heat load. Shielding with some reflective material such as aluminum may be required.

The physician should become acquainted with the high-temperature occupations in a plant. Workers with certain circulatory defects should be placed elsewhere. Since long-term physiological effects of working in heat do not seem to be serious and acclimatization is a very real factor, the physician would ordinarily refrain from recommending the alternating of workers between hot and normal-temperature operations.

An increase in the body temperature and pulse rate results from exposure to extreme heat. Since these effects are alleviated fairly promptly on removal to cooler areas, the physician should note whether such areas are available and utilized as required. If an air-conditioned rest room can be provided, recovery is considerably more rapid.[5] When the pulse rate does not decline sufficiently during a rest period in a cooler area, more effective control measures should be recommended.

In hot occupations the physician should observe whether an adequate water supply, with salt, is available for the prevention of heat cramps and exhaustion. Salt is usually taken in tablet form. Several varieties are sold, but the enteric-coated or impregnated type seems the most satisfactory. A cooled, salted water supply is sometimes used. One teaspoonful of table salt per gallon of water is adequate. Thirst is not an accurate indicator of how much water a man needs when working in extreme heat. His fluid loss will usually exceed the replacement induced by thirst. It has been said that one benefit of salt tablets is that they result in a man's drinking more water than would otherwise be the case.

Extremes of Temperature: Cold.—Exposure to extreme cold may occur in meat-packing plants, in deep-freeze food producing and storage operations, and in flying at high altitudes. Provision of proper clothing is the principal factor to be noted. It has been stated[6] that acclimatization to cold has not been satisfactorily demonstrated. An investigation[7] of a group of 66 workers engaged many years in preserved-meat manufacture in cold rooms maintained at 0 to 2C showed a high incidence of chronic muscle and joint pains, and of upper respiratory tract involvement. Inquiry should be made of these possible manifestations of the effects of cold by the physician concerned with such exposure.

Ionizing Radiations.—Ionizing radiations are finding increasing applications in industry. Inquiry should always be made as to whether radioisotopes or x-ray units are being used or whether it is contemplated they will be introduced. Some years ago industrial radiology was limited principally to the use of radium or x-ray for making radiographs of welds and metal castings for detection of flaws. Today a considerable number of radioisotopes are employed for a variety of purposes. Cobalt-60, a powerful gamma emitter, may be used instead of radium for radiography or it may be the source of gamma radiation in recording devices for liquid levels, or in a pipe-thickness gauge. Beta emitters such as phosphorus-32 may be found in thickness gauges for application of rubber coating or in milling of aluminum foil. Even alpha emitters have an industrial use where polonium-coated bars remove static electricity from printing press rolls and other machinery where static interferes with production or safe operation. Radium also continues to be used for this latter application. The risk of inhalation or ingestion of radioactive materials, particularly alpha emitters, should be checked. Radioactive sources and devices utilizing ionizing radiations can be used with safety where adequate precautions are observed.

The physician need not be an expert in the intricacies of ionizing radiation, but he should inquire into the schedule of monitoring exposure to radiation, and review the records of radiation levels within occupied areas and of personal monitoring devices. If exposure should exceed accepted values, he should call to the attention of management the seriousness of the injury that in time may develop. Factors involved in the proper handling of radioisotopes are outlined in a paper on surveying industrial plants for safe use of these materials.[8]

Illumination.—In making a survey of any occupational environment, the adequacy of illumination should be observed. This would include intensity for a given operation and area, together with quality of illumination. This latter factor includes contrast, lack of glare, and proper brightness ratios, in respect to both artificial and daylight illumination. It is not contemplated that a detailed illumination survey will be undertaken by the physician. If his general observation indicates that the illumination is inadequate, the plant management should be referred to publications on industrial illumination[9] and advised to have an illumination survey made. In connection with the relationship of illumination to the visual demands of tasks, attention should also be directed to an adequate eye-examination program, and to suitable eye-protection equipment as well.

Harmful Operations

Repeated Motion.—Injury may be caused by repetitious movements. Attention should be given to operations that may lead to bursitis and synovitis. Information may be obtained from the plant nurse as to whether such conditions have occurred and, if so, at which operations. The physician may be able to make pertinent suggestions for adapting the operation to the physiological and anatomic limitations of the human body.

Vibration.—Compressed-air-driven hand tools are widely used in industry. In many plants the intermittency of the operation or other factos have prevented difficulty. If there has been some incidence of "white fingers" or if these tools are used routinely, reference may well be made to a paper by Dart[10] that covers this condition from the viewpoint of a practicing industrial physician. Heavy pneumatic tools such as jack-hammers reportedly may cause injury to elbow joints, but in this country cases have been few.

ACCIDENT HAZARDS

Operations and Conditions.—If the survey is made in company with the safety engineer, more attention may be given to accident hazards. A check list of operations and conditions to be noted is given by Blake.[11] Unsafe acts of workers account for a greater number of injuries than do environmental conditions and machines, but both factors are involved in the majority of accidents. Information on accident hazards and their control can be gained by a review of the accident experience of the plant and through the plant survey, and also by attending plant safety committee meetings.

SANITATION

General.—The American Standard on Sanitation[12] serves as a guide to general sanitation facilities. The physician should obtain information as to the state and local code requirements. Adequate maintenance and proper use of these facilities should be emphasized. Where difficult-to-remove materials get on the skin, the physician should learn what is provided for skin cleansing and in addition should observe what is actually used. Many a case of dermatitis is caused by use of solvents and harsh abrasive cleaners, even in plants where proper washing facilities and cleaning agents are provided.

Food Handling.—Whether food handling is directly under the plant management or is the function of a catering service, the physician should observe the methods utilized. If foodstuffs are prepared outside the plant premises, the survey should extend to such locations. Methods of refrigeration and of keeping hot foods above the temperature of bacterial germination should be noted. One should inquire into use of foodstuffs after they have been standing in serving areas during mealtime. Garbage disposal should be checked. The storage and use of pesticides in and around food handling and storage areas should be inquired into carefully.

Not only is sanitation of importance in in-plant food handling areas, but also the nutritional adequacy of foods served by the cafeteria and selected by the employees should be checked. It is difficult to change eating habits, but, where food served appears to be nutritionally inadequate, this should be investigated and then proper recommendations made to management. A threefold approach might be suggested through offering balanced meals; making them attractive; and educating personnel in food selection, particularly those greatly underweight or overweight, as well as the diabetics and others who have to watch their diet carefully.

Hazard Evaluation

The general survey of a plant will disclose some operations where hazardous materials are used under obviously safe conditions. Other operations may as obviously be hazardous and call for a recommendation to management that control measures be instituted.

In many instances potentially hazardous operations may be in progress that may or may not cause injury, depending upon the severity of the exposure. Control measures may be costly and management may be reluctant to incur such expense just to "be on the safe side," especially where competitors may not be adding the expense of such control to the cost of their product. In such a case, the question of whether a hazard actually exists may best be answered by recommending that the plant avail itself of expert professional survey services, which may include tests for atmospheric contaminants or of such biological materials as blood or urine, and recommendations for methods of hazard control based on their experience and technical findings.

Such services are available through official departments of industrial hygiene or occupational health in most of the highly industrialized states and in certain of the larger cities and counties. Private sources of these services are available and include a number of the larger casualty insurance companies, full-time consultants, and various professional and research organizations in the field of industrial health, including a number at universities.

RECORDS OF CONDITIONS IN OCCUPATIONAL ENVIRONMENT

After the survey of the industrial environment, the physician should report to management his observations and recommendations. It would also be helpful to the physician to prepare his own record for his use concerning job requirements and health hazards in the plant.

This record should include the potentially injurious materials used or otherwise present; something of the intermittency or duration of exposure to them; and whether the exposure was normally under good control, obviously requiring control, or in need of technical study for its evaluation. The operations involving the potentially hazardous materials or conditions should be listed. A graphic means of associating hazardous materials and conditions with operations or departments consists of a chart on cross-section paper with the materials and conditions along the ordinate, operations or departments along the absicissa, and notations at the intersections indicating existence of the hazard at a given operation or department.

Control Methods

The survey of the plant should include a consideration of control measures, both medical and engineering, which are or should be followed in maintenance of a healthy work force and healthful working environment. It is not proposed that the physician include engineering control as part of his activities. However, an understanding of the engineering factors involved in the control of health hazards will enhance his appreciation of the over-all health aspects of plant operation. The more common control methods are as follows.

MEDICAL CONTROL

Preplacement Examination.—The physician should ascertain the scope of the preplacement examination of all applicants for work and of special examinations of employees who are to be placed in an occupation involving exposure to some hazardous material. For example, employees to be placed in occupations involving exposure to pneumoconiosis-producing dust should be given a chest x-ray and those to be exposed to toxic substances should be given the same clinical tests that will later be used in periodic examinations, to provide base-line values.

Periodic Examination.—The physician should also ascertion which special procedures are included in periodic examinations of employees in hazardous occupations and the interpretations of the findings. If the findings point to possible health impairment, inquiry should be made as to what conditions in the plant are to blame. The intervals at which these special procedures are conducted should be determined by the severity of the hazard and modified as the hazard is brought under control. The interval between chest x-rays should be related to the period required for the development of dectectable changes.

Where a medical control program has been set up by one physician, it is advisable that another making a survey of the plant discuss his observations with that physician.

ENGINEERING CONTROL

Purpose.—The physician making a plant survey has a proper interest in engineering control measures for a number of reasons. The decision of the physician in recommending the placement of a worker at a given operation or retaining him at his accustomed occupation may depend upon the engineering control measures. The physician may have completed an initial x-ray survey of a foundry group and among the core finishers noted one man with arrested tuberculosis. As foundry work is considered by many a physician to be a laborious, hot, dusty occupation, the first thought on reading the x-ray may be that this man may better be placed in some other industry. Consultation with the safety engineer or industrial hygienist or personal survey of this employee's workplace may disclose that his job is conducted while he is at a bench equipped with well-designed local exhaust ventilation, obviously resulting in no appreciable exposure to dust. On the other hand, if an employee subject to asthma is exposed to an organic dust to which he is allergic, and the only feasible control measure is a filter-type respirator (adequate protection for the man's fellow workers), the physician might well recommend that this man be placed in a more suitable location in the plant.

The interest of the physician in engineering control serves as a stimulus to the production and maintenance departments for provision of adequate control measures. The production superintendent is occupied with getting out the product; plant maintenance departments have a backlog of work that a foreman or superintendent is pushing to get done. Provision for control of health hazards is often deferred to the next day, and the next. The physician, in observing the state of control measures, might note that the elbow in an exhaust pipe was eroded and leaking, and find an explanation for the recurrent nosebleed of the chrome plater. When the physician emphasizes need for repairing the ventilating system through the proper channels, it is probable that action will be taken promptly.

Types of Control Methods.—A number of categories of engineering control measures may be applied to reducing to safe levels exposure to hazardous materials. Where substitution of a less hazardous material is feasible, this should be done, for example, toluene for benzene as a paint diluent.

Alteration of method may serve as a control measure. This may involve a minor change such as installation of a motor-operated hoist to replace manual handling of baskets at a vapor degreaser or a major change such as replacement of beehive kilns with tunnel kilns for abrasive wheel calcining. In the latter case, the dust exposure is appreciably decreased and, in addition, efficiency of operation and quality of product are improved.

Isolation has application at many operations. One of these is the use of radioisotopes in well-shielded enclosures, with mechanical devices manipulated from the outside.

Ventilation is the most widely used method of engineering control. General ventilation refers to movement of air from an entire room or building. Local exhaust ventilation is usually more effective, since it is designed to capture the contaminating dust or gas before it escapes into the general room atmosphere.

Wet methods may serve as an effective means of dust control in certain operations. This may involve merely the use of garden watering cans to sprinkle the earth floor around a foundry molding area, or the installation of a high-powered water-sand blast for removal of cores from castings in place of the dusty operation of using pneumatic chisels. Good housekeeping, in itself, is an important control measure.

Personal protective devices have a real place as control measures. Although respirators should not be used as an inexpensive substitute for a local exhaust system, they may be recommended for operations where other control methods are not feasible and where there may be a severe exposure for a brief period. They may be used also as a supplement to other control methods. The type of respiratory protective device selected is extremely important and the physician would do well to learn specifically about the applications and limitations of such devices. Where toxic dusts or gases are present, or where the atmosphere is deficient in oxygen, devices approved for the particular exposure by the U. S. Bureau of Mines and as listed in their reports [13] should be used. Personal protective devices also include goggles, hard hats, gloves, plastic sleeves, asbestos leggings, and clothing made of aluminized fabric to ward off extreme radiant heat.

Conclusions

The purpose of this discussion has been to stimulate the interest of the physician in making surveys of plants with which he may be in contact, to suggest the manner in which he should approach such a survey, and to indicate the nature of conditions that should have his attention during the survey.

The facts obtained should influence the nature of the medical examination given workers, and findings of an examination should be interpreted in the light of such information. Care should be exercised in arriving at conclusions until there has been sufficient examination of all the facts. The mere presence of a toxic agent does not necessarily mean that the exposure is excessive or that injury will occur.

Examples of potentially hazardous materials and conditions, and the operations with which they are associated, have been included, but it is urged that the physician consult reference sources for more complete details. This will place him in better position to appreciate what he sees during the survey and help him in constructive discussion with management.

MEDICINE AT WORK

MEDICINE HELPS SOW A SEED

How could it happen in mid-20th-century America? Yet there it was in the Tennessee agricultural and mining town of 4,000: Over half the people were throwing their garbage out of doors and windows; 9 out of 10 toilets were outhouses; only 6% of the children had teeth in good condition; hundreds of the frame homes were unpainted, poorly heated, and dimly lit.

Some 2,000 miles northwestward, scores of seasonal farm laborers were suffering from malnutrition, although family incomes were as much as $150 to $350 a week from work in the beet fields and fruit orchards of Malheur County, Ore. Most of the pay was being spent in saloons and gambling joints.

Today, four years later, good health is being established in those two communities. Medicine was at work as the changes took place, but other people and organizations also were on the job. Their combined success there and elsewhere crowns a precept that is governing the rural health movement in America: Help the community to help itself to better health.

In that doctorless valley village near Knoxville, a survey team, set up by the Tennessee State Medical Association's house of delegates, conferred with community leaders. Soon an abandoned commissary building was converted into a physician's office, with local labor a major contribution. Equipment was donated, a state public health nurse arrived (part of her salary paid by women's clubs), and a labor union financed medical specialty services.

Meanwhile, in that Oregon community, state health department mobile units went to the migrant farm labor camps with Spanish-speaking nurses. This helped ease away fears and suspicions of the predominantly Mexican-American workers, many of whom had never seen a doctor in their lives. When examinations showed that some needed medical care, nearly every one paid for treatment by physicians in town. School and church authorities offered help with special courses and recreation programs. Many permanent residents personally welcomed the transients. Prizes were given weekly for the cleanest home and cleanest yard. More money is spent now on food, clothing, and medical care. And there is less business in the taverns and at the gambling tables.

Erasing the Skepticism

In those two communities, as elsewhere in rural America, one of the chief factors obstructing healthful living often has been local skepticism of medical progress in general, and of physicians in particular. Perhaps it has been a mistrust based on lack of knowledge of scientific advancements, or lack of contact with nonfarm folk who just do not "talk" the country language.

Just such hindrances to rural health worried Mrs. Charles W. Sewell of Otterbein, Ind., 11 years ago while she was administrative director of the Associated Women of the American Farm Bureau Federation. She feared the situation might be a setup for widespread quackery and for socialized medicine, and so she asked the advice of her family physician in nearby Lafayette, Dr. F. S. "Davy" Crockett (actually a distant cousin of the popularized Western hero). Dr. Crockett for some years also had been concerned about the effect of the postwar shortage of doctors in some rural areas.

Right there in his Indiana home, Dr. Crockett and Mrs. Sewell founded the American Medical Association's rural health program. Today, he heads the A. M. A. Council on Rural Health (and is also A. M. A. Vice-President), and she is on the Council's 10-member lay advisory committee. The advisors include representatives of farm and ranch organizations, rural publications, and agricultural extension services of land grant colleges.

The idea spread, until now there are rural health committees (many with their own lay advisory boards) in 46 state medical associations and scores more at the county medical society level. These cooperative efforts encompass well over 5 million people active in farm organizations and allied rural endeavors. They include the Grange with 1 million members, the American Farm Bureau Federation with 1,600,000 families, and the 4-H Clubs with over 2 million members. These millions are becoming as keenly interested in their special health problems as are the millions in Los Angeles who are concerned with air pollution and the millions in New York and Chicago who are faced with industrial accident hazards and with a high epidemic potential from crowded living conditions.

Health interest in America's hinterland has reached the point where the Iowa University School of Medicine in a few months will open the nation's first department of agricultural medicine. It will be devoted exclusively to problems in health peculiar to farming and the farm home, such as animal diseases affecting man, rural-type accidents, and the effects of pesticides and insecticides. Already, that school is working with the Washington County Medical Association, the state vocational rehabilitation office, and the Iowa and American Heart Associations in an effort to adjust farm folks to heart disease. There are similar programs for rural dwellers with cardiac conditions in Texas and Indiana.

Extension Service Helps Reduce

Not long ago in Maine, a rural county medical society set up a program to advise overweight persons how to reduce. What made the project attractive was that the university extension service joined in to show how to alter clothing to fit a slimmer figure. Now the weight-reduction program is being extended throughout the state. It is just one example of how an extension service often is the farmer's only link to medicine. Through such an agency, rural communities have made their first pleas for help in organizing clinics and asking health advice.

Mrs Charles W. Sewell of Otterbein, Ind , sought the advice of her family physician, Dr. F. S Crockett of Lafayette, in 1945 when she feared for the health of farming communities Together they founded the A M A.'s rural health program, and today they are leaders in it

Such thirst for counsel points to preventive medicine as more essential in rural areas than in any other kind of community. With sanitation and water supply often a matter of individual supervision, with remoteness of medical facilities sometimes placing a premium on personal protection against illness, the rural family poses a preventive health problem all its own.

Mental health in Cedar City, Utah, is now getting the preventive treatment before it becomes a big problem in that farm community. The county chapter of a mental health organization worked with the Utah State Medical Association and with the school board to show films and distribute pamphlets on the subject, and to encourage hiring of a psychiatric social worker for students. All this is helping certain farm people before they need the help of a psychiatrist, according to Dr. R. W. Farnsworth, a local general practitioner who helped organize the program.

Unfortunately, there was no such project in Sutherlin, Ore., last year when a local pastor told a conference of the A. M. A. Council on Rural Health: "We do not have any psychiatrists, and I know of one case where a 10-year-old boy who functions as a two-year-old is receiving treatments from a chiropractic physician." It is at Council conferences of this sort (the next is scheduled for March 7, 8, and 9 in Louisville, Ky.) that hundreds of physicians meet with hundreds of rural area representatives to relate their problems—and their successes at cooperation.

Doctors as a Community Force

Merely spending time with nonmedical groups in farm communities is shown to be a responsibility in the rural health movement. More often than not, it can be a heartening responsibility, according to Dr. B. L. Masters of Fremont, Mich. Two years ago he visited the office of his county ministers' association to ask advice on his plan to introduce sex education in the farm community's public schools. "To this day," he told an A. M. A.-sponsored study conference at Purdue University last October, "those clergymen still talk in awed tones about the fact that a doctor came to *them* for advice."

Dr. Wyatt Norvell of New Castle, Ky., tells about a colleague's wife who attended a rural PTA meeting where members were ready to decide to ask the local public health department to give Salk vaccine to all children in the community. The physician's wife suggested it was a job for private practitioners instead. So she wound up as the project's committee chairman—and helped coordinate just such a change in plans, in which the serum was given also to those unable to pay.

Just as the American farmer has evolved from a plowman to a combination business manager, meteorologist, mechanic, agronomist, accountant, and veterinarian, so has the "country doctor" of a quarter-century ago grown to the stature of expert general practitioner in many phases of medicine. Scientific advances in agriculture have been just as extensive and rapid as in medicine. Physicians are sharing some of the farmer's problems—helping him in matters of sanitation, nutrition, safety, and the new devices and chemicals on the rural scene. Meanwhile, the farm organizations are helping in health—sponsoring blood banks, safety drives, hospitalization plans, and chest x-ray drives.

Rapport, after 11 years, is now reaching such encouraging proportions that barriers of impersonality are falling left and right. At one recent Midwest meeting of physicians and farmers, the audience grinned in amused agreement, and then grinned at one another, as the speaker commented: "We have a lot in common —rugged independence, high overhead, and freedom from the 40-hour week."

ATOMIC WAR AND PEACE

Atom-splitting appeared to most people, until 1945, an unrealistic activity to occupy the imagination of professors addicted to the use of quaternions, tensor calculus, and non-Euclidean geometry. However, its overwhelming possibilities were impressed on every literate person in that year by the losses of human life at Hiroshima and Nagasaki. Developments since then have made it clear to all that atomic energy could wipe out the human race unless ways were found to control it. Atomic scientists in particular expressed their consternation at the gruesome consequences of their wartime researches, and many resolved that every effort must be made thereafter to develop peacetime uses of atomic energy. A question that must have remained unuttered in some minds was whether applications of atomic energy to the problems of the physician and the engineer might eventually save enough lives to equal the 160,000 to 480,000 lost in 1945.

Since that time, an incredible amount of constructive work has been done by scientists applying the new knowledge of artificial radioactivity in every field of research. Some conception of the magnitude of their output can be gained by perusing a few issues of the biweekly *Nuclear Science Abstracts*. A considerable fraction of this output relates to biology and medicine. But the question whether these constructive endeavors are keeping pace with military developments is still discussed. In 1955 Japanese investigators claimed that the United States had 2,500 to 3,000 atomic bombs and 25 to 30 hydrogen bombs, as compared with 300 to 500 atomic bombs and 10 to 15 hydrogen bombs in Russia. Has this impressive accomplishment in the military sphere been equaled by the accomplishments of industrial engineers, biologists, and physicians?

Encouraging thoughts on this point are suggested by the appearance of an extraordinary series of 16 volumes representing the proceedings of the International Congress in Geneva, August, 1955, entitled "Peaceful Uses of Atomic Energy." This series contains important contributions from the great laboratories of both hemispheres. Several volumes deal with the legal, administrative, physical, and geological aspects of atomic energy; several deal with the world's requirements for energy, the construction of power reactors, and many technical aspects of reactor engineering. Two volumes deal with applications in research, industry, agriculture, physiology, and biochemistry. Volumes 10 and 11 were reviewed in THE JOURNAL, November 24, page 1266; they are entitled, respectively, "Radioactive Isotopes and Nuclear Radiations in Medicine" and "Biological Effects of Radiation."

These books contain papers from India and Portugal, Argentina and Norway, Romania and Brazil, and many other countries. A contributor from Japan notes that his country now receives radioisotopes from Canada, the United Kingdom, and Holland as well as from the United States. Two North American authors describe an "accidental critical assembly excursion"—an unintended burst of gamma and neutron radiation from a water-moderated reactor—that endangered four workers; this account is paralleled by a report on two workers injured in a mishap with an experimental reactor in Russia. Perhaps equally significant is the fact that the country from which a given contribution came cannot always be guessed from the name of the author: Marcovich turns out to be from France, Parhon from Romania, Bora from India, Shapiro from Norway, Frank from Russia, Cohen from the Netherlands, Marinelli from the United States, Suppinger from Switzerland, and Brull from Belgium. The fields of research show no signs of division by nationalistic lines, and research that stands out by reason of abstruseness or ingenuity or dramatic interest is as likely to come from one country as from another. As a feat of book-making in the technical sense, these volumes also constitute a most heartening example of international cooperation. The work of innumerable secretaries, linguists, editors, typesetters, proofreaders, and others has succeeded in erasing all traces of the limitations and peculiarities of expression that might have been expected in contributions from so many countries in so many languages. It is evident that efforts to save human lives unite humanity and that medical research especially brings people together in combat against a common enemy.

These books do not yet afford a proof, to be sure, that nuclear energy in 11 years of application since 1945 has saved as many lives as were sacrificed in the two fateful days, August 6 and 9, of that year. But they certainly suggest that a tally should become possible and that a day when the total of lives saved becomes equal to the total of lives already lost will arrive. When that epoch is passed, modern man will have demonstrated his ability to handle the two-edged weapons that were placed in his hands by the discoverers of x-rays, radium, and artificial radioactivity.

ORGANIZATION SECTION

CONGRESS ON MEDICAL EDUCATION, FEB. 10-12

At the annual Congress on Medical Education and Licensure to be held at the Palmer House, Chicago, Feb. 10-12, the program will center around the problems of graduate medical education for general practice.

Last year's co-sponsored program with the Advisory Board for Medical Specialties was so successful that it was decided to have another such program during the 1957 Congress. This program will be conducted as a symposium. In addition, papers on the subject will be read, followed by short statements by representatives from the various specialty areas as to "What Should Constitute Graduate Medical Education for General Practice Today." Also, there will be a question-and-answer period.

On Monday, Feb. 11, the program will be devoted to undergraduate medical education. At that time, Dr. Herman L. Weiskotten, who is retiring at the end of the year as Chairman of the Council, will deliver his final address. Outstanding leaders will also present various approaches in an effort to answer: "Why are thoughtful medical educators so restless and dissatisfied today?" The Monday afternoon session will be on problems of postgraduate medical education. On Monday evening the Federation of State Medical Boards will hold the annual banquet, and on Tuesday, Feb. 12, the program will be devoted to the Federation of State Medical Boards. Its program is centered on "Reevaluation of the Licensing Examination."

EXHIBITS BY YOUNG SCIENTISTS AT NEW YORK MEETING

The two high school students winning top American Medical Association awards at the National Science Fair next spring will be invited to be guest exhibitors at the A.M.A.'s Annual Meeting June 3-7 in New York City. Dr. Alphonse McMahon, Chairman of the Council on Scientific Assembly, will serve as chairman of the A.M.A. judging committee at the fair. The A.M.A. awards, two first and two honorable mentions, are presented for the best exhibits in the basic medical sciences as an encouragement to scientifically talented students to enter the study of medicine.

About 800 persons will attend the National Science Fair in Los Angeles, May 9-11, featuring an expected 340 student exhibitors. More than 250,000 high school students now are building exhibits for the 1957 preliminary fairs sponsored by community groups interested in the development of young scientists.

The National Science Fair has increased in size from 13 supporting regional fairs in 1950 to the 170 fairs expected to send finalists this spring. A considerable part of this growth is due to stepped-up activity by medical societies in sponsoring or aiding local fairs. The A.M.A. House of Delegates noted this expanding participation and urged even greater support of science fairs by medical societies in a resolution adopted at the 1956 Annual Meeting. Information concerning the organization of a local high school science fair is available from Science Clubs of America, 1719 N Street, N.W., Washington, D. C.

TOWNSPEOPLE HONOR PRESIDENT-ELECT ALLMAN

Hundreds of townspeople turned out recently to honor Dr. David B. Allman of Atlantic City, N. J., who will take over the presidency of the American Medical Association at the New York session next June. Dr. Louis A. M. Krause, Baltimore, archaeologist, the principal speaker and a close friend of Dr. Allman, selected "Religion and Medicine" as the theme of his address. He paid tribute to President-Elect Allman, saying that "The title of another honor adds nothing to the worth of one who already is himself an honor to all his titles." Among many congratulatory telegrams received that evening was one from President Eisenhower, which read in part: "I congratulate you on your achievements as a physician and on your election to the highest office of the American Medical Association. This is a great responsibility and honor. I extend to you my best wishes for a successful administration."

FILM ON DEAFNESS ADDED TO A. M. A. LIBRARY

A story depicting the problems and education of a deaf child is portrayed in a 16-mm. sound film, which may be obtained from the Film Library of the American Medical Association. Entitled "Susan's Wonderful Adventure," this 29½ minute color film was produced for the Clarke School for the Deaf in Northampton, Mass., to help create a better understanding between deaf persons and those with normal hearing. The story covers about 14 years in a deaf child's life.

SURVEY OF HILL-BURTON PROGRAM

A study of the Hill-Burton Hospital Construction Program now being made by the Council on Medical Service of the American Medical Association will cover the first 10 years of the program's operation. It has been undertaken to determine to what extent the original objectives are being fulfilled, what effect recent progress in medical and hospital care may have had on these objectives, and what changes, if any, might be suggested to improve the program. Recent amendments to the Hill-Burton program include provisions for diagnostic and treatment centers. State medical associations have been asked through a brief questionnaire to report observations to the Council. Individual physicians, also, may have suggestions to offer. If so, such information should be sent directly to the Council's Committee on Medical and Related Facilities.

MEETING OF THE COUNCIL ON SCIENTIFIC ASSEMBLY, OCT. 21

The Council on Scientific Assembly met on Oct. 21, 1956, to arrange the program for the New York Meeting. Among other matters the following actions were taken:

It was voted to cooperate with the Council on Foods and Nutrition in arranging for the presentation of the Goldberger award and the Goldberger lecture at each Annual Meeting.

It was voted to cooperate with the Department of Public Relations in the selection of award winners at the National Science Fair and in the presentation of the first two award winners in the Scientific Exhibit at the New York Meeting.

A Session on Allergy to be held at the New York Meeting under the Section on Miscellaneous Topics was arranged, with Dr. Clarence Bernstein, Orlando, Fla., as Secretary.

A meeting of the Association for Research in Ophthalmology with the Section on Ophthalmology at the New York Meeting was authorized.

A request was made to the Board of Trustees for a committee to evaluate the efficacy of the various parts of the Scientific Program in regard to graduate medical education.

The Council offered its services to the Board of Trustees in studying the facilities of various cities for annual and clinical meetings.

The method of making awards in the Scientific Exhibit was discussed at length, with several recommendations for future consideration.

The Council met with the Section Secretaries and the Section Representatives to the Scientific Exhibit on Oct. 22. It was voted that:

General registration at the New York Coliseum will begin Sunday, June 2.

General scientific lectures will be given Monday morning and afternoon and Tuesday morning.

Section meetings will start Tuesday afternoon, June 4, and continue to Friday noon, June 7.

Arrangements in the New York Coliseum will accommodate the Scientific Exhibit, color television, and meeting rooms for eight sections. The other 13 sections will meet in nearby hotels.

Special features in the Scientific Exhibit include a group of exhibits on perinatal mortality with a question-and-answer conference arranged by the Section on Obstetrics and Gynecology and the Section on Pediatrics, an exhibit on pulmonary function testing with a question-and-answer conference arranged by the Section on Diseases of the Chest, an exhibit on fresh tissue pathology under the auspices of the Section on Pathology and Physiology, and physical examinations of physicians by the Section on General Practice. In addition, there will be the usual Fracture Exhibit and a Special Exhibit on Nutrition with a question-and-answer conference.

The New York Coliseum will be closed to guests of the Association on the mornings of Tuesday, Wednesday, and Thursday, June 4, 5, and 6. On these mornings, physicians only will be admitted to the Technical Exposition, the Scientific Exhibits, color television, and the meetings of the four Sections, which are being held in the Coliseum at that time.

COUNCIL ON MEDICAL SERVICE

A STUDY OF MATERNAL MORTALITY COMMITTEES

This is part 5 of a series of articles by the Committee on Maternal and Child Care of the Council on Medical Service reviewing the organization and operation of maternal mortality study committees. The purpose of this specific study is to obtain information that may be utilized in the preparation of guides that in turn may be helpful in the development and operation of maternal mortality committees in other areas of the United States. The descriptive material to follow is concerned with the Maternal Health Committee of the Michigan State Medical Society. (Part 6 will describe the activities of the Maternal Welfare Committee of the Wayne County Medical Society; this study is an integral part of the statewide program but is modified in some respects in order to better meet the local needs.)

Michigan Maternal Health Committee Study

History.—The study of maternal deaths in Michigan dates back to the early years when the Bureau of Maternal and Child Health of the Michigan Department of Health was established. The first study, covering the period July, 1926, to January, 1929, was made, with the approval of the Michigan State Medical Society, under supervision of the director of that bureau. At the same time, a similar study was conducted in Detroit. Since no report was published, the study received little recognition.

In 1933, the Maternal Welfare Committee of the Michigan State Medical Society was organized under the leadership of physicians dedicated to improving maternal health services and reducing maternal deaths. Up to the time of the inauguration of the present statewide program in 1950, this committee conducted numerous surveys and educational programs and promoted refresher courses in obstetrics throughout the state. During the same period, local studies of maternal deaths were conducted for various lengths of time in Detroit, Grand Rapids, Pontiac, and Flint. This state medical society committee became known, in 1949, as the Maternal Health Committee, and, in 1950, in cooperation with the Michigan Department of Health, it began the statewide study of maternal deaths. Now in its seventh year, the study is definitely accepted as a proper joint function of the medical society and the health department. The purpose of the study is primarily educational; it is directed by and for physicians in their efforts to improve maternal care. The objective, of course, is the reduction of maternal mortality and morbidity in the state.

Members.—All areas of the state were represented on the Maternal Health Committee, and appointments are made by the president of the state medical society on the recommendation of the chairman. The director and the obstetric consultant of the Maternal and Child Health Division of the Michigan Department of Health are members. Other members of the committee include an anesthesiologist, a pathologist, a cardiologist, and five general practitioners. The remaining members—approximately 20—are obstetricians. Many of the members have been reappointed each year: thus there are some who have been on the committee for over 15 years. Within the Maternal Health Committee are subcommittees on study, evaluation, and publications. In addition, a group of 18 regional consulting obstetricians, all of whom are board certified and several of whom are committee members, are officially designated as collectors of study data.

Scope of Study.—Deaths of women who are known to be pregnant or deaths occurring not more than 90 days post partum are defined as maternal deaths and are included in the study. The committee is not concerned with nonmaternal deaths, and, therefore, this term is not used in the committee's study. The maternal deaths are classified as due to either obstetric or nonobstetric causes. The maternal mortality rate includes only those maternal deaths classified as due to obstetric causes.

Classification as to obstetric or nonobstetric cause of maternal death is based upon whether the cause of death was directly related to the pregnancy or its obstetric management. Deaths from hemorrhage, for instance, are categorically classified as due to obstetric causes, whereas most cases of heart disease are categorically classified as due to nonobstetric causes. If, however, obstetric management of a patient with heart disease was at fault, the death is classified as obstetric. Deaths due to anesthesia during delivery are classified as obstetric, because, if the patient had not been pregnant, she would not have been given the anesthesia; such deaths, therefore, belong in the category of those due to obstetric management. Deaths from infections, such as poliomyelitis and tuberculosis, are classified as nonobstetric, whereas deaths in certain cases of pneumonia and most septicemias and infections due to abortion are classified as due to obstetric causes. In the broad classification of toxemia, only those cases of death from essential hypertension with superimposed preeclampsia or eclampsia are classified as obstetric, while those deaths from essential hypertension per se and diseases of the genitourinary tract, such as acute nephritis, chronic nephritis, and pyelonephritis (unless obstetrically mismanaged), are classified as nonobstetric. There are other less common causes of maternal deaths. Sometimes, in the puerperium, there is sudden death from an unknown cause; sometimes there are incompatible transfusion reactions. Such deaths are classified as obstetric. Less common nonobstetric causes of maternal deaths include various types of malignancies, cerebral vascular accidents, diabetes, accidental deaths, and such isolated causes as idiopathic or thrombopenic purpura and leukemia.

Operation: Agencies and Personnel Involved.—The first step in the operation of the Michigan maternal mortality study program is the direct reporting of maternal deaths to the Maternal and Child Health Division of the Michigan Department of Health by the physicians, hospitals, and local health departments of the state. In addition, the Division of Records and Statistics of the health department, which receives all official death certificates, transmits photostatic copies of those coded as maternal deaths and those on which mention of pregnancy or complication of pregnancy is made to the Maternal and Child Health Division. On receipt of these reports, the division office furnishes identifying information to the appropriate regional consulting obstetricians. The consultants then make arrangements for a complete study of each death.

A method of combined questionnaire-personal visit is used in carrying on the study. The consultant discusses the case with the attending physician, reviews the physician's and the hospital's records, and interviews consultants in the case and hospital personnel. If complete data are not available through these sources, he will make arrangements, through the attending physician, for interviewing relatives of the patient or others.

All pertinent data are recorded on the questionnaire form of the Michigan maternal mortality study. To this is added the case summary obtained from the attending physician as well as the regional consulting obstetrician's summary of the data that he has collected. The latter includes notes on the type of hospital facilities, their adequacy, and the adequacy of the medical records and observations on hospital personnel and their competence. The questionnaire and other summaries and comments are sent back to the office of the Maternal and Child Health Division. There all identifying data are removed, and the coded reports are then ready for distribution to the members of the evaluation subcommittee.

The evaluation subcommittee meets at necessary intervals, reviews each case, and determines whether the death was due to obstetric or nonobstetric causes and whether it was preventable. If the death is classified as preventable, responsibility is assigned to the patient, the physician, the consultant, the hospital, or to any combination of these. The publications subcommittee, in cooperation with the Maternal and Child Health Division and the Statistical Methods Section of the Department of Health, makes the final classifications and prepares the material for presentation to the council of the state medical society for approval prior to publication in the state or other medical journals. In counties, such as Wayne and Oakland, where the local medical societies have maternal mortality study committees, the Maternal and Child Health Division routes duplicates of the completed questionnaire and other related material to that county society committee for its analysis, evaluation, and follow-up action. The original material is forwarded to the evaluation subcommittee of the Michigan State Medical Society. After all evaluations and analyses have been completed, all data are again returned to the office of the Maternal and Child Health Division, where they are safely filed. The summaries of attending physicians and regional consulting obstetricians are filed separately from the questionnaires.

Expenses incurred in these studies are shared by the department of health and the state medical society. The department of health pays the regional consulting obstetricians $25 per case, plus traveling expenses; it pays the members of the evaluation subcommittee an honorarium of $25 per session. The state medical society and committee members take care of the expenses of committee and subcommittee meetings and publication of the material.

Follow-Up.—A detailed report on the Michigan maternal mortality study for the three-year period 1950 through 1952 was published in the February, 1955, *Journal of the Michigan State Medical Society.* The issue was a special maternal health number dedicated to the memory of Dr. Alexander M. Campbell, who had done so much in Michigan toward the improvement of maternal care and services. It contained a complete history of maternal mortality studies in Michigan; the history and philosophy of the hospital consultation and licensing program as conducted by the Michigan Department of Health; and an over-all report on the Michigan maternal mortality study for the three-year period. This latter report included graphs and tables showing causes of death, obstetric and nonobstetric, in six main categories: (1) hemorrhage, (2) infection, (3) toxemia, (4) heart disease, (5) anesthesia, and (6) all other causes. In addition, detailed articles on each of these categories gave a breakdown of the factors associated with that particular main cause of death. Analyses were presented on why particular maternal deaths occurred, with suggestions as to how the cases should have been diagnosed and how more appropriate and effective treatment might have been given. A summary and conclusion followed at the end of each article, stating in brief terms what should be done henceforth to prevent many of these deaths.

TABLE 1.—*Data on Maternal Deaths Due to Obstetric and Nonobstetric Causes* from Michigan Maternal Mortality Study, 1950-1952*

Category	Obstetric Causes	Nonobstetric Causes	Total
Hemorrhage	101	.	101
Infection	43	32	75
Toxemia	63	10	73
Heart disease		28	28
Anesthesia	22	..	22
All other causes†	32	51	83
Total	261	121	382

* From Hersey and Sutton,[1] table 1 with modifications.

† Obstetric: Chorioepithelioma, 6; abortion, 5; puerperal pulmonary embolism, 5; immunization with Rh factor, 3; incompatible transfusion reaction, 2; *delivery with other trauma*, 1; and sudden death from unknown cause in the puerperium, 10. Nonobstetric: carcinoma, 9; cerebral hemorrhage, 7; diabetes mellitus, 5; motor vehicle accident, 4; glioblastoma, 2; *pulmonary* embolism, 2; mesenteric infarction, 2; poisoning, (ergot and magnesium sulfate), 2; deaths from unknown cause, 6; and others, 12

From time to time various articles have appeared in county medical society bulletins, sometimes accompanied by open letters to the medical profession. One such series of letters, signed by the chairman of the Maternal Health Committee, the state commissioner of health, and the president of the Michigan State Medical Society, stated the objectives of the Maternal Health Committee, outlined some of the most frequent causes of maternal deaths, and emphasized certain factors that were considered preventable. They also called attention to the licensing of maternity hospitals, now the responsibility of the Michigan Department of Health, and the establishment of minimum rules and standards in consultation with and with the approval of the Michigan State Medical Society.

Through this type of professional publicity, physicians practicing obstetrics and gynecology and hospital administrators throughout the state have learned of the activities of the Maternal Health Committee and that its study of maternal deaths is not disciplinary in nature but is primarily educational, designed to assist the profession in improving obstetric care. To assist in this, the Michigan Society of Obstetricians and Gynecologists devotes one meeting each year to a review of the studies made by the Maternal Health Committee of the Michigan State Medical Society and the Maternal Welfare Committee of the Wayne County Medical Society.

Another method used by the Maternal Health Committee to stimulate further action by an individual county or by groups of counties is to bring its committee meetings to various parts of the state. Undergraduate and graduate education in obstetrics is also furthered in the two university medical school centers through lectures based upon committee findings and through actual participation programs in which the students discuss special cases. This is feasible since representatives from both medical schools serve on the evaluation subcommittee. A newly formed Maternal Mortality Study Committee in one of the counties (Oakland) is tape-recording the discussion and evaluation of maternal deaths studied by them. This is a new innovation, and the value of its results remains to be seen.

The Maternal Health Committee has not received permission as yet from the Michigan State Medical Society to send follow-up letters concerning the findings of the evaluation subcommittee on maternal deaths to the particular physician and/or hospital involved. In the Wayne County maternal mortality study, however, follow-up letters of committee findings are sent directly to the attending physician, the chief of obstetrics, and the administrator of the hospital in which the maternal death occurred.

Results.—The results of the first study of maternal deaths from July 1, 1926, to Dec. 31, 1928, in the state of Michigan indicated 1,627 deaths in 245,312 live births. This is in contrast to the 271 deaths from comparable causes in 510,341 live births during the three-year period from 1950 through 1952.

Table 1 summarizes the Michigan maternal mortality study for the three-year period in two main categories, obstetric or nonobstetric causes. The footnotes to this table indicate the main causes of those maternal deaths classified as "All other causes." Table 2 gives a comparison between maternal mortality rate based upon the maternal mortality study of the Michigan Maternal Health Committee and the maternal mortality rate as recorded by the Michigan Department of Health, Division of Statistics and Records. The slight discrepancy between the two rates is accounted for by the fact that the figures of the department of health were taken directly from the death certificates, which, in some cases, the Maternal Health Committee found inaccurate as to actual cause of death. Provisional reports based on death certificates for 1955 indicate a maternal mortality rate for the state of 0.3 maternal deaths (from obstetric causes) per 1,000 live births. This reveals clearly the progress that has taken place in the reduction of maternal deaths in the state of Michigan since the inception of the statewide study in 1950. Although the committee has evaluated preventability, statistics on this aspect of their study have not been reported.

It is of interest to note that also in the three-year period 1950 through 1952 the rate of infants saved was only 38% of the number of those mothers who died from obstetric causes; the rate was only 25% of the number of those who died from nonobstetric causes. This infant survival rate is slightly less than the infant survival rate (40.8%) recorded for the 1926-to-1928 study.

Comments and Conclusions.—The Maternal Health Committee of the Michigan State Medical Society in conjunction with the Michigan Department of Health has been confident that the study of maternal deaths would lead to a greater improvement in maternal care than would be possible without such a study. The recent low of 0.3 maternal deaths per 1,000 live births in Michigan would seem to justify that confidence. It is difficult to assess the factors most responsible for these dramatic reductions. The Maternal Health Committee feels, however, that the current study, which began in 1950, has assisted materially in that reduction. The publication of critical analyses of the various causes of maternal deaths has great postgraduate educational value to the practicing physicians throughout the state, as well as to the undergraduates in the medical centers of Michigan. It has also resulted in emphasis being given to alerting the public to the fact that early prenatal care is essential in order to reduce the number of deaths.

To arouse public awareness, the state and local health departments have undertaken specific educational programs. In addition, the Michigan Department of Health, as a part of its responsibility for licensing maternity hospitals and homes, provides advice and consultation to the various hospitals and maternity units needing such service in order that they may be aided in meeting the requirements for a license to operate in Michigan. The direct responsibility for this program has rested with the Maternal and Child Health Division and has been carried out in cooperation with other divisions of the state and local health departments. If minimum standards are not met by a hospital and the hospital is needed in the community, it is given a provisional license that allows it to function as such for a period of one year. These provisional licenses can only be renewed two times, and at the end of that three-year period, if the hospital has not met or complied with all the regulations, the license will be revoked. The Michigan Department of Health has had the active participation of members of the Maternal Health Committee for advice and guidance in this licensing program.

Results, since 1951, indicate what physicians and hospitals have done to improve patient care. In 1952, 114 of the approximately 260 hospitals listed had provisional licenses. The basic philosophy of the department of health on the whole licensing program has been to provide advice and consultation to the hospitals, rather than just to point out what is wrong, so that they will better be able to meet the requirements. In this program the health department has had complete cooperation from the Maternal Health Committee of the Michigan State Medical Society; all have worked together harmoniously to assure that good facilities and services are available for mothers and infants in Michigan.

In the course of the work of the Maternal Health Committee, it has become obvious that autopsies are not performed in many of the cases of maternal death in which the cause of death may be in question. In order to solve this problem, a committee, consisting of three pathologists and three members of the Maternal Health Committee, was appointed jointly by the Maternal Health Committee and the state pathological society. This committee is charged with the responsibility of recommending ways and means by which a pathologist might be made available to any physician in the state who needs the service. It is also charged with the responsibility of exploring the establishment of a registration of maternal tissues and determining how such a registration can be accomplished and where it would be best housed.

From the reports published thus far on the activities and accomplishments of the Maternal Health Committee, and with a minimum of emphasis upon specific instances of preventability and responsibility, much progress has been made. However, the Maternal Health Committee hopes to arrive at a solution as to how a more complete analysis can be presented and made more widely known among those in the profession who are concerned with the care of maternity patients. Therefore, in order to promote greater utilization of current knowledge relative to the management of obstetric complications, the Maternal Health Committee plans to present this survey material in more detail at state meetings, at programs in county meetings, and in more frequent publications in the *Journal of the Michigan State Medical Society* and other medical journals. The committee recommends that legislation be enacted that would result in legal immunity regarding information obtained and conclusions reached in the study of maternal deaths. Such a step would go far in allaying the fears of some physicians who perhaps then would cooperate more fully and would, consequently, receive greater benefits from the study. In spite of the fact that during the years of operating an active study of maternal deaths in the state of Michigan there have been no legal complications, the Maternal Health Committee feels that more improvements will result if legislation is enacted to prevent any possible legal entanglements or fears of such entanglements.

TABLE 2.—*Maternal Mortality Rate per 1,000 Live Births**

	1950		1951		1952	
	Deaths	Rate	Deaths	Rate	Deaths	Rate
Michigan Maternal Mortality Study	84	0.52	89	0.52	88	0.51
Michigan Department of Health	91	0.57	94	0.54	82	0.46

MEDICAL NEWS

ARKANSAS

Narcotic Violation.—Dr. Spriggs B. Banks, of Forrest City, pleaded guilty in Federal Court, Helena, Sept. 10, 1956, to a violation of the federal narcotic law. On Sept. 24, he was sentenced to a term of two years in custody of the U. S. attorney general and to three-years' probation on completion of the two-year sentence.

Meeting on Surgery.—The Arkansas chapter of the American College of Surgeons and the University of Arkansas Medical Center will hold a question-and-answer panel on surgery and surgical specialties, Dec. 9, at the medical center in Little Rock. Panels will be presented on general surgery, traumatic surgery, urology, and gynecology and obstetrics. Registration fee is $5; registrants will be guests at luncheon, 12:45 p. m., in the medical center cafeteria.

CALIFORNIA

Dr. Katz to Address Cardiac Conference.—Dr. Louis N. Katz, chief, cardiovascular research, Michael Reese Hospital, Chicago, will address the Cardiac Surgical Conference of Mount Zion Hospital, San Francisco, Dec. 15, 10:15 a. m. in Herbst Hall, on "Some Dynamics of Circulation."

Personal.—Dr. Leo J. Adelstein, Los Angeles, has been appointed by Governor Knight as a member of the state board of medical examiners for the term ending Jan. 15, 1960.——Dr. Joseph F. Ross, professor of medicine, University of California School of Medicine, Los Angeles, has been appointed a member of the National Advisory Cancer Council, the surgeon general of the U. S. Public Health Service has announced.——Dr. James L. Dennis, coordinator of resident instruction, has been appointed full-time medical director of Children's Hospital of the East Bay in Oakland. Dr. Dennis formerly was assistant professor of pediatrics and assistant administrator of medical affairs at the University of Texas Medical Branch Hospitals in Galveston.——Dr. Arnold D. Schwartz has been appointed chief of the mental health services of the state department of public health, the first person to occupy this position since the resignation of Dr. Kent A. Zimmerman in May, 1954. Dr. Schwartz has been affiliated with the San Bernardino County Charity Hospital, San Bernardino.——Dr. John W. Brown has joined the state department of public health, bureau of acute communicable diseases. Formerly he was a consultant in infectious diseases for the student health services and the department of occupational health at the Ernest V. Cowell Memorial Hospital, University of California, Berkeley. He is presently a member of the committee on public health and preventive medicine of the National Board of Medical Examiners.

COLORADO

Appoint Dean of Medical School.—Dr. Robert J. Glaser, 38, associate dean of the Washington University School of Medicine, St. Louis, has been appointed dean of the University of Colorado School of Medicine, Denver, to succeed Robert C. Lewis, Ph.D., who retired as dean June 30 after 40 years of service as a member of the medical faculty. Dr. Glaser is scheduled to assume his new post about Feb. 1. He joined the faculty of Washington University School of Medicine in 1945 and currently is associate professor of medicine and associate dean.

CONNECTICUT

Groedel Medal to Dr. Fulton.—At the annual meeting in Chicago, the American College of Cardiology named as the first recipient of the Groedel medal Dr. John F. Fulton, Sterling Professor of the History of Medicine, Yale University School of Medicine, New Haven. The award, given "for outstanding contributions in physiology and history of medicine" is named in honor of the late Dr. Franz M. Groedel, founder of the American College of Cardiology. The silver medal was designed by Dr. Hannibal DeBellis, a trustee of the college.

ILLINOIS

Chicago

Grant for Cancer Research.—The Damon Runyon Memorial Fund for Cancer Research has allocated a grant of $12,000 to the Hektoen Institute for Medical Research of Cook County Hospital, for studies in leukemia under the direction of Dr. Steven O. Schwartz and his associates. This is the second yearly grant that the organization has given the institute.

Courses on Radiological and Health Physics.—The University of Chicago will offer courses in health physics and radiological physics, this winter in the department of radiology. The courses are both two-year programs leading to the master's degree Physicists, biologists, and doctors will participate in the instruction. During the second year of the courses, students will be employed half-time either in the university's Health Physics Service or in the department of radiology.

Fund to Help Disabled Physicians.—Money is presently available in the Dr. Adolph Gehrmann fund for sick or disabled physicians in need of financial assistance or for the widow of any physician for a period of not more than one year after the death of the husband. The fund cannot be used as an old age pension for physicians but must adhere to the statement in the will to help "in his or their attempt to regain health." Inquiries should be made to the Chicago Community Trust, 10 S. La Salle St, Chicago 3 (telephone—FRanklin 2-3356).

In Memory of Kellogg Speed.—At 8 p. m., Dec. 14, the Chicago Orthopaedic Society will present a program honoring the memory of Dr. Kellogg Speed, honorary member of the society and founding member of the American Board of Orthopedic Surgery, who died July 2, 1955. Dr. Arthur H. Conley will have as his topic "Dr. Speed, the Rebel." "Swivel Ball Hip Prosthesis" will be discussed by Dr. Carlo S. Scuderi, "Dislocations of the Shoulder" by Dr. James J. Callahan, and "Various Uses of the Kuntscher Nail" by Dr. Horace E. Turner. All physicians are cordially invited to attend the scientific program, which will be held in private dining room 17 of the Palmer House (telephone RAndolph 6-7500). The meeting will be preceded by dinner at 6:45 p. m.

Writers' Association Award to Dr. Fishbein.—Dr. Morris Fishbein, for many years Editor of THE JOURNAL, is the recipient of the 1956 Distinguished Service award of the American Medical Writers' Association, given annually to a member "who has made distinguished contributions to medical literature or rendered unusual and distinguished service to the medical profession." The award, comprising a plaque and gold medal, wa presented to Dr. Fishbein by the president of the association, Dr Richard M. Hewitt, Rochester, Minn., who formerly was Assistant Editor of THE JOURNAL. The presentation was made at th 13th annual meeting of the association in Chicago, Sept. 28.

Personal.—Dr. Michael H. Boley, clinical assistant professor c
obstetrics and gynecology, University of Illinois College of Medi
cine, has returned from a study and lecture tour through Austri
and Germany. He lectured in German on "Management c
Obstetric Difficulties" before the medical faculty and the sta
of the Frauenklinik of Frankfurt University on May 28 an
before the Faculty and Frauenklinik of Heidelberg Universit
on May 29. On June 7 he lectured on "The Present Status c
the Management of Cervical Carcinoma" before the Frauen
klinik and the Faculty of Medicine in Dusseldorf. Dr. Bole
conducted informal seminars at clinics in both countrie
on postgraduate medical education in obstetrics and gynecolog
in the United States.——The Schering Corporation of Bloomfield
N. J., recently awarded second prize ($250) in its internation

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting contest for medical students to Dr. Paul J. Jorden, Chicago, for his paper on trends in the clinical use of adrenocortical steroids. Dr. Jorden is interning at West Suburban Hospital in Oak Park.

KANSAS

Memorial for Dr. Sudler.—Friends of the late Dr. Mervin T. Sudler, former dean of the University of Kansas School of Medicine, Kansas City, who died on June 22, have announced plans for a memorial. Those wishing to contribute to the fund may send checks to the American Medical Education Foundation, 535 N. Dearborn St., Chicago 10. An attached letter should stipulate that the contribution is for the Sudler Memorial Fund and for the University of Kansas School of Medicine.

LOUISIANA

Fellowships in Tropical Medicine.—The Louisiana State University fellowship program to assist teachers from U. S. medical schools in obtaining practical experience in tropical medicine in the American tropics is now in its second year of operation. The program, conducted by Dr. Henry E. Meleney, research professor of medicine, and Dr. William W. Frye, dean and professor of tropical medicine, has already given 33 teachers the experience of two months in the tropics. The original grant of $80,000 from the China Medical Board of New York, which provided financial support for two years, has been augmented by a grant of $40,000 for the third year. The fellows selected spend two days at the Louisiana State University School of Medicine, New Orleans, in an orientation program before proceeding to Central America or the Caribbean islands for eight weeks.

Personal.—A golden anniversary dinner was held recently at the St. Francis Hospital in Monroe, honoring Dr. James Q. Graves of Monroe on the anniversary of his 50 years in the practice of medicine. Dr. Graves has also served 29 years as a member of the House of Delegates of the A. M. A. Dr. Rufus B. Robins, Camden, Ark., gave the address of the occasion, "Fifty Years of Service." An operating room at the St. Francis Hospital was dedicated to Dr. Graves. The meeting was attended by Congressman Otto Passman of Louisiana, Federal District Judge D. W. Dawkins, and other distinguished guests.

MASSACHUSETTS

Dr. Joslin Honored.—Dr. Elliott P. Joslin, Boston, was decorated with the cravat of the commander of the Legion of Honor by the French government at a recent Lafayette Day reception in the French consulate in Boston.

Society News.—The Massachusetts Medical Society (22 The Fenway, Boston 15,) announces that as of Jan. 1, 1957, Mr. Robert St. B. Boyd will retire as executive secretary. General correspondence will be handled through the office of the secretary of the society, Dr. Robert W. Buck.

Dr. Rock Becomes Emeritus Professor.—Dr. John Rock, Brookline, who has been associated with Harvard Medical School, Boston, since 1922, has retired from the university to become clinical professor of gynecology, emeritus. Dr. Rock, who serves currently as consulting gynecologist and director of the Rock Reproductive Study Center at the Free Hospital for Women in Brookline and as a member of the board of consultants of the Massachusetts General Hospital, established one of the first fertility clinics in this country at the Free Hospital for Women and served as its director for nearly 30 years. He is a former president of the Obstetrical Society of Boston, honorary vice-president of the American Society for the Study of Sterility, and honorary member of the Société Française de Gynecologie. He holds the Lasker award of the Planned Parenthood Federation of America and the Ortho award of the American Gynecological Society.

Dr. Wood Retires.—About 250 friends from McLean Hospital and the Massachusetts General Hospital gave an informal buffet to honor Dr. W. Franklin Wood, Belmont, who has retired as director of McLean. Before coming to McLean he had been affiliated with the Massachusetts General Hospital, Massachusetts Department of Mental Health, Boston Psychopathic Hospital, the Massachusetts Memorial Hospitals in Boston, the Monson State Hospital in Palmer, and the Danvers State Hospital. Dr. Wood has been president and secretary of the Massachusetts Hospital Association and of the New England Hospital Assembly, regent of the American College of Hospital Administrators, and president of the New England Superintendents Club. He is psychiatric consultant at the Massachusetts Department of Mental Health and at the Leslie Junior College in Cambridge and has been appointed school physician at the Belmont schools.

MISSISSIPPI

Grants to Dr. Hardy.—The department of surgery at the University of Mississippi Medical Center, Jackson, has announced the following research grants to Dr. James D. Hardy, chairman of the department: from the National Heart Institute, $34,500 yearly for five years for the development and promotion of departmental research in the cardiovascular field; from the division of research grants, National Heart Institute, $25,000 yearly for five years; from the office of the surgeon general, Department of the Army, $39,902.50, renewal for one year, to study patient reaction to anesthesia, operation, and accidental trauma; from the Mississippi Heart Association, $2,400 for one year, to study methods of prevention and treatment of myocardial infarction.

University News.—The department of surgery at the University of Mississippi Medical Center, Jackson, has added the following faculty members: Dr. William F. Enneking, associate professor of orthopedics, formerly instructor in orthopedic surgery at the University of Chicago School of Medicine; Dr. Curtis P. Artz, associate professor of surgery, formerly director of surgical research, U. S. Army Hospital, Fort Sam Houston, Texas, and clinical assistant professor of surgery at Baylor University College of Medicine, Houston; and Dr. Jorge Rodriguez, assistant professor of surgical anatomy and associate in research, formerly of St. Mary's Memorial Hospital, Knoxville, Tenn. Dr. Wanza B. Inmon, who completed his residency in obstetrics-gynecology at the center in July, has been named instructor in that department.

NEW YORK

Society News.—The annual meeting of the Medical Society of the State of New York will take place at the Hotel Statler, New York City, Feb. 18-21, 1957, in celebration of the society's sesquicentennial. The house of delegates will meet in the same location on May 13-15, 1957.

Appoint Professor of Pediatrics.—Dr. Joseph B. Pincus has been appointed full-time professor of pediatrics at the State University of New York College of Medicine at New York City, Brooklyn, and director of pediatrics at the Jewish Hospital of Brooklyn. Until recently he was clinical professor at the college and part-time chief of pediatrics at the hospital.

Appointed Acting Dean.—Wilfred W. Westerfeld, Ph.D., chairman, department of biochemistry since 1945, has been appointed acting dean of the State University of New York College of Medicine in Syracuse. Dr. Westerfeld will serve until the appointment of a dean. The present dean, Dr. William R. Willard, has resigned to become dean of the University of Kentucky Medical School at Lexington.

Society News.—At the October meeting of the Brooklyn Dermatological Society, Dr. Benjamin D. Erger was elected president, Dr. Samuel B. Frischberg, vice-president; and Dr. Morris J. Rothstein, secretary-treasurer. The society holds its meetings on the second Tuesday of each month at 8:30 p.m. from October to May, at the Brooklyn Hospital Clinic at Ashland Place and DeKalb Avenue, Brooklyn.

Community Honors Price Lewis.—Dr. Price Lewis of Holland Patent, N.Y., was recently honored on the observance of his 50th year in practice when members of the community presented him with the Dr. Price Lewis Scholarship, presently worth $3,600, that will be offered annually to a Holland Patent Central School senior who indicates his intention of becoming a physician. Dr. Lewis, health officer of the Consolidated Health District, serves also as school physician for the Holland Patent Central School.

New York City

Harvey Lecture.—The fourth Harvey Lecture in the present series, "Metabolism in Trauma: The Meaning of Definitive Surgery," will be delivered Dec. 20, 8:30 p.m., at the New York Academy of Medicine, 103rd Street and Fifth Avenue, by Dr. Francis D. Moore, Mosely Professor of Surgery, Harvard Medical School, and surgeon-in-chief, Peter Bent Brigham Hospital, Boston.

Laboratory for Experimental Surgery.—Dr. Godfrey Nurse recently donated to Harlem Hospital $100,000 for the equipment and operation of a laboratory for surgical investigation that will be a unit of the department of surgery. The laboratory will be called the Godfrey Nurse Laboratory for Experimental Surgery. Named as trustees of the endowment are Dr. Aubre De L. Maynard, present director of the department of surgery at the hospital, and Dr. Henry W. Cave, a past-president of the American College of Surgeons.

Society News.—The New York Institute of Clinical Oral Pathology announces that its monthly conference, 8:30 p.m., Dec. 17, at the New York Academy of Medicine Building, 2 E. 103rd St., will be an open meeting to which the members of the medical, dental, and allied professions are cordially invited. Albert Schatz, Ph.D., director of research and professor of microbiology, National Agricultural College, Doylestown, Pa., will lecture on "Introspections of a Soil Microbiologist on the Etiology of Dental Caries."

Alvarenga Prize to Dr. Papanicolaou.—On July 14 the College of Physicians of Philadelphia awarded the Alvarenga prize for 1956 to Dr. George N. Papanicolaou, director, Papanicolaou Research Laboratory, Cornell University Medical College, for his work in the early detection of cancer. The Alvarenga prize, established by the will of Pedro Francisco DaCosta Alvarenga of Lisbon, Portu', an associate fellow of the College of Physicians of Philadel ia, is awarded annually on the anniversary of the death of the stator, July 14, 1883.

Research in Causes of Deafness.—The Alfred P. Sloan Foundation has granted $82,000 to New York University–Bellevue Medical Center in support of a project resulting partially from findings established through a pilot study that the foundation supported at the center. The grant was made directly to the postgraduate medical school, department of otolaryngology, of which Dr. John F. Daly is professor and chairman. The director of the hearing project will be R. Joseph E. Hawkins Jr., Ph.D., Rahway, N. J., who has done extensive research on the effects of antibiotics such as streptomycin and neomycin on the inner ear.

Course in Radium Therapy.—A course in operative radium therapy will be offered at the Queens General Hospital, Jamaica, by the radiation therapy department on nine consecutive Saturdays (9 a.m.–12 noon) beginning Jan. 5, 1957. The program will include the use of interstitial radiation in the oral cavity, radical insertion of radium in the neck, radium therapy in postoperative carcinoma of the breast, use of different applicators in carcinoma of the cervix, of the Heyman applicator in carcinoma of the endometrium, of radium needles in the parametrium, and of radon, iridium-thread, and cobalt interstitial therapy. Apply to Dr. Leonard B. Goldman, Director, Department of Radiation Therapy, Queens General Hospital, 82-68 164th St., Jamaica 32.

Personal.—Dr. John A. Di Fiore has been appointed by Governor Harriman as a member of the medical appeals unit of the New York State Workmen's Compensation Board.——The Haitian government, through its consul general, has made Dr. Harry Katz an officer of the Legion of Honor.——The Public Health Research Institute of the City of New York has conferred the title of director emeritus on Dr. L. Whittington Gorham and named Dr. George K. Hirst acting director.——Dr. Samuel J. Prigal recently addressed the National Institute of Allergy and Infectious Diseases, National Institutes of Health in Bethesda, Md., on "Interrelationship of Allergy and Infection."——Dr. Alexander Brunschwig, professor of clinical surgery, Cornell University Medical College, has returned from a two-weeks' tour in Russia, where he visited surgical clinics, cancer institutes, research centers, and medical schools in Moscow and Leningrad.

State Launches Psychiatric Training Program.—A program for advanced training of psychiatrists in the New York State mental hygiene institutions was launched in September under the joint direction of the State University of New York and the New York State Department of Mental Hygiene. The program provides training for medical staffs of six mental hygiene institutions (Brooklyn, Creedmoor, Kings Park, Pilgrim, and Central Islip State hospitals and the Willowbrook State School) in the metropolitan area in cooperation with the faculty of the State University of New York College of Medicine at New York City, Brooklyn. A similar program is planned for upstate mental hospitals, centered around the state university medical school at Syracuse. Dr. Sandor Rado, recently retired from the psychiatric faculty of the Columbia University College of Physicians and Surgeons and the New York State Psychiatric Institute, is director of the metropolitan area program.

OKLAHOMA

Society News.—Dr. Milford S. Ungerman, Tulsa, has been elected president of the Oklahoma Society of Neurologists and Psychiatrists and the Oklahoma District Branch of the American Psychiatric Association; Dr. John F. Gray Jr., Tulsa, vice-president; Dr. Harold G. Sleeper, Oklahoma City, president-elect; and Dr. Charles A. Smith, Norman, secretary and treasurer.

University News.—Dr. Louis J. West has assumed his duties as full-time head of the department of psychiatry at the University of Oklahoma School of Medicine, Oklahoma City, following his release from active duty with the U. S. Air Force.——Dr. John A. Schilling has been appointed the first full-time head of the department of surgery at the University of Oklahoma School of Medicine, Oklahoma City. Dr. Schilling was assistant professor of surgery at the University of Rochester (N. Y.) School of Medicine and Dentistry before coming to Oklahoma.

SOUTH DAKOTA

Distinguished Service Awards.—At its 75th annual meeting in Aberdeen, the South Dakota State Medical Association bestowed its distinguished service award on Dr. Joseph C. Ohlmacher, dean emeritus of the University of South Dakota School of Medical Science, Vermillion.——At its annual awards banquet the Geneva College Alumni Association bestowed on Dr. Frank S. Howe, Deadwood, one of its distinguished service awards for 1956.

TENNESSEE

Gift to Seizure Clinic.—The new Children's Convulsive Seizure Clinic of the University of Tennessee College of Medicine, Memphis, has received $1,000 from a mother in memory of her son who had epilepsy. The clinic, which began operation in July in the outpatient department of the city of Memphis Hospitals, is directed by Dr. James G. Hughes, professor of pediatrics.

VERMONT

Lecture on Urology.—The University of Vermont College of Medicine, Burlington, will present "Urologic Problems of the Paraplegic" by Dr. Wyland F. Leadbetter, chief, urologic surgical service, Massachusetts General Hospital, Boston, on Dec. 10, 8 p.m. The college invites all physicians to visit its anatomic laboratory, which is open from 8:30 a.m. to 5 p.m. on weekdays; Saturdays, 8:30 a.m. to 12 noon.

VIRGINIA

Inaugurate President of Medical College.—On Dec. 17 at 11 a.m. Robert B. Smith Jr., Ph.D., will be inaugurated as the fourth president of the Medical College of Virginia, Richmond. Dr. Smith has served as assistant president since 1954. The speaker for the occasion, Joseph C. Robert, Ph.D., president of Hampden-Sydney College, will have as his subject "The Healing Arts and the American Way." Greetings to President Smith will be brought from the student body by Archer K. Tullidge, president; from the faculty by Dr. Frank L. Apperly, professor of pathology; from the alumni association by Dr. James T. Tucker, president; from the Virginia institutions of higher learning by Colgate W. Darden Jr., LL.B., president of the University of Virginia; and from the Commonwealth of Virginia by Governor Stanley.

WEST VIRGINIA

Allergy Clinic.—The first free teaching Allergy Clinic to be established in West Virginia was opened in July at the Ohio Valley General Hospital, Wheeling, with Dr. Martin D. Reiter in charge. The clinic will be used for indigent patients, and Dr. Mayes B. Williams, medical director of the hospital, has agreed that interns and residents in medicine may receive training there in this specialty.

Personal.—Dr. Sarah L. C. Stevens, Huntington, has received a citation from the President's Committee on Employment of the Handicapped for "outstanding services" rendered the handicapped in West Virginia.——Dr. Walter J. Riley, a member of the medical staff at Weston State Hospital, has accepted appointment as senior physician at Laurelton State Village, a state training school for mentally deficient females at Laurelton, Pa.——Governor Marland has reappointed Dr. George F. Evans, Clarksburg, a member of the Medical Licensing Board to serve for five years and Dr. Delivan A. MacGregor, Wheeling, as a member of the West Virginia Board of Health for nine years.——Dr. Ward Wylie, Mullens, who has served as a member of the West Virginia Senate for the past several years, has been reappointed to membership on the State Athletic Commission for a term of three years.

GENERAL

Fellowship for Women Physicians.—The Women's Medical Association of New York announces that the closing date for applications for the Mary Putnam Jacobi Fellowship (THE JOURNAL, July 14, 1956, page 1090) has been postponed to Jan. 1, 1957. This fellowship of $2,000 is open to medical women graduates for postgraduate study or research. Application blanks may be obtained from the Secretary, Dr. Ada Chree Reid, 118 Riverside Dr., New York 24.

Awards for Study in Statistics.—The committee on statistics of the University of Chicago offers awards for studies in statistics by persons whose primary field is not statistics but one of the physical, biological, or social sciences to which statistics can be applied. The awards range from $3,600 to $5,000 on the basis of an 11-month residence. The closing date for application for the academic year 1957-1958 is Feb. 15, 1957. Information may be obtained from the Committee on Statistics, Eckhart Hall, University of Chicago, Chicago 37.

Research in Schizophrenia.—Grants totaling $82,900 for 22 research projects on schizophrenia were recently announced by the National Association for Mental Health. The grants were made from a $100,000 fund provided by the Supreme Council, 33rd Degree, Scottish Rite Freemasonry, Northern Masonic Jurisdiction, which is directing the research program through the National Association for Mental Health. In the last 22 years, the Scottish Rite has provided more than $1,100,000 for this continuing research program.

Fellowship Program.—A senior research fellowship program, administered by the National Institutes of Health, U. S. Public Health Service, will provide during the first year for a total of 40 to 50 awards to the nation's medical schools, dental schools, and schools of public health. These awards will be increased by a like number each year for five years until a total of 200 to 250 such fellowships are awarded annually. The awards will be for a maximum of $10,000 a year and may be retained for as long as five years. Only three applications a year may be made by each school. The program is designed to attract and hold able investigators in the preclinical sciences. Requests for information should be addressed to the Chief, Research Fellowship Program, Division of Research Grants, National Institutes of Health, Bethesda 14, Md.

Schering Award Contest.—The Schering Award Committee, Bloomfield, N. J., invites submission of papers for the 1957 Schering award contest, which is open to all medical students in the United States and Canada. A total of $4,500 in cash prizes will be awarded, twice the amount offered in any previous year. A $1,000 first prize and a $500 second prize will be awarded for the best papers on each of the three selected topics: (1) Incidence of Various Types of Cardiovascular Diseases by Age Group in the Male and the Female; (2) Recent Trends in Corticosteroid Therapy for Ocular Disorders; and (3) Recent Advances in the Biochemical Aspects and Treatment of Mental Disease. Literature and entry forms are being distributed in medical schools. Students interested in participating should submit their entry forms by Jan. 1, 1957.

Guggenheim Fellowship Awards.—Fellowship awards totaling more than $1,100,000 were granted to 275 scholars and artists during 1956 by the John Simon Guggenheim Memorial Foundation, established by the late U. S. senator from Colorado, Simon Guggenheim, and Mrs. Guggenheim in memory of a son, John Simon Guggenheim, who died in 1922. The foundation's fellowships are granted to men and women, without distinction on account of race, color, or creed, who have demonstrated exceptional capacity for original research in all fields of knowledge and artistic creation in all the arts. Its fellowship grants are made to citizens of all the American republics, the Republic of the Philippines, Canada, and the British Caribbean area. The 1956 awards included four each in medicine and medical physics, history of science, microbiology, and genetics.

Association of American Spas.—The Association of American Spas is compiling a directory of American spas that is expected to be ready this year. The executive vice-president, Mr. E. V. Syrcher, 5200 Blackstone Ave., Chicago, writes that the association recently adopted a code of standards that requires medical supervision of spas, and that this is the first time "that a group of health resorts has voluntarily imposed on their operations" standards that require medical supervision. This code was formulated by a committee of which Dr. Neil D. Buie of Marlin, Texas, was chairman and of which Dr. Russell W. Lewis, Sulphur, Okla., and Dr. Euclid M. Smith, Hot Springs, Ark., were members. Among other provisions of the code is one that requires each spa to have a medical supervisor who must be a doctor of medicine residing in the community and who must also be a member of the A. M. A.

Abel Award in Pharmacology.—At the banquet of the American Society for Pharmacology and Experimental Therapeutics the John J. Abel Award in Pharmacology was presented to Fred Warren Schueler, Ph.D., then associate professor of pharmacology in the medical school of the State University of Iowa and, as of July, professor of pharmacology and chairman of the department of pharmacology at the medical school of Tulane University of Louisiana, New Orleans. This annual award, a bronze medal and $1,000 donated by Eli Lilly & Company of Indianapolis, is named in memory of Dr. Abel who occupied the first chair of pharmacology in this country at the University of Michigan, which created the first separate department for this discipline. Dr. Schueler is known particularly for his work on the relationship between chemical structure of drugs and their beneficial and toxic actions.

Fellowships for Ophthalmology Residents.—The Guild of Prescription Opticians of America has named the following physicians as recipients of fellowships for ophthalmology residents in its nationwide program: Miles A. Galin, Brooklyn, at the New York Hospital, New York City; Eugene O. Wiggs, Denver, at Johns Hopkins Hospital, Baltimore; Eugenio De Juan, Aliceville, Ala., at Grady Memorial Hospital, Atlanta, Ga.; Robert V. Spurney, Shaker Heights, Ohio, at University Hospital, Cleveland; Andrew J. Gay Jr., Long Beach, Miss., at McMillan Hospital, Washington University, St. Louis; and Robert K. Langley, Toronto, Canada, at the University of Toronto. The stipend is $1,800. Six additional fellows will be named each year until the permanent total of 18 fellowships is reached, to be maintained permanently at this number by new selections each year to replace fellows completing their residencies.

Tobacco Research Program.—According to the 1956 report of Dr. Clarence C. Little, New York, scientific director of the $1,500,000 research grant program being supported by the Tobacco Industry Research Committee, "well over $1,200,000 in T. I. R. C. funds have been granted to more than 55 scientists who, with their colleagues, are participating in . . . scientific endeavor to help in solving important health questions." Referring to the fields of cardiovascular and coronary disease, Dr. Little said "the uncertainties regarding *cause and even treatment* remain innumerable. . . . Whether smoking has any significant part, and indeed, whether such a part may be positive or negative, is only *one of the many areas in* cardiovascular investigation that should be explored. Preliminary study indicates that the physical, emotional, and mental characteristics of people who become smokers may be of more significance than has been so far recognized."

Fellowships in Gastroenterology.—The department of medicine, University of California School of Medicine, announces two fellowships in gastroenterology at the University of California Medical Center, San Francisco. The fellow has the opportunity to learn gastroscopy and sigmoidoscopy and other gastroenterological techniques and has the responsibility of preparing case presentations before the weekly gastroenterology conference. Opportunities are afforded for participating in the activities of the department relating to general medicine and to other subspecialties of internal medicine through ward rounds and conferences in the specialty clinics. This fellowship, equivalent to a second-or-third-year medical residency and approved by the Board of Internal Medicine, carries a monthly stipend of $150. Information may be obtained from Dr. J. Alfred Rider, Assistant Professor of Medicine, Department of Medicine, University of California Medical Center, San Francisco 22.

Award by Goiter Association.—The American Goiter Association offers the Van Meter Prize award of $300 and two honorable mentions for the best essays submitted concerning original work on problems related to the thyroid gland. The award will be made at the annual meeting of the association in the Hotel Statler, New York, May 28-30, 1957, if essays of sufficient merit are presented in competition. The competing essays may cover either clinical or research investigations; should not exceed 3,000 words; and must be presented in English. Duplicate typewritten copies, double spaced, should be sent to the Secretary, [illegible] John C. McClintock, 149½ Washington Ave., Albany 10, N. Y., not later than Jan. 15, 1957. A place will be reserved on the program of the annual meeting for the presentation of the winning essay by the author. The essay will be published in the annual proceedings of the association.

Course on Surgery of Nasal Septum.—A postgraduate course, "An Introduction to Fundamentals of Reconstructive Surgery of the Nasal Septum and External Pyramid," will be presented at the Yale–New Haven Medical Center by Yale University School of Medicine, department of surgery, section of otolaryngology, in cooperation with the American Rhinologic Society and Grace–New Haven Community Hospital, May 11-18, 1957. The course, under the guest direction of Dr. Maurice H. Cottle, Chicago, will consist of didactic lectures, case presentations, cadaver dissections, and observation of operations. Enrollment is limited. Applicants must be diplomates of the American Board of Otolaryngology (or its equivalent for doctors from other countries). Scholarship assistance is available to a limited number of foreign applicants. For information write the Assistant Dean of Postgraduate Medical Education, Yale University School of Medicine, 333 Cedar St., New Haven 11, Conn.

Prize in Industrial Medicine.—The International Prize Nicolo Castellino Fund offers an award of one million lira (approximately $16,129) for an unpublished study on a scientific research subject freely chosen by the candidate. The contest is open to students of industrial medicine who on May 30 were not more than 35 years of age and were not holders of an official university chair. Seven typewritten copies of each entry must be received by registered post at the fund's Secretariat, at Naples Policlinic, c/o Istitúto di Medicína del Lavoro of Naples University (Piazza Miraglia, Naples, Italy) not later than March 31, 1957. Entries, each bearing a *nom de plume*, must be accompanied by a sealed envelope containing the name of the author and bearing on the outside the relative nom de plume. The entrant must submit a declaration confirming that the paper entered is an original unpublished work not previously entered or awarded a prize in other competitions. The prize will be awarded at the 12th International Congress of Industrial Medicine in Helsinki, Finland, in July, 1957.

EXAMINATIONS AND LICENSURE

BOARDS OF MEDICAL EXAMINERS

ALABAMA. *Examination* Montgomery, June 18-20. Sec., Dr. D. G. Gill, State Office Bldg., Montgomery 4.

ARKANSAS:* *Examination* Little Rock, June. Sec, Dr. Joe Verser, Harrisburg.

CONNECTICUT:* *Examination* New Haven, Mar. 12-14 Sec, Dr. Creighton Barker, 160 St. Ronan St., New Haven.

DELAWARE: *Examination* Dover, Jan. 8-10. *Reciprocity* Dover, Jan 17. Sec., Dr. Joseph S. McDaniel, 225 So State St., Dover.

IDAHO: *Examination and Reciprocity* Boise, Jan. 7-9. Exec. Sec., Mr Armand L. Bird, 364 Sonna Bldg, Boise.

KANSAS: *Examination and Endorsement* Topeka, Dec. 12-13 Sec, Dr Lyle F. Schmaus, 872 New Brotherhood Bldg, Kansas City.

KENTUCKY: *Examination.* Louisville, Dec. 10-12. Sec, Dr. Russell Teague, 620 South Third St., Louisville 2

MARYLAND: *Examination* Baltimore, Dec. 11-14. Sec, Dr. Lewis P. Gundry, 1211 Cathedral St, Baltimore 1.

MASSACHUSETTS: *Examination.* Boston, Jan 15-18. Sec., Dr Robert C Cochrane, State Office Bldg., Boston.

MICHIGAN:* *Examination* Ann Arbor and Detroit, June. Sec, Dr E C. Swanson, 118 Stevens T. Mason Bldg., West Michigan Ave, Lansing 8

MINNESOTA:* *Examination* Minneapolis, Jan. 22-24. *Reciprocity* St. Paul, Feb. 12-13. Sec., Dr. F. H. Magney, 230 Lowry Medical Arts Bldg, St. Paul 2.

MISSISSIPPI. *Reciprocity.* Jackson, December. *Examination* Jackson. June Asst. Sec., Dr. R. N. Whitfield, Old Capitol, Jackson

MONTANA: *Examination and Reciprocity* Helena, Apr 2-3 Sec, Dr. S A Cooney, 214 Power Block, Helena

NEBRASKA:* *Examination* Omaha, June 17-19. Director, Mr. Husted K Watson, Room 1009, State Capitol Bldg., Lincoln 9.

NEW HAMPSHIRE: *Examination and Reciprocity* Concord, March 13-14 Sec., Dr. John S. Wheeler, 107 State House, Concord

NEW JERSEY: *Examination.* Trenton, June 18-21. Sec., Dr. Patrick H. Corrigan, 28 West State St, Trenton.

NEW YORK: *Examination* Albany, Buffalo, New York and Syracuse, Feb 5-8. Sec., Dr. Stiles D. Ezell, 23 S. Pearl St., Albany.

NORTH CAROLINA: *Reciprocity.* Charlotte, Jan. 14. Asst. Sec, Mrs Louise J. McNeill, 716 Professional Bldg, Raleigh.

NORTH DAKOTA: *Examination and Reciprocity* Grand Forks, Jan 2-5 Sec., Dr. C. J. Glaspel, Grafton.

OHIO: *Examination and Reciprocity* Columbus, Dec. 18-20 Sec., Dr H. M. Platter, 21 West Broad Street, Columbus 15.

OKLAHOMA:* *Examination* Oklahoma City, June 11-12. Sec, Dr. E F Lester, 813 Braniff Building, Oklahoma City.

OREGON:* *Reciprocity and Examination.* Portland, Jan. 7-9 Ex. Sec Mr Howard I. Bobbitt, 609 Failing Bldg., Portland 4.

PENNSYLVANIA: Examination, Philadelphia, Jan. 7-10. Act. Sec, Mrs Marguerite G. Steiner, Box 911, Harrisburg.

RHODE ISLAND:* *Examination.* Providence, Jan. 3-4. Administrator, Mr Thomas B. Casey, 366 State Office Bl[illegible]

SOUTH CAROLINA: *Examination and* [illegible] Dec. 11-12. Sec., Mr. N. B. Heyward, 1329 Blanc[illegible]

SOUTH DAKOTA:* *Examination* Sioux Falls, Jan. 21-22. Ex. Sec., Mr. John C. Foster, 30[illegible] National Bank Bldg., Sioux Falls.

TENNESSEE:* [illegible] Dec. 19-20. Sec., Dr. H. W. Qualls, 1635 Exchange Bldg, Memphis 3.

UTAH. *Examination* Salt Lake City, July 11-13. Director, Mr Frank E. Lees, 324 State Capitol Bldg., Salt Lake City 1.

[illegible] *Examination and Reciprocity.* Burlington, Jan. 30, Feb 1. Sec, [illegible]

[illegible] *and Reciprocity* Seattle, Jan 14-16 and Jan 12. Sec., Mr. [illegible] ohm, Olympia.

WEST VIRGINIA: *Examination* Charleston, Jan 7-9. Sec, Dr Newman H Dyer, State Office Building No. 3, Charleston 5.

WISCONSIN:* *Reciprocity* Jan. 9. *Examination* Madison, Jan 8-10 Sec, Dr Thomas W. Tormey, Jr., 1140 State Office Bldg, 1 West Wilson St, Madison.

ALASKA.* On application in Anchorage, Fairbanks, Juneau and other towns Sec., Dr. W. M. Whitehead, 172 South Franklin St, Juneau

GUAM *Subject to Call* Act Sec., Dr. S. F. Provencher, Agana

HAWAII: *Examination.* Honolulu, Jan 14-15. Sec., Dr. I L Tilden, 1020 Kapiolani St., Honolulu

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

CONNECTICUT. *Examination* New Haven, Feb. 9, Exec Asst, Mrs Regina G Brown, 258 Bradley St., New Haven 10.

IOWA. *Examination* Des Moines, Jan 8 Sec, Dr Ben H Peterson, Coe College, Cedar Rapids.

MICHIGAN. *Examination* Detroit and Ann Arbor, Feb 8-9. Sec, Mrs Anne Baker, 116 Stevens T. Mason Bldg, Lansing.

MINNESOTA: *Examination.* Minneapolis, Jan. 8-9 Sec, Dr. Raymond N. Bieter, 105 Millard Hall, University of Minnesota, Minneapolis

NEBRASKA: *Examination.* Omaha, Jan. 8-9 Director, Mr. Husted K Watson, Room 1009, State Capitol Bldg., Lincoln 9.

OKLAHOMA: *Examination.* Oklahoma City, April 19-20 Sec., Dr E. F. Lester, 813 Braniff Bldg., Oklahoma City.

WASHINGTON: *Examination.* Seattle, Jan. 9-10. Sec., Mr. Edward C Dohm, Olympia.

WISCONSIN: *Examination.* Milwaukee, April 6. Sec, Dr. W H. Barber, 621 Ransom St., Ripon

ALASKA: *Examination and Reciprocity.* Anchorage and Juneau, first week of February, April, June, August and November. Sec, Dr. C. Earl Albrecht, Box 1931, Juneau.

*Basic Science Certificate required.

GOVERNMENT SERVICES

SELECTIVE SERVICE SYSTEM

February Call for Physicians.—The director of the Selective Service System, Washington, D. C., issued the following notice to the state directors of Selective Service on Nov. 19:

1. The Secretary of Defense has informed the Selective Service System of an anticipated call for 450 physicians for delivery in February, 1957, 250 for assignment to the Department of the Army and 200 for assignment to the Department of the Air Force.

2. It is requested that each State Director of Selective Service submit to this Headquarters a report on the number of physicians who as special registrants are classified in Class I-A or Class I-A-O, examined, acceptable, and available as of November 20, 1956, to fill the expected call, as follows:

(a) Number of Priority I physicians.
(b) Number of Priority II physicians.
(c) Number of Priority III physicians born on or after January 1, 1919, by each year of birth as follows:

1919
1920
1921
1922
1923
1924
1925
1926
1927
1928
1929
1930
1931
1932
1933

(d) *Exclude from this report:*

(1) Physicians who will be 46 years of age or older on February 27, 1957.
(2) Physicians who will be 35 years of age or older on February 27, 1957, and have applied at any time for a commission in one of the armed forces in a medical, dental, or allied specialist category and have been rejected for such commission solely because of physical disqualification.

3. The report requested in paragraph 2 of this advice should be submitted by fastest mail so as to reach this Headquarters not later than December 4, 1956.

Lewis B. Hershey
Director

AIR FORCE

Consultants Visit European Installations.—U. S. Air Force medical consultants left Washington, D. C., Nov. 5 to visit U. S. Air Force medical installations in Europe and to attend the U. S. Air Force in Europe medical conference in Wiesbaden, Germany, Nov. 20-21. The group included Dr. Clarence C. Pearson, of the Mason Clinic, Seattle, and Dr. James J. Callahan, of the Callahan Clinic, Chicago, consultants to the surgeon general in internal medicine and orthopedic surgery, respectively; Col. Don. S. Wenger, deputy director, professional services, office of the surgeon general; and Col. Archie A. Hoffman, chief, consultants group, office of the surgeon general.

Promotion of Senior Officers.—The Air Force has announced the promotion of several senior medical service officers. Olin F. McIlnay, director of plans and hospitalization, office of the surgeon general, and Otis O. Benson, commandant, school of aviation medicine, Randolph Air Force Base, Texas, were promoted from the rank of brigadier general to that of major general. Victor A. Byrnes, director of professional services, office of the surgeon general, and John R. Copenhaver, surgeon, Alaskan Air Command, were promoted from the rank of colonel to that of brigadier general.

NAVY

Dedicate Memorial to Hospitalman.—In a ceremony at Alexandria, Va., Nov. 15, a new high school was dedicated to the memory of Navy Hospitalman Francis C. Hammond, Medal of Honor winner. Rear Adm. Irwin Norman, assistant chief, bureau of medicine and surgery; Capt. Willard Calkins, chief, Medical Service Corps; city, county, and state officials; members of the Virginia Board of Education; and representatives of civic and civilian military organizations participated in the dedication. A native of Alexandria, Hammond was awarded the Medal of Honor posthumously. The citation read in part as follows:

> For conspicuous gallantry beyond the call of duty as a Medical Corpsman, serving with the First Marine Division in Korea on March 26-27, 1953. During a counter-attack against an entrenched and numerically superior hostile force occupying commanding ground on a bitterly contested outpost far in advance of the main line of resistance, Hammond's platoon was subjected to hostile mortar and artillery fire, followed by an assault by enemy troops. Advancing through the veritable curtain of fire to aid his stricken comrades, he moved among the garrison of Marines and, although critically wounded, continued to administer aid to the other wounded throughout an exhausting four-hour period. When the unit was ordered to withdraw, he skilfully directed the evacuation of casualties and remained in the fire-swept area to assist the corpsmen until he was struck by enemy mortar fire and fell, mortally wounded. By his exceptional fortitude, inspiring initiative and self-sacrificing efforts, Hammond undoubtedly saved the lives of many Marines. His valor in the face of overwhelming odds enhances and sustains the finest traditions of the United States Naval Service. He gallantly gave his life for his country.

Hospitalman Hammond's widow and son reside in Alexandria, Va.

VETERANS ADMINISTRATION

Orthopedic Shoe Service for Veterans.—The Veterans Administration announced Nov. 9 that its orthopedic shoe services have been centralized in New York City. The centralization will result in more satisfactory repairs and in savings of about $12 per pair on thousands of new shoes annually furnished veterans with foot disabilities. The orthopedic shoe section of the VA prosthetics center in New York stores the individual lasts and patterns from which orthopedic shoes are made by private contractors for some 10,000 veterans in the 48 states. The section also has started a national repair program for orthopedic shoes. In addition to storing the individual lasts and patterns from which new orthopedic shoes are made, the New York center instructs private contractors in details of construction, checks the shoes after they are made, and sends them on to the veterans.

Now, after receiving instructions and a mailing carton from the VA, a veteran anywhere in the country can mail his old orthopedic shoes to the New York center and within two weeks or less receive them relasted and refinished. This expert repairing, it is said, not only reduces the number of new shoes needed but helps insure that each veteran will receive the correct type of repairs for his particular foot condition.

PUBLIC HEALTH SERVICE

Study of Nutrition in Other Countries.—Dr. Frank B. Berry, Assistant Secretary of Defense, Health and Medical, and his group were expected to return Nov. 21 from a tour of countries in Europe and the Middle East where nutritional problems and dietary deficiencies were studied. Stopovers were made at Paris, France; Athens, Greece; Istanbul, Ankara, and Izmir, Turkey; Beirut, Lebanon; Port Lyautey, French Morocco; Teheran, Iran; Karachi, Pakistan; Asmara, Eritrea; Addis Ababa, Ethiopia; and Tripoli, Libya.

Accompanying Dr. Berry were Rear Adm. Bartholomew Hogan, surgeon general of the Navy; Major Gen. James O. Gillespie, from the office of the Army surgeon general; Major Gen. Harry Armstrong, surgeon in the Air Force; Dr. Arnold E. Schaefer, deputy director, Interdepartmental Committee on Nutrition for National Defense; Dr. Joseph S. Butte, from Oregon State College, Corvallis, Ore., and consultant to the Interdepartmental Committee; Dr. Olaf Mickelsen, of the National Institutes of Health, Washington, D. C.; Dr. Richard A. Kern, from Temple University Hospital, Philadelphia; Dr. Edward A. Churchill, professor of surgery, Harvard University, Cambridge, Mass.

While on this trip the group also surveyed medical care provided for U. S. Military Assistance Advisory Groups (MAAG) in the areas visited. Lieut. Commander Thomas L. Hollis, U. S. Navy, executive assistant to Admiral Hogan, was project officer to the group for the 28-day trip.

DEATHS

Dear, William Richard ⊕ Brigadier General, U. S. Army, retired, Washington, D. C.; born in Hamilton, Va., Dec. 7, 1883; University of Pennsylvania Department of Medicine, Philadelphia, 1906; interned at the Central Dispensary and Emergency Hospital; in 1908 commissioned a first lieutenant in the Medical Corps of the U. S. Army and the following year graduated with honors from the Army Medical School; began his military career as a medical officer at outposts in China and the Philippines; during World War I returned to the United States and commanded Army base hospitals at Camp Lee in Camp Lee, Va., and Fort Wadsworth in Rosebank, Staten Island, N. Y.; at the end of World War I assigned to Germany as the chief surgeon of the American Expeditionary Forces; from 1921 to 1923 medical and sanitary director of the American Relief Association in Kazan, Russia; there he directed relief and public health work for the Hoover Relief Mission; between wars served with the office of the Army surgeon general, Washington, D. C.; in 1927 assigned as assistant professor of military science and tactics at his alma mater, where for five years he was head of the Reserve Officers Training Corps unit; during this period commanded the ROTC summer camp at Carlisle, Pa.; from 1932 to the outbreak of World War II served as surgeon at various Army posts in the United States; in April, 1941, after his promotion to brigadier general, was placed in charge of the Medical Replacement Training Center at Camp Lee, Va.; in 1943 became the commanding general of the Northington General Hospital, Tuscaloosa, Ala., where he remained until retirement Aug. 31, 1946; was awarded the Army Commendation Ribbon and the Legion of Merit; member of the House of Delegates of the American Medical Association in 1931; fellow of the American College of Surgeons; a track star in his youth; died in the Walter Reed Army Hospital Sept. 7, aged 72, of arteriosclerosis.

Noble, Robert Ernest ⊕ Major General, U. S. Army, retired, Anniston, Ala.; born in Rome, Ga., Nov. 5, 1870; Columbia University College of Physicians and Surgeons, New York City, 1899; entered the U. S. Army in 1901 as an assistant surgeon; early military service included three years in the Philippine Islands; honor graduate of the Army Medical School in 1904; from 1907 to 1914 served in Panama Canal Zone, in association with Col. William C. Gorgas in the eradication of yellow fever during construction of the canal; during his assignment there, was detailed to mosquito control work in Puerto Rico and Ecuador, and in 1913-1914 was a member of the Commission to Rand Mines, Transvaal, South Africa, studying the causes of pneumonia; following completion of the Panama Canal returned to Washington and was in charge of Medical Corps personnel; went with the American Expeditionary Force to France, returning in 1919 to become librarian of the Army Medical Library; promoted to brigadier general in 1919 when he became assistant surgeon general; in 1920 became a member of the International Health Board Commission of the Rockefeller Foundation studying yellow fever in West Africa and, when General Gorgas died, became chairman; retired Feb. 8, 1925; awarded the Distinguished Service medal; was a commander of the French Legion of Honor; member of the House of Delegates of the American Medical Association, 1917-1918; fellow of the American College of Surgeons; served as president of the Choccolocco Council of the Boy Scouts of America; for his work with the Boy Scouts won the Silver Beaver and the Silver Antelope; was named by the Anniston *Star* as "Man of the Year" for 1955, honoring a long career of devoted service to his country and his community; died in Fort McClellan Sept. 18, aged 85, of bronchopneumonia.

Hibben, John Severy, Pasadena, Calif.; born in Topeka, Kan., in 1888; College of Physicians and Surgeons, Los Angeles, 1914; an associate member of the American Medical Association; fellow of the American College of Physicians; member of the American Society of Physical Medicine and Rehabilitation; past-president of the American Congress of Physical Therapy; specialist certified by the American Board of Physical Medicine and Rehabilitation; from 1917 to 1922 health officer of Pasadena; a founder of the Woman's Hospital; local physician for the Atchison, Topeka and Santa Fe Railway and the Union Pacific Railway; on the staffs of the Alta Vista Hospital, St. Luke Hospital, and the Collis P. and Howard Huntington Memorial Hospital, where he died Sept. 30, aged 68, of cerebral thrombosis, diabetes mellitus, and hypertension.

Potter, Irving W., Buffalo, born in Buffalo, Nov. 12, 1868, University of Buffalo School of Medicine, Buffalo, 1891, specialist certified by the American Board of Obstetrics and Gynecology, member of the American Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; an associate member of the American Medical Association; past-president of the Erie County Medical Society and the Buffalo Academy of Medicine; author of "The Place of Version in Obstetrics"; consultant, New York Polyclinic Medical School and Hospital in New York City, Deaconess Hospital, Buffalo City Hospital, Lafayette General Hospital, and the Millard Fillmore Hospital, where he died Sept. 17, aged 87, of uremia.

Gage, George Henry, Rochester, N. Y., born in Benton, April 22, 1880; Columbia University College of Physicians and Surgeons, New York City, 1903; an associate member of the American Medical Association; fellow of the American College of Surgeons and the International College of Surgeons; won the Distinguished Service medal and the Croix de Guerre for service during World War I; member of the staff of the Park Avenue Hospital, where he was for many years president of the board; past-president of the Medical Society of the County of Monroe and the Rochester Pathological Society; died in the Park Avenue Hospital Sept. 12, aged 76, of acute coronary occlusion.

Metcalf, Walter Bradford ⊕ Los Altos, Calif.; born in Marengo, Ill., Jan. 3, 1867; Northwestern University Medical School, Chicago, 1894; member of the Illinois State Medical Society, specialist certified by the American Board of Internal Medicine, fellow of the American College of Physicians; at one time practiced in Chicago, where he was on the faculty of the University of Illinois College of Medicine and on the staff of the Cook County Hospital and consulting physician at the City of Chicago Municipal Tuberculosis Sanitarium; past-president of the Chicago Tuberculosis Association; died Sept. 2, aged 89, of carcinoma of the prostate with metastasis to both lungs.

Judovich, Bernard Davis ⊕ Philadelphia; born in Philadelphia, July 7, 1904; Hahnemann Medical College and Hospital of Philadelphia, 1930; associate in neurology at the Graduate School of Medicine of the University of Pennsylvania; joint author of "Pain Syndromes" and "Segmental Neuralgia in Painful Syndromes", on the staffs of the Hospital of the Woman's Medical College of Pennsylvania and the Graduate Hospital of the University of Pennsylvania, where he was founder and head of the Pain Research Foundation and where he died Sept. 13, aged 52, of myocardial infarction.

Allen, Lloyd Raymond ⊕ Colorado Springs, Colo.; Northwestern University Medical School, Chicago, 1903; veteran of World War I, served as treasurer of the Colorado State Medical Society, on the staffs of the Memorial Hospital, St. Francis Hospital, and the Glockner-Penrose Hospital, where he died Sept. 16, aged 77, after gastric resection for a duodenal ulcer.

Ashley, Samuel Glick ⊕ Chanute, Kan.; University Medical College of Kansas City, Mo., 1908; died in the Neosho Memorial Hospital Sept. 17, aged 74, of cerebral hemorrhage.

Baker, Robert Harper ⊕ Pontiac, Mich.; University of Michigan Medical School, Ann Arbor, 1916; served on the council of the Michigan State Medical Society and in 1955 its president; at one time on the faculty of his alma mater; fellow of the American College of Surgeons; past-president, secretary, and treasurer of

---

⊕ Indicates Member of the American Medical Association.

the Oakland County Medical Society; veteran of World War I; on the staff of the Pontiac General Hospital, where he died Sept. 6, aged 64, of cancer.

Ball, James Austin ⚕ Charleston, S. C.; Medical College of South Carolina, Charleston, 1900; served on the faculty of his alma mater; died Sept. 16, aged 81, of acute myocardial infarction.

Berger, Samuel Sylvester ⚕ Cleveland; Western Reserve University Medical Department, Cleveland, 1904; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the board of trustees of the American College of Gastroenterology; on the staffs of the St. Luke's Hospital and the Mount Sinai Hospital, where he died Sept. 18, aged 74, of coronary disease.

Boyer, George Milton, Damascus, Md.; Columbian University Medical Department, Washington, D. C., 1902; veteran of World War I; a trustee of the Damascus School; past-president of the Montgomery County Medical Society; an associate member of the American Medical Association; on the staff of the Frederick (Md.) Memorial Hospital; a director and vice-president of the Bank of Damascus; died Sept. 21, aged 84.

Boylan, Thomas Edward, Fall River, Mass.; University of Vermont College of Medicine, Burlington, 1898; medical examiner for Bristol County district 3; served as a member of the school committee; for many years city physician; member of the board of examining physicians during World War I draft; on the staffs of the Union Hospital, Truesdale Hospital, Fall River General Hospital, and the St. Anne's Hospital, where he died Sept. 29, aged 86.

Bunch, James Ralph ⚕ Nevada, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1916; fellow of the American Psychiatric Association; veteran of World War I; at one time superintendent of the State Hospital No. 1 in Fulton; on the staff of the State Hospital No. 3, where he died Sept. 29, aged 68, of coronary sclerosis.

Buntin, Hansford H. ⚕ Carlisle, Ky.; Kentucky School of Medicine, Louisville, 1891, served on the county board of health; died in the Good Samaritan Hospital, Lexington, Sept. 2, aged 88, of cancer.

Bush, S. Warren, Parkersburg, W. Va.; Baltimore University School of Medicine, 1901; died in the Camden-Clark Memorial Hospital Sept. 18, aged 89, of carcinoma.

Calvert, William Clinton ⚕ West Orange, N. J.; New York Homeopathic Medical College and Flower Hospital, New York City, 1929; veteran of World War II; member of the Association of Military Surgeons of the United States; physician for West Orange schools; on the staffs of the Kessler Institute for Rehabilitation in West Orange, Montclair Community Hospital in Montclair, Orange (N. J.) Memorial Hospital, and the East Orange (N. J.) General Hospital; died in Cutchogue, N. Y., Sept. 29, aged 53, of cerebral hemorrhage.

Cheves, William Grey, Franklinton, N. C.; Jefferson Medical College of Philadelphia, 1925; served as medical director of the state prison system at Raleigh; on the staff of the Franklin Memorial Hospital in Louisburg, where he died Sept. 10, aged 54, of coronary thrombosis.

Collier, Joel Isham ⚕ Navasota, Texas; University of Texas School of Medicine, Galveston, 1907; died in the Baptist Memorial Hospital, Memphis, Tenn., Sept. 1, aged 76, of coronary occlusion.

Davis, John McMillin, Darlington, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1895; served as county coroner; an associate member of the American Medical Association; died Sept. 3, aged 84, of pulmonary edema and arteriosclerotic heart disease.

Davis, Leonard Henry, Milledgeville, Ga.; Medical College of Georgia, Augusta, 1952; interned at the University Hospital in Augusta, Ga., and the Spartanburg (S. C.) General Hospital; district director of the health department; veteran of World War II; died Aug. 26, aged 29, of a heart attack.

Dill, John Robert, Rising Star, Texas; Memphis Hospital Medical College, Memphis, Tenn., 1906; also a druggist; served as health officer; died in Gorman Aug. 26, aged 80, of chronic nephritis.

Donohue, Michael Joseph ⚕ Antigo, Wis.; Northwestern University Medical School, Chicago, 1898; chief of staff at the Langlade County Memorial Hospital; died Aug. 24, aged 82, of virus pneumonia.

Eddy, John D., Morrilton, Ark.; University of Arkansas School of Medicine, Little Rock, 1902; died Sept. 14, aged 92, of heart disease.

Elkins, Charles Edward, Massena, N. Y.; University and Bellevue Hospital Medical College, New York City, 1903; an associate member of the American Medical Association; veteran of World War I; for many years health officer; died in the A. Barton Hepburn Hospital, Ogdensburg, Aug. 9, aged 79.

Ely, George Winfrid, Pittsburgh; Bellevue Hospital Medical College, New York City, 1894; an associate member of the American Medical Association; veteran of the Spanish-American War; at one time a member of the medical department of the public schools; served on the staffs of St. Francis and the Western Pennsylvania hospitals; died Sept. 18, aged 84, of cerebral hemorrhage.

Fowler, William West ⚕ Dallas, Texas; Memphis Hospital Medical College, Memphis, Tenn., 1903; for many years secretary of the Dallas County Medical Society; served as editor of the *Dallas Medical Journal*; died Sept. 10, aged 84, of coronary occlusion.

Grussner, Alfred Sethell ⚕ Schenectady, N. Y.; Medical College of Virginia, Richmond, 1918; fellow of the American College of Surgeons; veteran of World War I; on the staff of the Ellis Hospital, where he died Sept. 12, aged 63, of acute coronary occlusion.

Heckert, Emerson Monroe ⚕ Sunbury, Pa.; Jefferson Medical College of Philadelphia, 1921; veteran of World War I; on the staff of the Sunbury Community Hospital, where he died Aug. 30, aged 65, of coronary infarction.

Henning, Carl ⚕ Rehoboth Beach, Del.; George Washington University School of Medicine, Washington, D. C., 1905; member of the Medical Society of the District of Columbia and the American Academy of Ophthalmology and Otolaryngology; veteran of World War I; for many years practiced in Washington, D. C., where he was on the staff of the Episcopal Eye, Ear and Throat Hospital; died Sept. 12, aged 76, of congestive heart failure.

Hicks, George Amos, Rochester, N. Y.; University of Buffalo School of Medicine, Buffalo, 1916, member of the Medical Society of the State of New York, served on the staff of St. Mary's Hospital; died Sept. 13, aged 70, of coronary occlusion.

Hilton, George Francis ⚕ Garden Grove, Calif.; Central Medical College of St. Joseph, Mo., 1898, member of the Washington State Medical Association; practiced in Wenatchee, Wash., where he was on the staffs of the Central Washington Deaconess and St. Anthony's hospitals; died Aug. 8, aged 80, of Hodgkin's disease.

Hoke, Samuel Erle ⚕ Meadville, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1927; past-president and secretary of the Crawford County Medical Society; served as director of health services at Allegheny College; on the staffs of the Spencer Hospital and the Meadville City Hospital, where he died Sept. 25, aged 54, of coronary occlusion.

Indovina, Vincenzo, Chicago; Regia Università degli Studi di Palermo. Facoltà di Medicina e Chirurgia, Italy, 1893; on the staff of the Mercy Hospital; died Oct. 11, aged 89.

Iseminger, Sidney Willis ⊕ Bakersfield, Calif.; University of Southern California School of Medicine, Los Angeles, 1941; specialist certified by the American Board of Radiology; member of the Radiological Society of North America and the American College of Radiology; president of the Kern County Heart Association; served as secretary-treasurer and vice-president of the Kern County Medical Society; on the staffs of the Mercy Hospital and the Kern General Hospital; died Sept. 29, aged 41, of myocardial infarction.

Jablow, Harry B. ⊕ Dallas, Texas; University of Louisville Medical Department, Louisville, Ky., 1911; veteran of World War I; died Sept. 23, aged 67, of heart disease.

Keeler, Russell Raudenbush ⊕ Harleysville, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1912; veteran of World War I; died Aug. 17, aged 67, of carcinoma of the tongue with metastases.

Key, Samuel Newton ⊕ Austin, Texas; University of Texas School of Medicine, Galveston, 1910; specialist certified by the American Board of Otolaryngology; life member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past-president of the Travis County Medical Society; formerly secretary and member of the board of trustees of the Texas Medical Association; on the staffs of the Seton and St. David's hospitals; died Sept. 3, aged 70, of cerebrovascular accident.

Killingsworth, Laura Anna U. Penn, Washington, D. C.; Howard University College of Medicine, Washington, D. C., 1908; for many years on the staff of the Freedmen's Hospital, where she was emeritus assistant in gynecology at the outpatient department and where she died Sept. 20, aged 74, of acute myocardial infarction and hypertension.

ing, Samuel, Warren, Pa.; Hospital College of Medicine, Louisville, Ky., 1902; died Sept. 16, aged 90, of cerebral hemorrhage.

Kirkle, Orval LeRoy, West Sacramento, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1931; died in Oakland Aug. 18, aged 61, of arteriosclerotic heart disease.

Knorr, John Keyser, Jr., Wayne, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; veteran of World War I; died in the Lankenau Hospital, Philadelphia, Sept. 18, aged 78, of cerebrovascular accident.

Levitas, George Max, Westwood, N. J.; Long Island College Hospital, Brooklyn, N. Y., 1904; an associate member of the American Medical Association; fellow of the American College of Physicians; past-president of the Bergen County Medical Society; served on the staff of the Hackensack (N. J.) Hospital and on the board of governors of the Bergen Pines County Hospital in Paramus; died Sept. 17, aged 74.

Londergan, James Patrick, Providence, R. I., Georgetown University School of Medicine, Washington, D. C., 1930, member of the Rhode Island Medical Society, veteran of World War II, on the staff of the Roger Williams General Hospital and St. Joseph's Hospital; died Sept. 5, aged 54, of carcinoma of the tongue.

Love, Francis Leonard ⊕ Iowa City, Iowa, State University of Iowa College of Medicine, Iowa City, 1906, served as city health officer; on the staff of the Mercy Hospital, where he died July 21, aged 77, of carcinoma of the sigmoid.

McCoy, Clayton Lloyd, Hastings, Pa., Jefferson Medical College of Philadelphia, 1915; an associate member of the American Medical Association; veteran of World War I, on the staff of the Miners' Hospital of Northern Cambria in Spangler; died Sept. 6, aged 68.

Martin, Claude Alexander, Welsh, La., University of Louisville Medical Department, Louisville, Ky., 1912; an associate member of the American Medical Association, served on the town council and board of health; past-president of the Jefferson Davis Parish Medical Society; veteran of World War I and was awarded the Distinguished Service Cross, also won the French Croix de Guerre with two Silver Stars, the Purple Heart medal, and five battle citations; on the staff of St. Patrick's Hospital in Lake Charles, died Sept. 16, aged 73, of heart disease.

Menzies, Robert Campbell, Chicago; Rush Medical College, Chicago, 1905; died Sept. 23, aged 74.

Michie, Henry Clay, Jr. ⊕ Colonel, U. S. Army, retired, San Antonio, Texas; University of Virginia Department of Medicine, Charlottesville, 1907; fellow of the American College of Physicians; entered the Medical Corps of the U. S. Army in 1911, veteran of World War I; retired Feb. 25, 1946; died Aug. 4, aged 74, of heart disease.

Nelson, John Albert, Sr., Tekoa, Wash.; University of Nashville Medical Department, Nashville, Tenn., 1902, served as city health officer; formerly associated with the Indian Service, died Sept. 17, aged 81, of cardiac decompensation, nephrosclerosis, and uremia.

Nolan, Charles Aloysius J., Brooklyn, N.Y., Long Island College Hospital, Brooklyn, 1924, member of the Medical Society of the State of New York; died Sept. 29, aged 60.

O'Connor, John Vincent ⊕ Woonsocket, R. I.; College of Physicians and Surgeons, Baltimore, 1911; past-president of the Woonsocket District Medical Society; on the staff of the Woonsocket Hospital; died Sept. 14, aged 71, of arteriosclerosis and myocardial infarction.

Parsons, John Purl ⊕ Grosse Pointe Park, Mich.; University of Michigan Medical School, Ann Arbor, 1919; interned at the University Hospital, Ann Arbor; for two years resident in internal medicine at the Massachusetts General Hospital, Boston; formerly on the faculty of his alma mater; past-president of the Michigan State Medical Society; member of the American Academy of Pediatrics and the American Academy of Allergy; died Sept. 17, aged 67, of pneumonia.

Pirrung, Joseph Edward, Cincinnati; Miami Medical College, Cincinnati, 1906; fellow of the American College of Surgeons, veteran of World War I; died in the Veterans Administration Hospital, Lexington, Ky., Aug. 24, aged 73.

Quisito, Joseph Michael ⊕ Trenton, Mo.; Kansas City University of Physicians and Surgeons, Kansas City, Mo., 1932, member of the American Academy of General Practice; veteran of World War II; on the staff of the Wright Memorial Hospital, died Oct 2, aged 50, of heart disease.

Roberson, James Franklin, St. Jo, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1886, died in Fort Worth Aug. 9, aged 101, of arteriosclerosis.

Robson, Theodore Thomas ⊕ Seattle; Middlesex College of Medicine and Surgery, Cambridge, Mass., 1917; on the staff of the Doctors Hospital, where he died Sept. 17, aged 69.

Roll, Albert Thomas ⊕ Louisville, Ky.; University of Louisville School of Medicine, Louisville, Ky., 1916; formerly practiced in Puumaile and Hilo Memorial Hospital in Hilo, Hawaii, on the staff of the Veterans Administration Hospital; died in the Jewish Hospital Aug. 23, aged 75, of coronary heart disease and hypertension.

Rosenthal, George ⊕ Cherry Valley, N.Y., Universitat Heidelberg Medizinische Fakultat, Baden, Germany, 1910, died Aug. 23, aged 70, of myocardial infarction and coronary arteriosclerosis

Sellers, Frank Este ⊕ Captain, U. S. Navy, retired, San Diego, Calif., University of Virginia Department of Medicine, Charlottesville, 1901; entered the Medical Corps of the U. S. Navy in 1905; retired Sept. 1, 1939, fellow of the American College of Surgeons, died Sept. 13, aged 80

FOREIGN LETTERS

AUSTRIA

Iron Metabolism.—At the meeting of the Society for Pediatrics in Vienna on June 5, Dr. Weippl described the difference between normal iron metabolism in infants and adults. In the infant the amount of iron stored is constantly increasing. Therefore, the absolute iron requirement (in milligrams) is higher in the infant than in the adult, and the relative requirement (in per cent) is even higher. As illustrative cases, the speaker presented the histories of an infant with masked sideropenia who had no anemia despite a severe deficiency of iron and who made a good response to treatment with iron; an infant with a simple alimentary iron deficiency anemia, which, in children, can be almost normochromic; a child with a severe hypochromic anemia, deficient iron absorption, achylia, and a tendency to relapse; a patient with symptomatic polyglobulism and the tetralogy of Fallot who had an increased erythrocyte count and an increase in the serum iron level (despite cyanosis in such a patient, iron therapy may be recommended to strengthen the performance of the heart); a 4-year-old child with acquired hemolytic anemia who did not respond to any therapy and in whom autopsy revealed an excessive siderosis without evidence of hemochromatosis; and an 18-month-old dystrophic anemic child whose anemia was caused by protein deficiency and who was given protein parenterally and by mouth. In this last patient the weight increased and there was normalization of the iron metabolism. The anemia disappeared, but the increase in erythrocytes led to an iron deficiency.

Epidemiology of Poliomyelitis.—At the combined scientific meeting of the Austrian Society of Microbiology and Hygiene and of the Vienna Pediatric Society in May, Dr. H. H. Radl stated that unusual features in the epidemiology of poliomyelitis in the last two years were the increase in the number of cases of the bulbar form and the large number of cases observed from October to December. In 1955 there was an unusually high percentage of contact cases (42.5%). H. P. Krepler reported on a "house-epidemic" in a children's hospital and particularly in the ward for infants, where seven cases of nonparalytic poliomyelitis—two meningeal, three abortive, and two unapparent—were detected and their cause established by identification of poliomyelitis virus type 1 in the feces and neutralizing antibodies in the serum. The same virus was found in the stools of a nurse. Subsequently, in an adjacent ward for internal diseases, a 6-year-old girl who had been hospitalized for several months became severely ill with bulbospinal poliomyelitis 11 weeks after tonsillectomy. A 5-year-old boy, who had a tonsillectomy at the same time, and a 4-year-old boy, who had one a month later, in the completely separated otolaryngological ward, became severely ill 11 days later with bulbar poliomyelitis. One child died.

H. H. Zischinsky stated that house epidemics of poliomyelitis are rare but have been observed at the Wilhelminen Hospital, where they occurred exclusively in the pertussis ward. The first case was seen in the summer of 1949. At this time, 6 of the 14 children on the ward contracted some form of poliomyelitis. A second epidemic occurred in August, 1955, when four cases of poliomyelitis were found in one pavilion of the department of internal medicine. The patients had been admitted with vague symptoms and were moved after the diagnosis was made. In September, one case of paretic poliomyelitis occurred in this pavilion among the children with pertussis, all of whom had already been hospitalized for several weeks. Careful clinical and spinal fluid examinations did not reveal any evidence of poliomyelitis among the other exposed children. In October, the ward was again filled with victims of pertussis, who remained free of poliomyelitis, but, in November, new victims of pertussis were admitted, after all the previous victims had left, whereupon paretic poliomyelitis developed in a child who had been in the hospital for five weeks. Of the 21 exposed children only 3 escaped infection with the virus. All but the first victim had only mild symptoms and slight changes in the spinal fluid. Investigation revealed poliomyelitis virus type 1 in a nurse. Since no other source of infection was ascertainable for these children, who had been hospitalized for weeks before the onset of their poliomyelitis, it is assumed that the nurse, by taking care of the first victims in August, had become a carrier and thus caused the house epidemic. Since such epidemics have been seen only in children with pertussis, it would seem that pertussis produces a definite predisposition to poliomyelitis and that the house epidemic was favored by the increased opportunity for group contact.

H. P. Kraus stated that he isolated 17 virus strains of type 1 (Brunhilde) from 61 stool specimens of patients and contacts of the two house epidemics reported. This would indicate that the same type of causative agent can be found in epidemics with different courses. The serologic examinations (demonstration of virus-neutralizing antibodies) confirm the types, which were identified by culture. An increase in antibodies could be demonstrated in three children, who had contact with poliomyelitis victims but did not show an increased cell count in the fluid. This suggests that viremia, which occurs in the course of an unapparent infection, does not necessarily lead to infection of the central nervous system.

INDIA

Fellowships for Indian Professors.—Five special fellowships have been awarded to Indian professors by the World Health Organization to study preventive and social medicine at the Harvard School of Public Health. These fellowships form part of the medical education program established by the government and WHO in which the teaching of preventive and social medicine in undergraduate medical courses is to be given greater emphasis.

The Indian Public Health Association.—The Indian Public Health Association has been formed under the chairmanship of the director-general of health services. It will afford a means of communication between the thousands of public health workers throughout the country and will publish quarterly the *Indian Journal of Public Health.*

Soft Tissue Sarcomas.—M. V. Sirsat reported a series of 146 patients with soft tissue sarcomas of the extremities and trunk (*Indian Journal of Surgery,* August, 1956). Fibrosarcomas ranked first in frequency and formed 60.3% of the soft tissue sarcomas. Of these, 75% occurred in patients between the ages of 30 and 50 years (average 38.8). The thigh was the commonest site. Local recurrence was observed in 73.9%, this high rate being due to inadequate initial surgical treatment. Rhabdomyosarcoma of skeletal muscle formed 20.5% of soft tissue sarcomas in this series. Most of these patients were between 41 and 50. It showed a definite predilection for the lower extremity and especially the thigh muscles, which were involved in 30% of the patients. Rhabdomyosarcomas and synovial sarcomas have a poor prognosis. Patients with undifferentiated sarcomas run a rapid downhill course, with early appearance of pulmonary metastases. Other types met with included lipogenic sarcoma, reticulum cell sarcoma, and angiosarcoma. Biopsy helps in planning correct treatment. The line of incision in surgical excision of the tumor must pass at least 3 cm. outside the palpable limits of the tumor at all points.

Lymphangiography in Scrotal Filariasis.—U. S. Arora and co-workers (*Bulletin of the Calcutta School of Tropical Medicine,* July, 1956) reported the use of lymphangiography to determine the presence of lymphatic obstruction and its site, nature, and extent in six patients with scrotal filariasis. The duration of the illness varied from 3 to 14 years. Microfilaria bancrofti was found in the peripheral blood as well as in the lymph aspirated from the dilated scrotal lymphatics in two patients and in two others

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

it was found only in the scrotal lymph. Ten cubic centimeters of a radiopaque dye was injected percutaneously into a suitable dilated scrotal lymph vessel. No untoward reactions were noted. The lymphatics were well visualized in all cases. In four patients the filling was unilateral and in the other two bilateral. The presence of obstruction was shown in all by the dilated tortuous intercommunicating lymphatic vessels with regional filling defects. The site of obstruction in all appeared to be at about the level of the superficial inguinal lymph nodes of the side injected.

Health Education.—At the meeting of the southeast Asia regional committee of the World Health Organization in Delhi in September, Lieut. Col. T. C. Puri (India) stressed the importance of health education in southeast Asia, where ignorance, poverty, and other socioeconomic conditions were responsible for so much preventable disease. He said that the school child should receive special priority because he is easily accessible and the school teacher could give the necessary instructions. Through the school child, knowledge of health could be introduced into the home and thence the neighborhood, and when the child grew up he would have a constructive attitude on matters of health.

Medical Services in Assam.—A steady progress in medical services in Assam is recorded in an official report. The number of hospitals and dispensaries has risen from 408 in 1951 to 453 in 1955 and the number of beds from 2,520 to 2,624. Extensive repairs and expansion have been carried out in the five local board hospitals. Provision was made to increase the number of beds in these hospitals from 100 to 200 and to install modern equipment, such as x-ray machines. The five district hospitals were provided with x-ray machines and other modern equipment in the past year. Further expansion by adding 25 general beds and 20 beds for tuberculous patients in each of these hospitals was approved by the planning commission under the second five-year plan. Other smaller hospitals and institutions will also receive necessary aid. The Gauhati Ayurvedic College, the only institution of its kind in Assam, has established a research department. A new training center for auxiliary nurses and midwives has been opened.

SWEDEN

Effects of the Free Sale of Alcohol.—Up to Oct. 1, 1955, spirits were rationed in Sweden, only wine and beer being obtainable without serious restrictions. After this date, Swedes were freely allowed to buy as much alcohol as they pleased. The statistics for the first half year of this experiment show a marked rise in the sale of spirits and the number of arrests for drunkenness. In May, 1955, the number of such arrests was 768, whereas the corresponding number for May, 1956, was 2,272. In Stockholm, the rate of occurrence of delirium tremens has more than doubled, and the public asylum at Beckonberga has been unable to accommodate all the applicants for admission for alcoholism.

Doctors and Journalists at Variance.—Because of growing disagreement between the medical profession and the lay press, the Swedish Publicist Club invited representatives of the medical profession to present their viewpoint and to listen to that of journalists and editors. *Svenska Lakartidningen* for September gives a report of this discussion. Dr. Justus Strom pointed out that the relations between himself and the lay press had on the whole been cordial, but that they had lately been marred by an incident when a journalist had reported on a patient in such a way as to put Strom in a false light. While private medical practitioners are usually left alone by the press, it would seem that as soon as a patient is admitted to a public hospital he is assumed to be public property as far as his news value is concerned. If he is a man of some importance, journalists may inquire about his progress early and often so that an obituary of him can be printed promptly if he dies. This is distressing to both patient and physician. Dr. Erik Husmark suggested that the newspapers put the reporting of medical news on the same footing as that enjoyed by music, literature, and the theater. While these subjects are dealt with in the big papers only by well-qualified reporters, medical matters are often reported by the uninitiated. The journalists and editors for their part referred more than once to the mutual jealousy of physicians and to the suspicion that if one of them appears in the papers his colleagues will suspect him of advertising himself. While a busy surgeon cannot be expected to tell the press on the phone how his patient fares, it would be appreciated if he would let the press know whether the patient is alive or dead and whether he has a serious condition. One speaker referred to setting up a central pool from which all papers could draw their medical news as an impractical plan because reporters by nature fight shy of a pool from which all can draw. Most editors prefer their own sources of information.

Prednisone for Asthma.—From a hospital in Gothenburg comes a report from Dr. Hans Arnoldsson on his experiences with prednisone and prednisolone in the treatment of bronchial asthma. All his 100 patients were severely affected and had failed to recover under conventional treatment, and 56 of them showed radiologically demonstrable signs of emphysema. The dosage was usually 30 mg. daily during the first few days, after which it was gradually reduced to a maintenance dose of 5 mg., which was in most cases sufficient to keep the asthma under control. There were, however, a few patients who needed as much as 10 mg. daily. In 71 patients complete freedom from symptoms was achieved and in 19 appreciable amelioration. No definite clinical improvement could be claimed in the remaining 10. In two patients, however, radiologically demonstrable gastric ulcer developed a month or two after this treatment had been started. Arnoldsson finds that hypertonia and cardiac insufficiency need not be contraindications for treatment with prednisone and that it does not require precautionary measures in respect of sodium and potassium regulation; however, diabetes is a contraindication, and the risk of gastric ulcer must be borne in mind.

Cottage Hospitals.—In *Svenska Lakartidningen* for Sept. 28, Dr Gunnar Redell discussed the influence of modern advances in surgery on the functions of small hospitals classified generically as "cottage hospitals." When surgery was still a comparatively simple matter, an enterprising surgeon might have been justified in performing a laparotomy in a small hospital in a thinly populated area, but to get away from the anachronism of performing major operations in small hospitals today, the functions of each of the smaller hospitals need scrutiny and perhaps revision. A recent memorandum by the Swedish Ministry of Health warns against the building of small hospitals without reference to their special functions. The larger cottage hospitals may be expanded so as to become important surgical hospitals, while others may care for the chronically rather than the acutely ill patient. They should have some observation beds and others for after-care of maternity patients. In industrial areas they may also serve as clearing stations.

UNITED KINGDOM

Mode of Transmission of Micrococcus.—Experiments carried out by Hare and Thomas on nasal carriers of Micrococcus pyogenes var. aureus suggest that this organism is not transported primarily by the expulsion into free air of droplets or droplet nuclei coming from the anterior nares (*Brit. M. J.* 2:840, 1956). Although the nasal carrier is the ultimate source of micrococcic infections, the organism is spread by transfer, in three stages, from the nasal secretions. The first stage is the transfer of the micrococci by hands or by handkerchief or any other object coming into contact with the nose to the skin, clothing, bedding, and other objects in the vicinity of the carrier. The next step is the release of the organism into the air. This may result from friction and the dislodging of dried particles from the skin and hair, from the spattering of water droplets when washing, and from the shaking of clothing on which the organisms have settled. Many members of hospital staffs are carriers of micrococci and dissemination in the afore-mentioned ways may occur anywhere in the hospital. The third step is the transport of infected particles by air currents to other persons in the vicinity. In this manner the micrococci may spread to the anterior nares of other persons and produce the carrier state in them. Highly susceptible tissues, such as the conjunctiva of the newborn child and the fresh open wounds occurring in operating theaters, may become infected. Breathing, coughing, talking, and sneezing expel only comparatively few organisms. Some carriers produce a much greater degree of air contamination from the friction and movement of their clothes than do others. In a hospital, such carriers are probably more dangerous as sources of infection than are persons with micrococcic infections of the skin. If they wear a sterile gown over their ordinary underclothes, they may still cause potentially dangerous degrees of air contamination. Even when wearing a complete set of sterile operating clothes, they may still disseminate micrococci into the surrounding air.

Micrococcic Pneumonia.—According to Hausmann and Karlish, micrococcic pneumonia is becoming more prevalent (*Brit. M. J.* 2:845, 1956). They reported 18 cases of this condition in a series of 122 consecutive patients with pneumonia admitted to a medical unit. The outstanding features in the patients were the severity of the clinical course of the disease and the number of suppurative complications. Only 6 of the 18 patients responded to treatment with penicillin. This observation is in keeping with the general experience that micrococci are becoming increasingly resistant to penicillin. A history of previous pulmonary disease, such as chronic bronchitis, asthma, or recurrent pneumonia, was obtained in over 40% of the patients. The patients in whom penicillin was no longer effective responded to tetracycline and erythromycin.

Pellagra Caused by Isoniazid.—Harrison and Feiwell (*Brit. M. J.* 2:852, 1956) record a case of pellagra developing in a woman given isoniazid for the treatment of multiple sclerosis. She was given 300 mg. of isoniazid daily and 20 mg. of pyridoxine three times a day. The summer was exceptionally warm and sunny, and, after two or three months, she began to complain of burning sensations in the hands and feet. Eventually a typical symmetrical red-brown pellagral dermatitis developed on the hands and feet. At night she was unable to sleep with her limbs covered. Angular stomatitis, another pellagral lesion, was also present. Therapy with isoniazid was stopped, and the patient was given 1 gm. of nicotinamide. Within 18 days the burning pain left and the skin lesions cleared. Although the patient's diet was suspected of being inadequate, it should have been sufficient for normal needs. Therefore, the pellagra was attributed to the isoniazid having produced a nicotinic acid deficiency by a competitive block in one of the enzyme systems utilizing nicotinic acid.

Medical Manpower in Scotland.—The Scottish Committee of the British Medical Association has submitted a memorandum to the Minister of Health on medical manpower in Scotland. The committee said that it could only speak of present trends and could not predict those of the future. There are four Scottish universities, and so far they have trained more physicians than are needed to satisfy the requirements of Scotland. Many of these physicians go to England and elsewhere. For many years the proportion of men and women in Scotland wishing to become physicians has been higher than in the rest of the British Isles. In 1948-1949 there were 2,419 Scottish general practitioners within the National Health Service, 653 specialists, 274 prospective specialists, and 427 junior hospital medical staff. By 1955 these figures had increased to 2,568, 876, 353, and 517 respectively. These physicians serve a population of about 6 million. By far the greatest increase—about 30%—has been in the number of physicians serving in hospitals under the health service. This increase was inevitable, since the amount of service rendered by the hospitals has been increased by 35 to 40%; thus there is no question of overstaffing the hospitals. The committee thinks that the size of the hospital staffs should remain stationary unless there are new developments in medical knowledge and practice. The increase in hospital attendance has not led to any reduction in the general practitioner service. Patients are seeing their physicians oftener, and the numbers referred to hospital must, therefore, inevitably increase. The number of general practitioners in Scotland is probably insufficient, as most family physicians have patient lists that are still too high for efficient service.

The committee estimates that British medical schools will have to produce enough replacements for the total medical force of about 60,000 and enough more to allow for an increase of 10% in the next 10 to 25 years. Admissions of students to Scottish medical schools have fallen by 20%. This is attributed not only to a decline in the number of entrants to the professions but also to more rigorous selection of students. Formerly most students came from professional, including medical, families, but this is no longer so. Physicians are not encouraging their children to enter the medical profession. Many of the professional classes, whose income has not increased to the same extent as that of the working classes, cannot afford to put their children through medical school. The committee thinks, however, that any decline in the number of entrants is only temporary. The factors likely to influence medical requirements are those immediately and directly affecting the practice of medicine and the general level of health in the community. In the first group are advances in the knowledge and understanding of disease processes and in the means of treating or preventing them. The committee deprecates the existence of a system whereby the organization and financing of a medical service depends on an annual parliamentary vote. The money that is forthcoming is usually unconnected with medical needs and has to be determined in advance. This does not make for flexibility and is likely to affect the hospital and specialist services the most.

The committee is not convinced that the increasing age of the population will result in an increased need for medical services. Much of the illness of older persons is preventable, so that, in the future, geriatric services should reduce rather than increase the demand for medical services in older persons. Studies on school children show an improvement in the general level of health in the young. This has been largely due to preventive medicine, and it may be that more physicians will be needed in this branch in the future. More will also be needed for the treatment, and possibly prevention, of psychogenic disorders. It is estimated that the annual number of physicians required for replacement in Great Britain is about 2,200. The figure for 1955 was 2,309. An intake into medical schools of this number does not allow a large margin of physicians to meet the increased demand that the committee thinks will arise in the near future. To produce annually a sufficient number of physicians for that would require an intake of nearly 3,000, this allows for a student failure rate of about 15%. This number is in excess of the present total intake of all medical schools in the British Isles. There is thus no evidence at present that steps should be taken to limit the number of entrants into the medical profession. Long-term requirements cannot be forecast. The situation should be kept under review. If there is any excess number of entrants over demand, the entrance and qualification standards could then be raised.

WORLD HEALTH ORGANIZATION

Disposal of Radioactive Wastes.—A. W. Kenny in the *Bulletin of the World Health Organization* (14:1007, 1956) states that, although the immediate burning of the skin by relatively intense sources of radioactivity has long been appreciated, the fact that smaller sources, producing no immediate visible effect, may cause harm and even death was recognized slowly because the effects did not develop until years after the irradiation and were similar to those of known diseases. In consequence, the pioneer workers developed blood diseases and suffered skin injuries. Even in recent years there have been injuries to the eyes of scientists working with high-energy radiation machines. The fact that no cure or treatment of these diseases is known must make for caution in estimating maximum permissible levels. At the present stage of development of the atomic power industry and of the use of radioisotopes, no particular difficulty is met in achieving these levels by means of conventional methods of waste disposal, except with the high-level liquid wastes, consisting largely of fission products from the chemical processing of irradiated fuel elements, and with contaminated, noncombustible, solid wastes. These wastes must be stored. Fortunately, since the liquid wastes are of small volume, storage is not expensive, but the possibility of leakage to ground waters must give rise to some apprehension when atomic power is widely used. For this reason, methods of fixing the fission products in solid form, e. g., by absorption in clay or by incorporation in cements or ceramics, have been investigated. Alternatively, it seems that a process based on chemical precipitation of the two long-lived fission products, radiostrontium and radiocaesium, might succeed, for the remaining fission products, after storage for 10 to 15 years, would decay to levels that would permit disposal without difficulty.

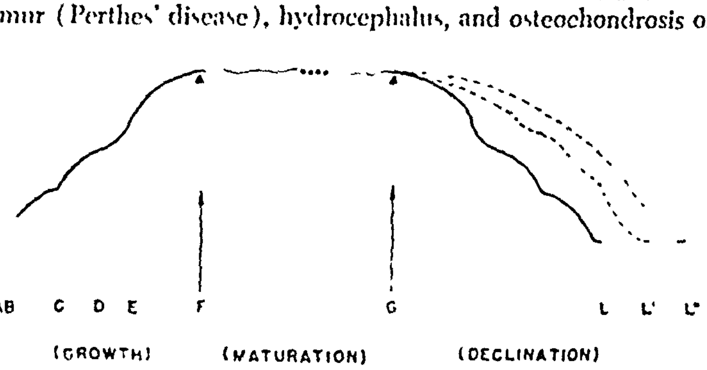
CORRESPONDENCE

GERIATRIC RESEARCH

To the Editor:—The term geriatric research must be better defined or dropped entirely. At present it includes research done in anatomic or pathological categories (myocardial infarction, atherosclerosis, cancer) solely on an age basis. There is rationale for this, since each of the categories included is accentuated in the later years of life in severity and prevalence. However, none of the categories is limited to this period of life and so should not be included comprehensively in geriatric research.

In pediatric research *it* may be possible to find the counterparts of geriatric research. Growth and development clearly belong here. On the gerontologic side of the picture, normal alterations *of function that begin at the close of the mature phase*, that are *attributable only to age*, and *that* are strictly retrogressive (loss of physical agility and muscle tone, bone hardness) would be comparable.

In childhood, liver, spleen, kidney, lungs, bones, blood, and all other body components have abnormalities of action that are limited strictly by puberty *or earlier maturations*: hyaline membrane disease, to the first few days of life; nephrosis, *to the period from 2 to 5 years of age. Osteochondrosis of capital epiphysis of femur* (Perthes' disease), hydrocephalus, and osteochondrosis of navicular (Köhler's bone disease) also appear in normal children within very circumscribed age limits. Susceptibility to infection varies sharply, and the sequelae vary greatly and are as bound by the changes with age. Infants are highly susceptible to streptococcic infection, but the occurrence of rheumatic fever is rare in children under 5 years of age; newborn infants are immune to measles, mumps, and typhoid, but by 6 months of age they have become susceptible to the first and by 2 years of age to the second. It would seem logical that each of these examples, and all the others not given, might be matched at the other end of life. If life were graphed it might be done as illustrated in the figure, taking only the more conspicuous nodes for the purpose.



Graph depicting phases of life

The components A through F represent the growth phase. A-B *represents* the rapid development from the ovum to birth; B-C, from birth to 5 years of age; C-D; 5 to 9 years of age; D-E, 9 years of age to puberty. and E-F. puberty to somewhat more years. possibly to 25. F-G, representing the phase of maturity, although obviously not a flat horizontal line, begins—and ends—vaguely, at different ages in different people. It does not begin sharply at sexual puberty, but later, when height ceases to increase and the forming mind stops indiscriminate absorption and becomes stabilized. It is not ended by a sexual change (menopause) any more than it is begun by one. During the maturation phase the course is up, mentally, and down, physically. The two courses are not widely separated but have this definite digression in their directions.

The ill-defined G *point is a critical one* in preventive geriatrics. It is here that the mature blood vessel begins to lose its vigorous tone and to become too rigid or too impermeable, or both. The nerves, muscles, and all other parts suffer as a result.

G has even a greater variability *in the time of* its appearance than F. It is as if life increases, and then diminishes, in harmonics. The latitude in gestational periods is not great, but perhaps is 10% of the life span to the time of birth. Puberty varies from 9 to 15 years of age in its appearance. This is roughly a 40% difference between normal individuals. The G point varies normally among individuals much more widely than this, and, in the exaggerated instance of the comparison of the times of its appearance in a progeric child 6 years of age to that in a normal adult of 70, it is *several* hundred per cent. Commonly, it is observed that the onset *and rate of aging is one of the most variable* physiological phenomena among mankind. The F-G span has diseases of its own, arterial spasm (notably of the coronaries but also *of* the extremities), thromboses, embolisms, peptic ulcers, and alcoholism are some of these. They may precipitate aging, *they may bring the* G point earlier, but, of themselves, they are not geriatric problems.

Geriatric research should be directed toward the study of phenomena that might be discovered to be as compartmentalized as those known to exist in the pediatric age group. Its objective should be the recognition of the G point, and the postponement of it, by reversing its earliest phases through nutritional, physical, or other simple measures. *Once past it, however, the declination* of the curve G-H-L should be established, its wide variability acknowledged, and the concomitants of its slopes and horizontals learned so that each can be approached separately as well as with the presently conceived, *all inclusive, frontal attack.*

PERIODIC EXAMINATIONS FOR PHYSICIANS

To the Editor:—Like many other speakers of the American Cancer Society addressing the lay public, I have often endorsed the recommendation of yearly routine health examinations. At times a rather obvious question is asked: "Do doctors and their wives follow this advice?" Many surveys have pointed to early detection as the key and best hope for cure of cancer at present, also *other diseases* have been detected and treated early. I am certain that, like myself, many of our colleagues would be glad to participate in setting aside certain hours for checking our fellow physicians and their wives. Doctors, doubling as patients, may *also help clarify* several unsettled questions of clinical laboratory and x-ray procedures. A special committee might do well to study these *questions* and to define procedures along with methods of compensation of the laboratory for actual expenses. Some physicians hesitate to impose *on* their colleagues by asking *for an* examination. This may or may not be justified, but it is hardly compatible with preservation of good health. Above all, *should* not the profession demonstrate to the public a model system of health checkups practiced on their own members?

MEDICAL FILM REVIEWS

Fractures of the Leg and Ankle: 16 mm., color, sound, showing time 29 minutes. Produced in 1956 by Churchill Wexler Productions, Los Angeles, for and procurable on loan from Veterans Administration, Central Office Film Library, Washington 25, D. C.

This film presents, in a simple and diagrammatic manner, the skeletal anatomy of the leg and ankle and a sensible and practical outline of the common types of fractures that occur in the shafts of the tibia and fibula and of the ankle malleoli. There is no presentation of a variety of methods of treatment for each fracture. The functional anatomy and the forces by which each fracture is caused are clearly demonstrated. In outlining the open reduction of the fracture of the tibial shaft, it would have been well to emphasize bone grafting, as an added insurance for healing, at the time the fracture was opened. With regard to the position recommended for the immobilization of an eversion ankle fracture, a demonstration of an inversion position of the heel and talus rather than one of a twist of the foot would have been proper. The photography, animation, and art work are outstanding. The film is excellent for a review of functional anatomy and therapy for injuries of the leg and ankle. It is recommended for showing to general practitioners, surgeons, and medical students.

Operative Obstetrics: 16 mm., color, sound, showing time 27 minutes. Prepared by John Q. Adams, M.D., and Ben E. Everett, M.D., University of Tennessee, Memphis. Produced in 1955 by and procurable on loan from Sandoz Pharmaceuticals, Route 10, Hanover, N. J.

This film demonstrates various maneuvers of the forceps commonly used in the practice of obstetrics. The proper application of the Simpson-De Lee forceps is demonstrated, both on an excellent manikin and on live patients in three different types of deliveries: occiput anterior and occiput posterior rotation and breech. The normal third stage is shown as well as the episiotomy repair. The continuity of the film is excellent; however, it would be well to show the placenta as it is inspected and also to show the checking of the fetal heart tones on all three patients instead of only on the last. The photography is fair. The film would be ideal teaching material for medical students, interns, residents, general practitioners, and nurses. However, it is not recommended for specialists.

Home Care: An Approach to the Treatment of Chronic Disease: 16 mm., black and white, sound, showing time 26 minutes. Presented by the Benjamin Rosenthal Foundation, Inc., with the technical assistance of Montefiore Hospital, New York. Produced in 1955 by Information Productions, Inc., New York. Procurable on rental ($10) or purchase ($50) from Health and Welfare Materials Center, 10 E. 44th St., New York 17.

This film presents an effective method of bringing hospital-type care into a patient's home, with the full complement of medical, nursing, and social service. The film shows the effects of such care on patients with cancer, heart disease, asthma, arthritis, and other chronic conditions; it also describes the factors that go into the selection of patients for treatment in a home care program. The roles of the physician, nurse, and social worker are also shown. The results of this type of care on a patient's physical and emotional well-being are described. The film gives a good demonstration of the effective use of home facilities for care and rehabilitation of the chronically ill; however, it is important to emphasize that the teaching facilities were available to the group shown in the film. A discussion guide accompanies the film. It will be of interest to physicians, nurses, social workers, and also to the parents of chronically ill patients.

Excision and Split Skin Grafting of Extensive Pigmented Nevus of Right Upper Extremity: 16 mm., color, sound, showing time 18 minutes. Prepared by Thomas D. Cronin, M.D., and Raymond G. Brauer, M.D., Houston, Texas. Produced in 1955 for and procurable on loan from Eaton Laboratories, Norwich, N. Y.

This film shows an 11-year-old girl who has an extensive pigmented hairy circumferential nevus involving a major portion of the right arm and forearm. She also has other smaller pigmented nevi and an associated scoliosis. The film demonstrates how the large tumor is removed and then covered with a large split thickness skin graft. As fat offers a poor bed for a skin graft, the skin grafting is delayed one week to permit a fine granulating bed to form over the fat. The technique of adjusting and using the Padgett dermatome is shown. The postoperative course is followed, showing the use of a foam rubber pressure bandage to minimize hypertrophy of scar around the grafts. Surgically speaking, the film is well produced and the photography is good. It would be of particular interest to general practitioners and dermatologists in pointing out what can be done with this type of lesion.

NEW FILMS ADDED TO A. M. A. MOTION PICTURE LIBRARY

You Are There: The Tragic Hour of Dr. Semmelweiss: 16 mm., black and white, sound, showing time 25 minutes. Produced in 1955 for CBS Television. Procurable on rental or purchase ($125) from Young America Films, 18 E. 41st St., New York 17 or on loan (service charge $2) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 10.

This film, which portrays a significant highlight in man's fight against superstition and ignorance, is one of the series in which the well-known television personality, Walter Cronkhite, brings history to life in a way that makes the viewer feel that "You Are There." In a setting that realistically portrays the dingy, frightening atmosphere of hospitals a century ago, Dr. Semmelweiss is dismissed from his Vienna hospital because of his fight to prevent childbed fever, which, he believes, is due to inattention of the medical profession to sanitary conditions. To see this film is a memorable experience because of its gripping drama, which is, perhaps, most keenly felt by anyone with medical experience but will be appreciated by any mature audience. It is easy to identify one's self with this young doctor who finds himself unable either to become resigned to the abuses he sees or to discover a way to correct them. He sees a young mother brought to a maternity hospital in old Vienna and assigned to a ward where the death rate from puerperal fever is known to be high. She is browbeaten into submission, and the expected tragedy happens—a healthy young mother is lost, and a child is orphaned. So plausible is the action that the ultimate defeat of Dr. Semmelweiss at the hand of well-entrenched politicians, his frustration, and his insanity enlist one's sympathy. This is one of the best films available today as a means of impressing people with the progress that has been made in medicine and in hospital operation. It can be especially recommended for medical students and student nurses.

Embryology of the Ear: 16 mm., color, sound. Presented by the American Academy of Ophthalmology and Otolaryngology with the cooperation of George W. Bartelmez, Ph. D., Carnegie Institute of Washington, D. C., and Franz Altman, M.D., Columbia University, New York. Produced in 1955 by Sturgis Grant Productions, New York. Procurable on loan (service charge $5—each part) from Motion Picture Library, American Medical Association, 535 N. Dearborn St., Chicago 11.

Part I: The Inner Ear: Showing time 30 minutes.

This film demonstrates that the ear can be divided into three parts: external, middle, and inner. The demonstration continues with the inner ear, showing the otic labyrinth, the otic capsule, and the periotic labyrinth.

Part II: The Middle Ear: Showing time 27 minutes.

This film deals with the middle ear and the external ear.

Part III: Blood Vessels—Arteries: Showing time 33 minutes.

The final portion of the film discusses the blood vessels, arteries, and veins, and it ends with a summary of the entire subject. This motion picture represents much detailed observation on the development of the various parts of the ear throughout the various stages. In the film this detailed information has been brought together and presented in a way in which the development can be clearly followed. The amount of material contained here is so great that for the purposes of study the film has limited value. It is to be regarded more as an authentic and detailed record of the various stages of development, a record that can be consulted to best advantage by the student already familiar with most phases of embryology. It is not suitable for showing to medical students, but it should be of great value as an authoritative source of information to those trained in otology or embryology.

MEDICAL LITERATURE ABSTRACTS

INTERNAL MEDICINE

Why Drugs Are Not Enough in the Treatment of Tuberculosis. A. R. Allen. A. M. A. Arch. Int. Med. 98:463-466 (Oct.) 1956 [Chicago].

One hundred seventy-one patients with caseous and/or cavitary pulmonary tuberculosis were subjected to a regimen consisting of the administration of streptomycin, aminosalicylic acid, and isoniazid given concurrently and continuously from admission to discharge, with early resectional surgery when indicated. The results of the gastric culture before resection and the culture of a portion of the resected specimens were compared with the results of bronchoscopy and pathology in 168 patients.

Conversion occurred in 84% of the patients by the end of four months of combined chemotherapy with all three drugs, a better conversion rate than can be obtained with only streptomycin and aminosalicylic acid. However, of the 145 patients who were negative on culture before surgery, 12% had positive cultures of their specimens, another 11% had positive smears of their specimens, and 11% had reactivation of their lesions. Thus drug therapy in any combination will not cause conversion in all patients. The types of lesions that are not sterilized by chemotherapy are thick-walled cavities, caseous masses over 2 cm. in diameter, and bronchial stenosis and bronchiectasis. Caseous lesions with a bronchial connection manifested by positive cultures before drug therapy is started are as dangerous as open cavities. Apparently, combined chemotherapy is less effective in extrapulmonary tuberculosis than it is in pulmonary disease. Using equipment and techniques available only in a tuberculosis hospital, i.e., good culture methods, anteroposterior tomographs, and bronchoscopy with right-angle and foroblique telescopes, it is possible to determine which patients will require more than combined chemotherapy alone. If resectional surgery is indicated, it should be performed within three to four months after starting combined chemotherapy. The acid-fast rods found in pathological specimens are viable, virulent tubercle bacilli and if not removed surgically will result in reactivation. Drug therapy is merely a tool in the treatment of tuberculosis, effective for a limited time, and if it is not properly used the patient will have lost the opportunity for successful resection.

The Risk of Tuberculosis in Adrenal Cortex Therapy. J. Charpin and J. Béranger. *Presse méd.* 64:1507-1508 (Sept. 19) 1956 (In French) [Paris, France].

Five cases are described in detail to exemplify the appearance or recurrence of tuberculosis in patients who received cortisone as medication for other conditions. The infection was pulmonary in all cases, but in one it assumed a miliary form, involved the brain, and terminated fatally within two months despite the use of antibiotics. Statistical proof of a relation between the cortisone and the tuberculosis would be difficult because it would necessitate consideration of the relative frequencies of tuberculosis in those receiving and those not receiving cortisone. It is the opinion of the authors that tuberculosis after cortisone is in reality extremely rare; what is striking is the chronological relation and severity of the tuberculosis. They conclude that during cortisone therapy the risk of tuberculosis is practically negligible but that the lungs require watchful care none the less.

Lupus Vulgaris and Fatalities After BCG Vaccination. F. van Deinse. Ztschr. Tuberk. 109:33-40 (Sept.) 1956 (In German) [Leipzig, Germany].

Vaccination ulcers and suppuration of lymph nodes occur after BCG vaccination, but they are a part of the BCG primary complex—a severe form of this complex. Eczematoscrofulous or lichenoid cutaneous lesions also occasionally develop after BCG vaccination. This report is concerned chiefly with the development of lupus vulgaris (tuberculosis luposa) and with fatalities To date, 14 cases of tuberculosis luposa have been reported, 7 in the Scandinavian countries, 5 in Holland, one in Germany, and one in France. In four of these patients cure had not been established at the time the report was made. In view of the millions of BCG inoculations, tuberculosis luposa is an extremely rare complication, and whenever it occurred numerous other children and adults had tolerated the same batch of vaccine without any complications. It seems that an extremely rare individual hypersensitivity is responsible for the tuberculosis luposa reaction

Four fatalities attributable to BCG have been reported from the Scandinavian countries. There was a report from France concerning an infant vaccinated with BCG scarifications, in whom death resulted three months later from suppurating lymph nodes, high fever, and emaciation. No tubercle bacilli could be demonstrated in this infant, and isoniazid therapy was ineffective The author does not believe that this fatality should be ascribed to BCG, although the French authors who reported the case did attribute it to the vaccine. The bacteriological findings in the four deaths reported from the Scandinavian countries seem to indicate that the BCG vaccine was the cause, but the author shows that the cases took a very unusual clinical course, and histological studies revealed no changes indicative of tuberculosis. Thus, although the first impression was that BCG had caused these deaths, closer investigations show that this has not been definitely proved. BCG is highly susceptible to antibiotics, and yet none of these four patients had shown the slightest response, although the cultured organisms had remained sensitive. The author questions the possibility that the diagnosis of tuberculosis can be based on bacteriological findings alone, and suggests that a still unknown, related organism may have been present. Even if the deaths were really attributable to BCG, the number of fatalities is so small, in view of the fact that over 100 million persons throughout the world have been vaccinated with BCG, that BCG vaccination is still the safest method of protective vaccination.

Rheumatoid Arthritis and the Positive L. E.-Cell Phenomenon J. H. Kievits, J. Goslings, H. R. E. Schuit and W. Hijmans Ann Rheumat. Dis. 15:211-216 (Sept.) 1956 [London].

Joint symptoms occur in a large number of patients with lupus erythematosus. If Hargrave's L. E.-cell test could be considered absolutely specific, it would then seem possible to diagnose some cases of rheumatoid arthritis as monosymptomatic or oligosymptomatic forms of systemic lupus erythematosus. To investigate this possibility two series of adult patients with rheumatoid arthritis were studied, and the test was also applied to several control series. The first of the two series consisted of 388 patients with rheumatoid arthritis. In order to exclude the unintentional selection of possible cases of lupus erythematosus, the second series comprised 100 unselected consecutive cases of rehumatoid arthritis as they were admitted to the department of rheumatology, University Hospital, Leyden, Netherlands. L. E. cells were found in 17% of the 488 patients with rheumatoid arthritis. This observation led to a statistical analysis of its clinical implications The group with the L. E.-cell phenomenon showed a higher frequency of splenomegaly, diseases of the lower respiratory tract, abnormal urinary sediment, anemia, false-positive tests for syphilis, and a high erythrocyte sedimentation rate that failed to fall after a first course of gold treatment. In individual patients with rheumatoid arthritis the positive L. E.-cell phenomenon was not related to a typical clinical picture.

The place of publication of the periodicals appears in brackets preceding each abstract.

Periodicals on file in the Library of the American Medical Association may be borrowed by members of the Association or its student organization and by individuals in continental United States or Canada who subscribe to its scientific periodicals. Requests for periodicals should be addressed "Library, American Medical Association." Periodical files cover 1947 to date only, and no photoduplication services are available. No charge is made to members, but the fee for others is 15 cents in stamps for each item. Only three periodicals may be borrowed at one time, and they must not be kept longer than five days. Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Familial Primary Systemic Amyloidosis: An Experimental Genetic and Clinical Study. J. G. Rukavina, W. D. Block and A. C. Curtis. J. Invest. Dermat. 27:111-131 (Sept.) 1956 [Baltimore].

The authors had an opportunity to study familial primary systemic amyloidosis when two cousins were referred to their hospital for the study of an unusual syndrome consisting essentially of neurological and ophthalmologic symptoms. Data obtained from these patients suggested a reservoir of clinically similar cases in a genetically isolated community. Sixty-six members of this pedigree agreed to be investigated for the presence or absence of clinical or subclinical inherited primary systemic amyloidosis by means of clinical, laboratory, and experimental biochemical methods. Approximately one-half of the 66 members of this family have been shown by clinical, laboratory, and experimental methods to be afflicted with clinical or subclinical primary systemic amyloidosis. In one patient clinical suspicion was confirmed at autopsy. In three others a positive tissue biopsy (skin and ovarian tissue) for amyloid deposition reenforced the presumptive diagnosis. Evidence secured by this study points to a dominant form of inheritance. More significantly it emphasizes the importance of the electrophoretic serum and lipoprotein relationship to the pathological process. The clinical signs and symptoms of familial amyloidosis described confirm the observations of previous investigators. In this family group, at least, the broad clinical spectrum represents a predictable, concatenated series of events culminating in order of descending frequency in peripheral neuropathy, skin changes, hepatic enlargement and dysfunction, cardiovascular insufficiency, eye changes, gastrointestinal symptoms, and splenomegaly. The occurrence of the carpal tunnel syndrome represents a previously unreported finding in the inherited form of the disease. In no case was there clinical evidence of macroglossia, bleeding tendency, or papulonodular dermatological manifestation of the disease.

The usual laboratory procedures were inadequate in the diagnosis of this process, but free electrophoresis of the serum of these patients revealed an atypical peak migrating between the beta and alpha-2 globulin areas, and ultracentrifugation demonstrated elevation of the serum lipoproteins. These methods should be used if primary systemic amyloidosis is to be recognized. The demonstration by ultracentrifugation of abnormally elevated lipoproteins, particularly in the -S 25-40 and 20-25 fractions, suggests that at least in part familial primary systemic amyloidosis represents an inherited aberration in lipoprotein metabolism.

Observations on Hepatic and Renal Dysfunction in Trichinosis: Anatomic Changes in These Organs Occurring in Cases of Trichinosis. J. M. Guattery, J. Milne and R. K. House. Am. J. Med. 21:567-582 (Oct.) 1956 [New York].

Functional and pathological derangements in the liver and kidney were observed in three men between the ages of 40 and 45 years and two women aged 18 and 23 years with trichinosis. Liver function tests were performed in the three men. Hepatic dysfunction was manifested by a reduction of bromsulfalein excretion in all; an abnormal result from this test was obtained 16 days after the onset of the initial symptoms in one of these patients. The men survived, but the two women died and autopsy was performed in both. Findings suggested that the hepatic changes may include direct invasion of the liver sinusoids by the Trichinella larvae; fatty changes and degeneration, particularly involving the peripheral zone of the liver lobule early in the course of the disease; and progression to frank cirrhosis.

Hypoalbuminemia was a prominent feature in four of the five patients. Maintaining the general nutrition of the patients was a major problem. All had pronounced anorexia; nausea, vomiting, and diarrhea were protracted in two. Malabsorption from the gastrointestinal tract may have been a factor. Nephritis occurred in three patients. Abnormal urinary findings consisted of albuminuria, hematuria, and granular and hyaline casts. Both glomerular and tubular damage was revealed by autopsy. Trichinosis may simulate acute and chronic glomerulonephritis.

Trichinosis in its severe form is a diffuse disease involving widespread vascular damage, widespread tissue invasion, and multiple organ damage. There is no specific therapy for trichinosis. A rigid program of care is important; this includes maintenance of adequate nutrition, alertness to possible intercurrent infections and to the possible diffuse nature of the disease, and provision of proper follow-up. Two of the severely ill patients received acetylsalicylic acid (aspirin) on a four-hour schedule with apparently satisfactory response. The use of salicylates will bear further investigation.

Diabetes Mellitus and Addison's Disease in Same Patient. V. Faber and P. Grønbaek. Ugesk. læger 118:985-988 (Aug. 23) 1956 (In Danish) [Copenhagen, Denmark].

To date 56 cases of simultaneous diabetes mellitus and Addison's disease have been reported. The combination occurred in all age groups, equally in men and women, with average duration of life of five years. In 38 cases diabetes mellitus developed on an average of eight years before the Addison's disease, in 13 cases Addison's disease preceded the diabetes by from one-half to five years, and in five cases the two diseases were diagnosed simultaneously. Because of the antagonistic action of the pancreas and the adrenal cortex on the carbohydrate metabolism, the combination of the two diseases presents diagnostic and therapeutic problems. While a falling insulin requirement in a diabetic patient should always suggest complicating Addison's disease, diabetes mellitus in an Addisonian patient will often be latent. With simultaneous onset of the two diseases, differential diagnosis of diabetic coma from an Addisonian crisis presents special difficulties. In the uncomplicated combination it is rational to treat the adrenal insufficiency first. Then, when the adrenal insufficiency is fully compensated, the diabetes is treated like an uncomplicated diabetes. In the case described, in a woman aged 29, the high blood sugar values and ketonuria testified for diabetic coma, but there was no Küssmaul respiration. Slightly lowered blood pressure and absence of diarrhea testified against Addison's disease, but the patient's marked insulin sensitivity pointed to adrenal insufficiency. The patient has been treated with desoxycorticosterone acetate, salt, diet, and insulin, and her condition has been satisfactory for a year and a half. She has not been given cortisone, as her diabetes was considerably aggravated following a cortisone test, with development of diabetic precoma. Cortisone treatment in the presence of both diseases seems to be rational only in the case of frequent and distressing hypoglycemic attacks.

Renal Vein Thrombosis and the Nephrotic Syndrome. V. E. Pollak, R. M. Kark, C. L. Pirani and others. Am. J. Med. 21:496-520 (Oct.) 1956 [New York].

Thrombosis of the renal vein with the nephrotic syndrome was observed in two men aged 29 and 35 years. The younger man died of massive gastrointestinal hemorrhage. The case of the patient who survived is described. He had multiple pulmonary infarctions and thrombosis of both common iliac veins. The nephrotic syndrome developed after gradual or incomplete occlusion of the left renal vein. Two months later more rapid occlusion of the right renal vein occurred. The right kidney became functionless and secondarily infected, and was removed. Treatment with anticoagulants and antibiotics reversed the previously relentless downhill course, and the patient thereafter made an uninterrupted recovery.

Fourteen cases of the clinical syndrome of thrombosis of the renal vein associated with the nephrotic syndrome in 9 male and 5 female patients between the ages of 12 and 72 years were collected from the literature. The clinical features varied with the rapidity of the onset and completeness of occlusion of the renal veins. Adults with thrombosis of the renal vein may have definite symptoms referable to the affected kidney, such as sudden onset of hematuria, lumbar pain and tenderness, and enlargement of the kidney. Often there is evidence of thromboembolism in the lungs, pelvis, extremities, and elsewhere. In others, all these symptoms may be of a milder degree or absent and the nephrotic syndrome of obscure origin may be the only clinical manifestation of the thrombosis of the renal vein. In between are patients with a combination of the nephrotic syndrome and evidence of thromboembolism.

Histological observations made on sections from serial percutaneous renal biopsies in the two patients and autopsy findings in these two patients and in five of those reported by other workers revealed that the glomerular basement membrane was thickened and the tubules were atrophied. The interstitial tissue was edematous at first and later became the seat of an extensive fibrosis. The changes in the tubules and interstices were out of proportion to those in the glomeruli.

SURGERY

Percutaneous Left Ventricular Puncture in the Assessment of Aortic Stenosis. R. Brock, B. B. Milstein and D. N. Ross. Thorax 11:163-171 (Sept.) 1956 [London, England].

Two questions have to be answered in assessing aortic valvular disease. The first is whether, in a patient with signs of pure aortic stenosis, symptoms such as angina or dyspnea are due to the aortic stenosis or to associated coronary or pulmonary disease. The second is whether aortic stenosis or regurgitation is dominant in a patient who has a mixed lesion. These questions cannot be answered by indirect methods of investigation. Measurement of the systolic pressure gradient across the aortic valve is a routine procedure at operation for aortic stenosis. The authors have now developed a method by which this information can be derived from preoperative left ventricular pressure measurements. They measure the gradient by direct puncture of the left ventricle through the intact chest wall and simultaneous brachial artery puncture. The procedure is simple and safe, causes no disturbance to the patient, and has given rise to no serious complications. It has now been performed 24 times.

The technique is simple, and in most cases the apex of the left ventricle seems to be almost subcutaneous. The ease with which the left ventricular pressure is obtained contrasts strongly with other less direct methods. Moreover, as a large needle can be used, a pure undamped tracing much superior to that obtained through a long fine catheter is recorded. This makes analysis of the record simple and more accurate. The authors never failed to enter the left ventricle in any case. In one patient who had cor pulmonale as well as aortic stenosis with a very large right ventricle extending electrocardiographically as far as V6, the needle inserted at the apex entered the right ventricle and a second puncture further back was necessary to enter the left ventricle. In 10 of these patients the needle was advanced as far as possible up the outflow tract and it was found that it could be advanced for a further 10 cm. after the ventricle was first entered before extrasystoles appeared on the electrocardiograph, suggesting that the needle had again penetrated the myocardium. Thus it seems that if the needle is passed along the line of the outflow tract it will remain in the ventricular cavity. The procedure is no more disturbing to the patient than the brachial artery puncture and far less so than puncture of the left atrium from the posterior chest wall.

Indications for Lobectomy in the Treatment of Carcinoma of the Lung. J. L. Robinson, J. C. Jones and B. W. Meyer. J. Thoracic Surg. 32:500-507 (Oct.) 1956 [St. Louis].

The 79 resections carried out by the authors for pulmonary carcinoma up to 1950 included only 3 lobectomies, but later, when as the result of a chest x-ray survey many patients with small, round, circumscribed, peripheral lesions came to surgery, they made wider use of lobectomies. Whereas before 1950 the proportion of lobectomies had been 3.8% of pulmonary resections, it jumped to 30.4% in 1950, and for the past two years the number of lobectomies has exceeded the number of pneumonectomies. Follow-up revealed that the three-year survival was 16.3% in 123 patients treated by pneumonectomy but 71.4% in 21 patients treated by lobectomy.

The authors made a survey among the surgeon members of the American Association for Thoracic Surgery to determine to what extent and under what conditions they are using lobectomy in treating patients with carcinoma of the lung. The results of that survey show that, of 318 surgeons replying, 91.8% use lobectomy in treating metastatic pulmonary carcinoma and 92.8% use lobectomy in treating primary pulmonary carcinoma. About 60% use it as an operation of choice in treating primary carcinoma of the lung; 40% use it only in patients whom they feel would not tolerate a pneumonectomy. Of the 318 surgeons who replied, 227 believe that they have sufficient experience with lobectomy to be able to offer an unqualified opinion regarding its efficacy. Seventy-six per cent (56.9% of the total replying) believe it offers as good a chance for long-term survival as does pneumonectomy, and only 24% (17.8% of the total) do not. On the basis of the replies to the questionnaires, as well as their own experience, the authors suggest the following points as a guide for lobectomy in pulmonary carcinoma. 1. It is the operation of choice in a peripheral lesion located well away from the fissures or adjacent lobes, with a satisfactory proximal length of uninvolved bronchus, and with no apparent extension to adjacent tissues or to the peribronchial, hilar, or mediastinal lymph nodes 2. It is a compromise operation in patients whose lesions do not satisfy the above conditions but whose cardiorespiratory or other clinical condition makes them unsatisfactory subjects for total pneumonectomy. 3. It is a palliative operation in patients who, at the time of operation, are found to have a lesion that obviously cannot be completely eradicated surgically but in whom such symptoms as hemoptysis, cough, or infection can be controlled better by lobectomy than by nonsurgical means.

Pneumonectomy for Pulmonary Tuberculosis: An Analysis of 151 Cases. V. O. Björk. J. Thoracic Surg. 32:528-547 (Oct.) 1956 [St. Louis].

Björk discusses the pathophysiological problems arising in the surgical treatment of 151 bad-risk patients undergoing pneumonectomy for pulmonary tuberculosis. Many patients undergoing this operation are in bad condition. They may have toxic conditions, having had fever, with considerable expectoration, for several months. The respiratory reserve is usually small owing either to disease of the only functioning lung or residues of a previous pneumothorax. One hundred eleven of the 151 patients have been followed for from one to five years or more, of the other 40 patients 16 are dead, 22 were observed for less than a year, and 2 could not be traced.

Pneumonectomy is reserved for destroyed lungs whether bronchial stenosis is present or not. A one-stage procedure with resection and osteoplastic wall thoracoplasty is recommended If the function of the remaining lung is impaired by disease or an old pneumothorax, the respiratory work for the patient in the postoperative period is often too great, with carbon dioxide retention as the result. Under these conditions prolonged artificial ventilation through a tracheostomy is indicated until the patient has regained strength enough to perform adequate ventilation and bring up the secretion. Of 111 patients followed one to five years after operation, 97, or 87%, are considered cured. Of the 11 patients with recurrence, 5 are well and working, with negative sputum but with a postive guinea pig test in the gastric washings

The Surgical Treatment of Pulmonary Tuberculosis in Childhood and Adolescence. D. W. Huish. Thorax 11:186-200 (Sept.) 1956 [London, England].

Huish reviews observations on 29 children under the age of 16 years who were subjected to major surgical procedures in the treatment of pulmonary tuberculosis. The children were resident in the eastern part of central Scotland, coming from both urban and rural areas. They derive from a population of some 500,000 people. Fifteen children were operated on for primary lesions, 14 for chronic "adult type" lesions. The 15 children with primary tuberculosis included 9 with segmented or lobar lesions, on whom 10 operations were performed, including 8 lobectomies There were two surgical, but no late, deaths. Lobectomies were performed also in two children in whom segmental or lobar lesions had caused bronchiectasis. Primary cavitation was established in only one patient, a 3-year-old girl, who obtained an excellent result from lobectomy. Thoracotomy with the intention of decorticating the left lung was carried out in a 12-year-old boy. The operation had to be abandoned, and medical treatment was resumed. Chronic fibroid lung resulted in 2 of the 15 patients with primary lesions. A whole lung was involved in both patients resulting in fibrous contraction of the lung with bronchiectasis One was cured by pneumonectomy. Decortication was attempted but had to be abandoned in the second patient with fibroid lung.

Of the 14 children who were operated on for chronic pulmonary tuberculosis, five had lesions that arose in close clinical relation to a primary infection and the other 9 showed the type of disease usually seen in young adults. The clinical course in all of them indicated a severe form of tuberculosis. Fourteen operations were performed: lobectomy in 7, extrapleural pneumolysis in 6, and open intrapleural pneumolysis in one. The one operative death in this group resulted from massive collapse of the other lung. The author concludes that surgery has a place in the treatment of primary pulmonary tuberculosis in childhood. Up to the present it has been employed mainly for the removal of irretrievably damaged lung tissue, but with the aid of more accurate pathological diagnosis there is a prospect of employing surgery to prevent such damage. The indications for surgical treatment of chronic pulmonary tuberculosis in children and adolescents are much the same as in adults, but collapse operations have little place, and in this age group resection is the method of choice.

Postgastrectomy Syndrome. H. K. Lassen. Ugesk. læger 118:1005-1012 (Aug. 30) 1956 (In Danish) [Copenhagen, Denmark].

From 1948 to 1953 subtotal gastrectomy for gastric or duodenal ulcer was carried out in 221 patients in Central Hospital in Randers. Follow-up of 163 of the 165 survivors (147 men, 16 women, aged mostly between 40 and 60) showed good results in 86, or 52.8%, satisfactory results with slight symptoms in 61, or 37.4%, and poor results in 16, or 9.8%. The dumping syndrome occurred in 36%, loss of weight was fairly frequent, anemia was seen in only 5 out of 137 patients, and active pulmonary tuberculosis had developed in two. There is no satisfactory explanation as to why certain persons have symptoms after resection for ulcer and others, fortunately the majority, have no special distress. The resection should not be too large, if it can be avoided, in order not to cause difficulty because of the small gastric stump, nor should it be too small because of the risk of occurrence of marginal or jejunal ulcer. Resection is the best treatment available for ulcer symptoms of longer duration. The dumping syndrome may be referable partly to purely mechanical causes, partly to an abnormal blood sugar curve with early hyperglycemia and late hypoglycemia, and partly to a shock-like condition with reduction in plasma volume. Possible loss of weight is due partly to the patient's asthenic type, partly to the presence of dumping or anorexia. The anemia, of a sideropenic kind, is due to reduced iron absorption. Other sequels are relatively rare.

Treatment of Diabetes Mellitus in Surgical Complications: Review and Suggestion. J. Pedersen. Ugesk. læger 118:971-979 (Aug. 23) 1956 (In Danish) [Copenhagen, Denmark].

A patient whose diabetes has been regulated for about three weeks with intensive diabetic preoperative treatment tolerates an ordinary operation without losing his regulation. The number of diabetic persons with surgical diseases is increasing and at the same time the relative frequency of these diseases is shifting, with diseases such as cancer increasing more than gangrene or infection. The decisive factor in treatment is the late diabetic complications, and most of the patients will have cardiovascular disorders. A number of patients have diabetes without glycosuria (high renal threshold). The author stresses the importance of preoperative prophylactic treatment aiming at a normal daily blood sugar level. A diabetic patient should not be treated operatively without the participation of an internist experienced in diabetes. The cooperation of surgeon, anesthesiologist, and internist should be routine. The importance of the personal factor is especially emphasized, i. e., that the treatment should be conducted by only a few persons and that in large hospitals with several surgical departments the treatment should be centralized.

Below-Knee Amputation in Arteriosclerotic Gangrene. R. R. Kendrick. Brit. J. Surg. 43:13-17 (July) 1956 [Bristol, England].

Kendrick has for several years employed below-the-knee amputations in preference to the above-the-knee amputations whenever possible. In a consecutive series of 59 amputations of the lower limb for obliterative arterial disease, 51 were performed through the calf, and of these 32 (63%) healed by first intention. Three patients died. Healing failed in two cases, and above-knee amputation was required. In addition, massive necrosis occurred in one stump, which had remained soundly healed for 18 months. Refrigeration anesthesia is of value in a few patients in whom the operative risk is very great. The formation of a hematoma is a serious complication in these amputations, and, unless the wound is completely dry, drainage is preferred.

Amputation below the knee permits better balance either with crutches or with a prosthesis; this difference in the elderly patient may mean that he is ambulatory. Walking is achieved following a below-knee amputation with greater facility and far less physical effort because of the longer and more efficient lever present. The below-knee stump is rarely associated with stump or phantom limb pains; also, of course, the desirable normal movements of the knee-joint are retained. The patient with a below-knee amputation has greater stability and freedom of movement when seated in a chair or even lying in bed, and it must be remembered that not infrequently both legs will eventually require amputation.

Acute Appendicitis in Infancy and Childhood: A Critical Review of Seven Years' Experience in a Children's Hospital. C. W. McLaughlin Jr. and C. Organ. Am. J. Surg. 92:558-561 (Oct.) 1956 [New York].

The authors analyze a consecutive series of 300 infants and children coming to surgery with the diagnosis of acute appendicitis. Twelve per cent of the patients in this series were admitted with perforated appendixes and 3.2% with appendiceal abscesses. The 300 children were operated on by the attending surgical staff of the Children's Memorial Hospital in Omaha. A McBurney incision was employed in 60%, a transverse incision in 17%, a right rectus incision in 15%, and a Davis or paramedian incision in 8%. The appendiceal stump was simply ligated in 87% and inverted after ligation in 13%. Closure with drains into the peritoneal cavity was used in 58% of the children with perforation but without definite abscess; in the other children with perforation and without abscess tight closure was used without serious complication. The 10 children with appendiceal abscesses had been ill an average of six and a half days on admission, and the conditions of some were extremely toxic. After suitable preparation with fluids, blood if indicated, and antibiotics, 8 of these 10 patients were operated on. In three of the eight only drainage of the appendiceal abscess was accomplished, with subsequent appendectomy three months later. In five of the eight primary appendectomy was carried out with drainage of the abscess. Two patients were handled conservatively with resolution of the abscess and the recommendation that appendectomy be performed subsequently. There were no deaths in the entire series of 300. Acute appendicitis in infancy and childhood, while still potentially a very serious disease, is rapidly becoming one of those that are well understood. Therapy is becoming standardized, and results are approaching the ideal.

NEUROLOGY & PSYCHIATRY

Benign Cysts of the Brain Simulating Brain Tumor. H. Handa and P. C. Bucy. J. Neurosurg. 13:489-499 (Sept.) 1956 [Springfield, Ill.].

The term "benign cyst of the brain" generally indicates either a porencephalic or an arachnoidal cyst. Any symptoms of cerebral involvement presented by patients with porencephalic cysts arise as the result of the cerebral defect and not because of the cyst, which is a purely passive and secondary development. The symptoms most commonly seen in such cases are hemiparesis and convulsions. Arachnoidal cysts may arise secondary to an infectious or inflammatory process in the leptomeninx, or they may be congenital or occur following severe cerebral trauma. If symptoms of cerebral involvement are present with such cysts, convulsions are the most common. The three patients whose histories are reported had brain cysts that did not fall into either of these categories, nor were they of neoplastic origin. These cysts lay within the brain substance and did not communicate either with the ventricular system or the subarachnoid space. Two of these cysts lay in the cerebral hemisphere and one was in the cerebellum. All three patients presented themselves with serious signs and symptoms of an intracranial space-occupying lesion with signs of increased intracranial pressure and of focal lesions of the brain. All three cysts were treated surgically. One was simply aspirated on several occasions. One of the others was opened into the lateral ventricle, while the posterior wall of the cerebellar cyst was removed so that it communicated with the cisterna magna. All three patients recovered and have been well for many years.

Encephalitis with Papilledema: Picture Causing Suspicion of Intracranial Tumor: Preliminary Report. J. H. Rasmussen. Ugesk. læger 118:955-957 (Aug. 16) (In Danish) [Copenhagen, Denmark].

Sixty-two patients admitted to the neurological department of Aarhus General Hospital in the three-year period beginning in 1952 presented a picture suggesting intracranial tumor. The symptoms were usually vague and had lasted for from a few weeks to a few months. Objective examination showed papilledema, in some cases also focal deficiency. Carotid angiography gave negative results. Ventriculography in 57 cases disclosed no signs of a localized, space-filling process. No evidence of intracranial tumor was found in the six patients operated on. The course of the disease was prolonged, but most of the patients were able to return to work before the papilledema disappeared. The long-range prognosis is favorable. Five patients died, 46 are well, 2 are well except for a visual defect, and in one the course is greatly protracted; in eight patients no satisfactory follow-up examination has yet been made. It is believed that in most cases there was an encephalitis with brain edema also affecting the papilla of the optic nerve as the main feature. The assumption is supported by the fact that there was an uncharacteristic febrile period in several of the patients.

Chronic Hypoventilation in an Epileptic Patient. C. E. Wells. Neurology 6:744-749 (Oct.) 1956 [Minneapolis].

Wells reports the case of a 19-year-old man in whom seizures had begun at 7 years of age. The seizures consisted of brief episodes of loss of contact with his environment, with staring or blinking of the eyelids, sometimes accompanied by head nodding and bilaterally symmetric jerks of the upper extremities. At the age of 14 he began to have rare generalized convulsions, characterized by prolonged loss of consciousness, clonic movements of all extremities, chewing motions of the mouth, and tongue biting. The patient was of normal intelligence, and no significant abnormalities were found on neurological or on general physical examination. In the course of electroencephalographic studies it was found that during periods of hyperventilation the electroencephalogram showed evidence of markedly increased activity and frequently showed paroxysmal bursts of epileptiform activity lasting 90% or more of the hyperpneic testing period. Blood electrolytes showed his venous serum carbon dioxide content to be above the range of normal. The patient was given Diamox in an attempt to alleviate the seizures, but the frequency of seizures remained uninfluenced. Although the total carbon dioxide content fell during Diamox therapy, there was no significant change in dissolved carbon dioxide as carbonic acid or in carbon dioxide tension. The author cites reports on the clinical usefulness of hyperpnea as a diagnostic method in epilepsy. Efforts have been made to prevent epileptic seizures by inducing chronic hypoventilation by means of bilateral artificial pneumothorax.

Surgical Treatment of Arteriosclerotic Occlusion of Common Carotid Artery. D. A. Cooley, Y. D. Al-Naaman and C. A. Carton. J. Neurosurg. 13:500-506 (Sept.) 1956 [Springfield, Ill.].

This report is concerned with a 71-year-old man who complained of a swishing noise in his left ear. The noise had first appeared four months previously and had steadily increased in intensity. It was synchronous with heart beat and was most annoying during periods of accelerated heart rate. The noise was accentuated by slight flexion of the head on the neck, particularly if his head was on a pillow, thus interfering with sleep. Cerebral arteriography showed a partial occlusion of the left common carotid artery beginning just proximal to the bifurcation, with satisfactory filling of the internal and external divisions. Localized aneurysmal dilatation of the internal carotid artery was demonstrated distal to the stenosis. At operation, thromboendarterectomy was performed, reconstructing the artery while a temporary external shunt was used to provide cerebral circulation. The patient was discharged from the hospital six days after operation with slight impairment of motion and sensation in the right hand. Four weeks later examination revealed normal pulsation in the left common and external carotid arteries without evidence of a thrill or bruit. The slight residual weakness in the right hand was improving, and function was almost normal.

Although this patient had no neurological deficit before operation, the results of the carotid occlusion test indicated that cerebral circulation was precariously reduced. Under such circumstances even slight reduction in cardiac output or periods of hypotension from any cause may produce temporary hemiplegia from ischemia even in the absence of complete carotid occlusion. Furthermore, the narrow lumen of the carotid artery could easily have been occluded acutely by development of a very small thrombus. If operation had been postponed until permanent damage to cerebral tissue had occurred, little could have been expected from the restoration of normal carotid circulation. The authors emphasize the fact that arteriosclerotic occlusion of the common or internal carotid arteries is not uncommon and may produce neurological symptoms of varying types and severity. Onset may be explosive in character, producing hemiplegia, or insidious, producing slowly progressive or transient symptoms. Prompt recognition of the disease and localization of the occlusive lesion permits early treatment and may prevent permanent neurological symptoms.

A Particular Variety of Headache. C. Symonds. Brain 79:217-232 (June) 1956 [London, England].

The author defines a clinical syndrome that is of comparatively rare occurrence but is recognized by many neurologists. The 17 patients discussed in this report were selected from a larger number. Attacks of severe pain in and around the eye occurred in bouts, with long intervals of freedom. The duration of the attack or paroxysm was seldom less than half an hour or more than two hours. The frequency of the paroxysms during a bout varied from less than one to eight in 24 hours. The duration of the bout was usually between two and eight weeks. The intervals of freedom lasted in most cases for more than six months and extended up to 10 years. Fourteen of the patients were males, and the average age at onset was 27. The successful treatment of this malady by preventive injections of ergotamine tartrate is described with illustrative cases.

The author believes that this particular variety of headache is a migrainous variant. The justification for regarding this variety of headache as a distinct clinical species is that, since the bouts are self-limited and seldom last more than 8 or 10 weeks, they can be treated by repeated injections of ergotamine tartrate without any harmful effects of a lasting nature. It was observed that ergotamine tartrate in solution is unstable, so that the preparation after a period of months may become inert. A patient who has previously obtained relief from the injections and who after an interval of freedom has another bout may, having recourse to an unused store of ampuls, find them ineffective. This has occurred in more than one case of the present series, the subsequent use of fresh ampuls being followed by immediate relief.

PEDIATRICS

Hormone Therapy Combined with Antibiotics in the Treatment of Tuberculous Meningitis in Children. J. Chaptal, R. Jean, Mrs. C. Campo and Mrs. D. Abram-Dossa. Pédiatrie 11:663-675 (No. 6) 1956 (In French) [Lyon, France].

Cortisone was given simultaneously with streptomycin and isoniazid in 15 cases of severe tuberculous meningitis in children whose ages ranged from 5 months to 11 years. The purpose of the cortisone was to avoid the rise in intracranial pressure and the general exacerbation of symptoms that are commonly seen during the first few weeks of antibiotic therapy in cases far advanced or not promptly diagnosed. The adverse effects of the antibiotics are ascribed to liberation of toxins from the tubercle bacilli as they undergo lysis; there may be an arachnoiditis about the cord and the base of the brain, manifested by increased albumin in the spinal fluid and leading to permanent, possibly fatal, nervous lesions. The initial exacerbation caused by antibiotics was clearly seen in three infants with the syndrome of intracranial hypertension: daily systemic administration of 50 to 100 mg. of hydrocortisone was followed by distinct improvement within a few days. In subsequent cases it was found that daily oral administration of cortisone, if begun simultaneously with the beginning of antibiotic therapy, suppressed the initial stage of aggravation, so that improvement was obtained within three to eight days. Administration of the cortisone by lumbar puncture did not benefit patients with arachnoiditis about the base of the brain but was strikingly successful in one case of spinal arachnoiditis, where the anti-inflammatory effect of the hormone was enhanced by proximity of the site of injection to the structures actually involved. The systemic route of administration is generally preferable to the intraspinal route, and hormone therapy should begin simultaneously with antibiotic therapy. If prolonged hormone therapy is necessary, the adrenocorticotropic hormone ACTH may be given alternately with cortisone. The cases here described indicate that simultaneous hormone and antibiotic therapy in tuberculous meningitis is not merely a possibility but actually, because of the great bactericidal potency of the antibiotics, a necessity.

Cystic Fibrosis of the Pancreas with Varying Degrees of Pancreatic Insufficiency. H. Shwachman, R. R. Dooley, F. Guilmette and others. A. M. A. J. Dis. Child. 92:347-368 (Oct.) 1956 [Chicago].

Seventeen children, between the ages of 2 months and 16 years when first seen, with cystic fibrosis of the pancreas were studied at the Children's Medical Center of the Harvard Medical School between July, 1947, and March, 1956. Partial or incomplete pancreatic insufficiency was a feature in all the patients; in each of them the duodenal fluid, when first examined, showed normal or near-normal proteolytic activity. The pulmonary manifestations of the disease preceded and overshadowed the symptoms and laboratory evidence of pancreatic insufficiency. Four of the patients died of extensive pulmonary infection and insufficiency, and autopsy showed marked fibrosis of the pancreas with some inspissated secretion in a number of widely dilated ducts and with preservation of acinar tissue. Six of the 14 patients who survived were followed for a sufficiently long period by repeated duodenal fluid assays to demonstrate progression from a state of partial to one of complete pancreatic enzyme deficiency. Dissociation of or lack of correlation of the activity of the various pancreatic enzymes in the duodenal aspirate was frequently noted in these patients.

The diagnosis of cystic fibrosis was made in all the patients before complete enzyme deficiency occurred. The features that led to this diagnosis in patients who had only the pulmonary features of cystic fibrosis were positive family history, abnormally increased viscosity of duodenal fluid, scant flow, dissociation of enzyme activity, failure of normal enzyme response to intraduodenal instillation of olive oil serving as a pancreatic stimulus, loss of enzyme activity in successive tests over a period of months or years, and abnormal results obtained from gelatin and vitamin A–absorption tests. When the sweat test was made simple, reliable, and practical, the patients in whom a diagnosis of partial pancreatic insufficiency had been made were recalled for study. In each of 15 patients tested the findings for the sweat sodium and chloride concentration were characteristic of patients with cystic fibrosis having complete pancreatic deficiency. It has been estimated that from 10 to 15% of 500 patients with cystic fibrosis studied during the past nine years had minimal or no discernible evidence of pancreatic enzyme deficiency.

The observations made in the 17 patients are opposed to a hypothesis for this disease, that places the initial or primary defect in the pancreas. Pulmonary lesions may appear long before pancreatic enzyme deficiency can be detected by current laboratory tests or by clinical observation. The severity and extent of the pulmonary lesion is independent of the status of the pancreas. Caution is suggested in the use of a trypsin assay of the duodenal fluid as a reflection of pancreatic function. The marked fluctuation in activity of this organ and the wide normal range of activity of some individual components must be considered in evaluating the pancreatic status. A number of tests reflecting different functions of the pancreas, such as the so-called direct tests including measurements of protease, amylase, lipase activity and the response to intravenous administration of secretin or intraduodenal instillation of olive oil, and indirect tests including absorption tests (fats, vitamin A, and proteins), may provide a truer index of the status of the pancreas. The prognosis in cystic fibrosis does not depend on pancreatic insufficiency but rather on the pulmonary involvement. The recognition of cystic fibrosis in patients with varying degrees of pancreatic involvement permits the institution of therapy directed toward the pulmonary infection and mechanical obstructive phenomena. It was this approach that accounted for the survival of most of the patients with extensive pulmonary involvement reported on.

Migraine in Childhood: A Preliminary Report. E. C. Burke and G. A Peters. A. M. A. J. Dis. Child. 92:330-336 (Oct.) 1956 [Chicago].

A diagnosis of migraine was made in 92 of about 60,000 children who were examined in the section of pediatrics at the Mayo Clinic in the course of a six-year period. There were 63 boys and 29 girls, and their age varied between 1½ and 14 years. Positive histories of migraine in members of the immediate family and grandparents were obtained in 40 children. Frontal or orbital headaches were described by 63 children, and in 13 others the headaches were unilateral or occipital. The most distressing symptoms were nausea and vomiting, which were present in 74 children. Only nine children described symptoms of scotoma, and nine others complained of blurred vision. Coexisting convulsive disorders were present in 7 of 18 children who had associated neurological features, such as numbness in the arms or hands, hemiplegia, expressive aphasia, amnesia, homonymous hemianopsia, and a hissing sound in the ears. A strikingly high incidence of abnormal tracings was noted in 46 of 67 children from whom electroencephalograms were obtained. Twenty-two children had manifested vascular changes about the temple or face. These were described at various times as a flushing of the face or temple, an ashen-gray pallor, or bloodshot eyes. The frequency of occurrence of migrainous attacks ranged from attacks nearly every day to one every month. In 26 children attacks of migraine were definitely associated with such precipitating factors as excitement, school examinations, family strife, a new dress, a trip to the barbershop, or other emotional factors. Physical exertion and fatigue, television, movies, or bright sunshine were also precipitating factors.

Migraine occurs oftener in children than is appreciated. Children with migraine have scotoma less frequently than do adults with migraine. They also have less cephalgia, but more gastrointestinal symptoms, than do similarly afflicted adults. The migrainous child has attacks more frequently than does the adult with migraine. Boys were more frequently affected than girls. Migraine is a vascular phenomenon of unknown cause. Psychogenic factors appear to play the greatest role in precipitating attacks. Elimination of these factors and an understanding of the mechanism of the attacks are essential for both patient and parents. The study of migraine is complicated because of numerous functional aspects in the headaches of these children as a group.

The prognosis for disappearance of attacks cannot be given with statistical proof at this time. Additional studies concerning this aspect of the problem are indicated. The authors recommend administration of acetylsalicylic acid (Aspirin), a combination of ergotamine tartrate and caffeine (Cafergot), and the use of diphenylhydantoin sodium (Dilantin). A trial of anticonvulsant drugs in adequate doses is suggested as a prophylactic measure.

"Periodic Peritonitis." G. S. Sturtz and E. C. Burke. A. M. A. J. Dis. Child. 92:390-394 (Oct.) 1956 [Chicago].

The authors describe three cases of periodic peritonitis in a 6-year-old boy of Armenian extraction, an 11-year-old boy of Syrian extraction, and an 11-year-old Jewish girl. Periodic peritonitis is characterized by recurrent bouts of abdominal pain, abdominal tenderness, fever, polymorphonuclear leukocytosis, and at times, pain in the thorax and joints. The duration of the attacks may vary from 24 to 72 hours; it is followed by complete remission, but exacerbations occur at regular intervals. The recurrences at times may be irregular, and the remissions may become shorter with age. The three cases appear to be the first reported in the American pediatric literature, but the syndrome is familiar to internists in the United States and to physicians in the Near East and North Africa. It often occurs in families. In most reported cases the disease has afflicted Armenians, Jews, and Arabs. The paroxysms recur over many years and are unaffected by any treatment. There is no appreciable effect on the general health or growth or development of afflicted children. The cause of this syndrome is unknown.

The younger of the two boys had an exploratory laparotomy between attacks. His abdominal organs and peritoneum were grossly normal. The older boy who was operated on during an attack of abdominal pain and fever had peritonitis grossly. The reaction was severest around the spleen and gallbladder. It appears that patients operated on during an attack often have acute peritonitis and sometimes superimposed chronic peritonitis, while those who are operated on during remission may have chronic peritonitis or no peritoneal abnormality at all. Knowledge of this syndrome may allow the physician to recognize the fact that a patient has an attack. Exploratory laparotomy, however, may be necessary in some cases, if localizing signs develop, to rule out concomitant acute surgical disease.

OPHTHALMOLOGY

Retinopathy in the Premature. G. P. Sourdille, M. Pasquier and J. R. Grislain. Semaine hôp. Paris 32:2771-2778 (Sept. 10-14) 1956 (In French) [Paris, France].

Retinal disease of the newborn, unknown at Nantes before the creation there of the premature center in 1951, appeared in 56 infants during the four-and-a-half-year period from March, 1951, to October, 1955. Complete retrolental fibroplasia developed in 13, partial fibroplasia in 5, and regressive retinal disease that disappeared without sequelae in 38. The 13 infants with complete retrolental fibroplasia constituted 2.2% of all 600 premature infants examined and discharged alive during the period in question, but when only the 330 infants weighing less than 2,000 gm. are considered, the percentage is 4.3.

The variable effect of the disease on ocular function, ranging from normal vision to complete blindness, has led to attempts to determine the prognostic significance of the ophthalmoscopic findings. Rapidity of development, vitreous disturbances, vascularization of the iris, and tight miosis responding poorly to atropine seem to be unfavorable findings, but none is certainly so, and all must be interpreted in connection with the infant's birth weight and any possible toxic or infectious complications. Severe retinal disease in 17 infants was associated with a toxic syndrome and serious diarrhea in 7 and with severe persistent jaundice in 4. By contrast, only two cases of complete retrolental fibroplasia and three that were partial occurred in infants weighing 1,000 to 1,500 gm. whose hospital stay was uncomplicated by toxic or infectious incidents. Toxicity and infection undoubtedly predispose premature infants to retinal disease and aggravate the retrolental lesions when they occur.

The only effective treatment is preventive. The use of oxygen, which is unquestionably injurious to the retina of the premature infant, should be reduced to the minimum. A policy of giving oxygen in small amounts for short periods only was adopted at the premature center in October, 1954, and since then not a single case of complete or partial retrolental fibroplasia has been seen, and even the regressive forms have disappeared.

Factitious Improvement in Vision: Studies in the Pathological Physiology of the Arterioles and Capillaries. Jean-Gallois. Presse méd. 64:1528-1530 (Sept. 22) 1956 (In French) [Paris, France].

Patients with objectively demonstrated impairment of eyesight have been observed repeatedly to manifest functional improvement after the administration of vasodilating drugs without any corresponding improvement in the underlying disease of the eye. The functional improvement, though generally transient, has in some cases been long lasting. Three instances are briefly noted here. One patient had chorioretinitis; the second, amblyopia without visible lesion; the third, vascular changes in the retina. All received nicotinic acid; the third received, in addition, glutamic acid and a collyrium containing 1% potassium iodide. In each, the functional improvement was definite and prolonged.

Differential Diagnosis of Hysteria and Malingering in Functional Amblyopia: Report of a Case. H. A. Lincoff and J. Ennis. Am. J. Ophth. 42:415-421 (Sept.) 1956 [Chicago].

A diagnosis of functional blindness is the most that can be obtained by the various visual tests. For the further differentiation between the hysteric and the malingerer, other factors must be considered. In the case presented, visual testing established the presence of functional amblyopia in a young boy. The patient then admitted that he had profited from his disability, which would seem to indicate that he was a malingerer. Further examination revealed, however, that the basic disorder was hysterical. The differential diagnosis of hysteria and malingering is theoretically clear-cut. It is the difference between simulation in malingering and unconscious determination in hysteria. In practice, however, the delineation is not always so sharply and easily made, since there are varying degrees of awareness of the secondary gains in hysteria. The two conditions are most readily confused by those who mistakenly consider all hysterics as malingerers who can volitionally control their symptoms. Discrepancies, contradictions, and bizarre exaggerations of symptoms, are suggestive of malingering. The absence of much anxiety about symptoms, as in the reported case, is indicative of hysteria. The reoccurrence of anxiety following the cure of the visual defect further indicates the defensive nature of the symptom and reinforces the impression of hysteria, as does the patient's extreme suggestibility, indicated by his initial iatrogenic and later therapeutic responsiveness. Finally, data from the history and psychological testing revealed evidence of much repression of anxiety-provoking impulses, a finding always present in hysteria.

The Scleral Insert (Sclerocleisis) for Glaucoma: A Preliminary Report of Three Cases. A. B. Vicencio. Am. J. Ophth. 42:402-405 (Sept.) 1956 [Chicago].

The scleral insert or "sclerocleisis" follows the principle of iridencleisis and is similar to the techniques employing inserts and setons by which a filtering channel is obtained between the anterior chamber and the subconjunctival space. A limbus-based conjunctival flap is incised, dissected, and folded over the cornea below, as for iridencleisis. A half-thickness lamellar scleral strip about 3 mm. wide and 6 mm. long (giving allowance for shrinkage) is dissected by a no. 15 Bard-Parker knife from above downward, the base of the scleral flap being attached to the limbus. Just anterior to the base of the strip of sclera (1 to 2 mm. is the best) a keratome incision is made at the limbus, 3 to 4 mm. long, and into the anterior chamber. With fine forceps, the very soft and pliable scleral strip is easily inserted between the sclerocorneal incision into the anterior chamber. The conjunctival flap is closed with continuous silk sutures. The basic difference between iridencleisis and sclerocleisis is that, in the former procedure, the iris is pulled out of the anterior chamber and, in the latter, the scleral strip is pushed into the anterior chamber. The author presents the histories of three glaucoma patients in whom sclerocleisis was performed. The results appear to be promising.

INDUSTRIAL MEDICINE

Pneumonoconiosis Due to Inhalation of Abrasive Powder by Anergic Person: BCG Vaccination. R. E. Vaccarezza, F. A. Dubra and C. Urtubey. Rev. Asoc. méd. argent. 70:189-192 (July 15-30) 1956 (In Spanish) [Buenos Aires, Argentina].

A woman 20 years old started to work in a factory turning out abrasive soap. At the end of 3½ years she began to complain of backache, weakness, and loss of weight. She had no contact with tuberculous patients. Roentgen examination of the chest showed pure pneumonoconiosis of a confluent nodular type. The erythrocyte sedimentation rate was accelerated. Work was immediately discontinued. The severity of the pneumonoconiotic lesions was in contrast with the lack of clinical symptoms and respiratory difficulty. Repeated tuberculin tests and investigation of the gastric contents for tubercle bacilli gave negative results. The results of BCG vaccination were negative for 35 days, after which the vaccinal nodule appeared and tuberculin allergy became evident. The treatment consisted of rest and of administration of vitamins and liver extract injections. Serial roentgenograms taken during the four-year follow-up period showed massive fibrosis of a pure pneumonoconiotic type that progressed slowly. An attenuated tuberculin reaction persists. Pure pneumonoconiosis of a massive fibrous type may develop in the absence of pulmonary tuberculosis. The progress of the pulmonary lesions continues even if the patient no longer breathes an atmosphere laden with quartz. Pulmonary tuberculosis does not predispose to pneumonoconiosis, but pneumonoconiosis predisposes to pulmonary tuberculosis. Pneumonoconiosis, as a complication of pulmonary tuberculosis, aggravates the pulmonary tuberculous lesions. BCG vaccination does not change pure pneumonoconiotic lesions into pulmonary tuberculosis with pneumonoconiosis. The sedimentation rate of the erythrocytes can be accelerated in either or both pure pneumonoconiosis and pneumonoconiosis with pulmonary tuberculosis. Therefore, it cannot be used in the differential diagnosis of these two forms of pneumonoconiosis. Measures for industrial prevention of pneumonoconiosis include the following: (1) BCG vaccination of anergic applicants for work in industries dealing with quartz (the vaccination should be given several months before the applicant starts work), (2) treatment of pulmonary tuberculosis for workers in whom primary infection is detected, and (3) nonemployment of persons with grave sequels of pulmonary tuberculosis in industries in which quartz is handled.

Trichloroethylene Poisoning. H. B. Stentiford and C. J. H. Logan. Lancet 2:659-660 (Sept. 29) 1956 [London, England].

A 22-year-old man was in deep coma when hospitalized. About 1½ hours before he had drunk some cleaning fluid obtained from a clothing factory where he had been employed. It was later estimated that he probably ingested nearly 5 oz. of trichloroethylene. He behaved normally for a minute or two, but then stood up, staggered across the room, fell to the floor, and became unconscious. His breath smelled strongly of trichloroethylene. He was pale and sweating, and his jaws were tightly clenched. There was no response to painful stimuli, his limbs were flaccid, and his tendon reflexes were difficult to elicit. The pupils were eccentric and contracted and reacted only slightly to light. The plantar reflexes were equivocal. His pulse was regular; respirations were gasping at a rate of 60 per minute. The patient's stomach was washed out, and an airway was inserted. Fifty milliliters of a 50% dextrose solution was given intravenously, and two further injections of 200 ml. of the solution were given 4 and 12 hours later. Oxygen was given by mask. A semicomatose condition persisted on the day following admission. On the fourth day, the patient was rational. The history of this patient revealed that in 1952 he had been admitted to another hospital after accidentally ingesting an unknown quantity of the same fluid.

The liver function tests showed no gross abnormality, and this is in agreement with observations by other workers, who have shown that trichloroethylene, unlike chloroform, carbon tetrachloride, and tetrachlorethane, to which it is chemically related, is not very toxic to the liver. Liver damage in industry has, however, been reported in poisoning by inhalation. Cardiac arrhythmia is sometimes observed when trichloroethylene is used as an anesthetic, and this patient showed definite but transient prolongation of the PR interval in the initial electrocardiogram and intermittent periods of rapid heart action. It is apparent that with adequate therapy complete recovery from trichloroethylene poisoning may take place despite long-continued coma.

THERAPEUTICS

Pancreatic Dornase Aerosol in Pulmonary, Endotracheal and Endobronchial Disease. E. E. Cliffton. Dis. Chest 30:373-384 (Oct.) 1956 [Chicago].

One hundred four patients were given inhalations of 100,000 units of pancreatic desoxyribose-nuclease (Dornase) dissolved in either 5 or 2 cc. of diluent; 2 or 3 cc. of the solution was administered with the aid of an aerosol inhaler using oxygen for nebulization. Sixty-five of the 104 patients were given pancreatic Dornase inhalations before local anesthetization in preparation for bronchoscopy, and the remaining 39 patients with uncontrolled pulmonary complications or disease were treated with pancreatic Dornase aerosol inhalations. Bronchoscopies were completed in 56 of the 65 patients, and 28 of these were ultimately proved to have carcinoma of the lung; 20 (71%) of the 28 had positive or suspicious results from cytological examination. None of the patients had false-positive results from the cytological examination. No untoward reactions to the pancreatic Dornase inhalations were observed in these patients. Of the 39 patients who were given pancreatic Dornase inhalations for treatment, 4 had lobar atelectasis, 4 had thick mucoid secretions and segmental atelectasis associated with serious chronic disease, 8 had thick tenacious sputum and/or segmental atelectasis or pneumonitis after thoracotomy with rib resection, 10 had advanced intrathoracic carcinoma, 3 were patients with tracheostomy, and 10 had miscellaneous conditions. Thirteen of the 39 patients were cured of the pulmonary complication or disease, 12 were permanently improved, 8 were improved temporarily, 3 were unchanged, and in 3 satisfactory evaluation of the results was not possible. Patients with acute pulmonary disease such as atelectasis secondary to mucus plugs or thick tenacious sputum responded most rapidly and satisfactorily to the pancreatic Dornase. Those with more chronic disease responded more slowly but remarkably well, while those with advanced malignant disease or chronic pulmonary disease with dry cough, such as postirradiation bronchitis, responded less satisfactorily or poorly to the drug. Even with repeated inhalations and repeated courses of inhalations, only a few patients had minor complications. Pancreatic Dornase would seem to be particularly useful in patients after thoracic surgery and in patients with post-traumatic thoracic injuries.

Sensitization and Subsequent Desensitization to Probenecid (Benemid). C. R. Austrian and W. P. Boger. A. M. A. Arch. Int. Med. 98:505-509 (Oct.) 1956 [Chicago].

A 65-year-old man with chronic tophaceous gout received 2 gm. of probenecid daily for 10 days and thereafter 1 gm. for an additional 20 days; a total dose of 40 gm. of the drug was given over a period of one month. No undesirable side-effects were observed. Ten months later, when treatment with the drug was reinstituted, marked itching of the feet, swelling of the face and scalp, and giant generalized urticaria developed within 30 minutes after the ingestion of a single dose of 0.5 gm. of the drug. Shortly thereafter there was profuse sweating, faintness, pallor, tachycardia, and a marked fall of blood pressure. These signs subsided gradually in the course of 12 hours after the administration of tripelennamine, but a moderate febrile reaction persisted for 24 hours.

In an attempt to desensitize the patient, whose sensitivity to probenecid was thoroughly established by the violent systemic response to the drug, an initial dose of 2 minims (0.12 cc.) of an aqueous solution of probenecid that contained 5 mcg. per cubic centimeter was given orally, and on each succeeding day thereafter the dose administered was increased in amounts of from 1 to 3 mcg. until 15 mcg. was given. Thereafter the increments were from 5 to 20 mcg. until the daily dose was 150 mcg.; this was increased daily by 250 mcg. until a dose of 2 mg. was reached on the 38th day. The patient then was given a daily dose of 15 mg. in capsules, and that amount was kept fixed for 10 days because of recurring mild urticaria, and for one day the amount administered was reduced to 7.5 mg. That the patient was sensitive to the chemical itself and not to some excipient in commercial tablets was thus confirmed. Thereafter the administration of the drug in encapsulated form was increased by 5 mg. daily until a dose of 75 mg. was reached, and then the rate of increase was about 10% daily, until, 99 days after the procedure was initiated, 2 gm. was given daily. After desensitization the patient was able to take the full probenecid dose with the expected benefits of such treatment, i. e., control of hyperuricemia, diminution and disappearance of established tophi, a decreased incidence of acute gouty attacks, and an increased sense of well-being.

QUERIES AND MINOR NOTES

HYPOMETABOLISM AND HYPOTHYROIDISM

To the Editor:—*A 27-year-old man 6 ft. 3 in. (190.5 cm.) tall, weighing 145 lb. (65.8 kg.), has been thin all his life, even though he eats well. He works long hours and has no specific symptoms, other than tiredness, which he attributes to the work and to lack of sleep. He has a basal metabolic rate of −29%. Would the administration of thyroid in small quantities be recommended?*

Manfred Thurmann, M.D., St. Louis.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—It would seem that the administration of thyroid in this situation would be unjustifiable until further study of the patient was carried out and a true need demonstrated. Too frequently desiccated thyroid is given as a "therapeutic trial" and thus a sequence of injudicious management evolves without proved need. The taking of thyroid may "pep up" the individual, whether he is hypothyroid or euthyroid. He may thus be given a crutch he does not need. Suppression of the normal thyroid function will occur, and a true physiological, but temporary, hypothyroid state will occur when an attempt is made to withdraw the thyroid medication. Such therapy once started makes the original uncertainty more difficult to clarify.

Certain matters in this case need clarification. If there are no other symptoms or physical findings suggesting thyroid insufficiency, one might be skeptical of the need for thyroid medication. There is a difference between secondary fatigue resulting from excessive work and insufficient rest and primary fatigue that hampers the individual's ability to work. Does rest have any effect on this man's fatigue? A short therapeutic trial might be useful.

The determination of basal metabolic rate, the only test used here thus far, may be decidedly misleading. Although false-high results are more common than false-low results, it would be wise to repeat the test. The first determination is often particularly misleading. Since the basal metabolic rate at hand is not supported by the clinical impression, a second laboratory (where many tests are run) should be selected. One reason for a low basal metabolic rate is constitutional thinness, which might be the explanation for the reported result in this patient. If the low basal metabolic rate is confirmed, further tests are indicated. Tests for either radioactive iodine (I^{131}) uptake or protein-bound iodine level, or both, should be performed. These tests are also subject to error, but the three should certainly clarify the issue with considerable finality. The cost in time and money to the patient will be far less than that resulting from prolonged medical attention, which will evolve if the patient is unjustifiably tagged with a diagnosis of thyroid insufficiency.

Answer.—In a patient with a basal metabolic rate of −29% the test should be repeated several times, to be sure of accuracy. If the metabolism continues in this low range in an otherwise apparently normal 27-year-old man, it may suggest hypometabolism, in which case, a trial of therapy with triiodothyronine, 25 mcg. two times daily for two to three weeks, should be given, after which the metabolic rate should be rechecked. Determination of serum protein-bound iodine level as well as cholesterol level would help ascertain whether the patient is hypothyroid or has hypometabolism. Desiccated thyroid would be of benefit if the patient has hypothyroidism but would be of little, if any, benefit if the patient has hypometabolism. In hypometabolism, the serum protein-bound iodine level and the serum cholesterol level are normal and the metabolic rate continues to be low. In hypothyroidism, either primary or secondary, there is a decrease in the serum protein-bound iodine level as well as a low basal metabolic rate and the serum cholesterol level is usually elevated.

APPEARANCE OF A SIGNIFICANT Q WAVE

To the Editor:—*When a Q wave develops as a result of myocardial infarction, is it permanent? What conditions can bring about a change in a Q wave? The patient whose case prompted this question is 60 years old and had the clinical appearance of a mild myocardial infarction with precordial pain radiating to the left arm. The electrocardiogram showed Q waves in leads 3 and AVF as the only change from a previous record taken eight months before, and a posterior wall infarction was diagnosed. However, a few days later these Q waves had disappeared and acute cor pulmonale was then diagnosed, supported by such clinical signs as rales in the left lung and a small pleural effusion on x-ray. However, two weeks later, the Q wave reappeared in leads 3 and AVF and deeply inverted T waves in V5 and V6; the T waves seemed typical of the evolution of an infarct. The stumbling block in the diagnosis of an infarct, in my opinion, is the period when Q waves were absent.*

M.D., Connecticut.

Answer.—The appearance of a significant Q wave in the electrocardiogram in a lead in which it did not previously exist brings to bear strong evidence to support the diagnosis of myocardial infarction. The Q wave occurs because of the presence of electrically inactive tissue beneath the electrode in the case of a so-called unipolar lead or in the plane of electrical activity in a bipolar lead. The appearance or disappearance of a Q wave in lead 3 alone is of minor significance. However, when such a change is associated with the appearance of a Q wave in AVF, there exists strong evidence of the presence of a posterior myocardial infarct. Lead AVF is inscribed from an electrode that faces the posterior-inferior (diaphragmatic) surface of the heart. If the position of the heart be altered, with respect to the electrode, the portion of the heart that faces the electrode will be a different one. The position of the heart may be altered by a difference in the position of the patient at the time of different electrocardiograms, by the presence of pressure from below the diaphragm (ascites, distention of the intestine), by an altered pressure in the mediastinum (pneumothorax, atelectasis), or by an infarct of the myocardium that causes the altered muscular contraction to produce cardiac rotation. If any of these phenomena produced a change in the relationship between the surface of the heart and lead AVF, the pattern of AVF might well be altered. When any of these causes becomes adjusted, the original pattern of the electrocardiogram is likely to be restored. In the present case, the later development of T wave changes in V5 and V6 strongly suggests the presence of a posterolateral infarct.

FEEDING GARBAGE TO PIGS

To the Editor:—*In some states garbage has to be cooked before it is given to pigs. Do pigs get food poisoning when they eat spoiled meats and vegetables and rancid fats? What about broken glass and bottles? Frequently when we have a run of ants in garbage, chlordane ant powder is put in and around the garbage can. What happens when pigs eat this and other poisons in garbage?*

M.D., California.

Answer.—The problem of feeding raw garbage to swine has, in the past, presented economic and public health problems. Studies have indicated that swine have become infested with Trichinella and infected with virus causing vesicular exanthema due to the consumption of raw garbage. Studies made by the United States Department of Agriculture indicate that the eradication of vesicular exanthema would be impossible as long as the practice of feeding raw garbage to swine is con-

---

The answers here published have been prepared by competent authorities. They do not, however, represent the opinions of any medical or other organization unless specifically so stated in the reply. Anonymous communications and queries on postal cards cannot be answered. Every letter must contain the writer's name and address, but these will be omitted on request.

tinued. At present 46 states require that all garbage be cooked at a temperature of 212 F for 30 minutes. The effective cooking of garbage destroys all viruses and pathogenic organisms and prevents illness of swine and the subsequent economic loss due to death of animals.

A search of the literature failed to indicate data as to the effect of the use of poisonous insecticides on garbage that is subsequently used for hog feeding. However, where garbage from many sources is combined and cooked prior to feeding, the problem would be minimal, due to the reduction in the concentration of the economic poison to a point far below toxic limits. All users of garbage destined for swine feeding require separation of glass and metal from the garbage prior to collection. Glass and metallic particles are heavier than the organic wastes comprising garbage and therefore lend themselves to easy separation during the garbage cooking operation. Removal is effected either through apertures in the base of the cooking vat or by utilizing a simple trap in the vat.

METASTASIS OF BREAST CARCINOMA

To the Editor:—*A radical mastectomy was performed for carcinoma of the left breast in a woman 35 years of age who had delivered her first child one week before the operation. She noted the lump on the medial aspect of the breast about two weeks before delivery but did not tell her physician about it until just after delivery. There were no positive nodes in the left axilla. The case was discussed with a radiologist, and it was decided that x-ray therapy would probably be of no avail. Eight months later a nodule was palpated in the right axilla. Frozen section showed this to be a metastatic lesion, and a radical right mastectomy was performed. There was no evidence of carcinoma in the right breast clinically or by microscopy, but positive nodes were found in the right axilla. A preoperative x-ray of the chest showed a small suspicious but not definite area in the mediastinum. The lung fields were clear. A bilateral oophorectomy was performed one week after the second mastectomy. Should she have x-ray therapy now, or should she wait for definite evidence of metastasis? If it is advisable to use x-ray therapy now, where should it be given and what dosage would be prescribed?*

M.D., Pennsylvania.

Answer.—Nothing should be done for the present, until the effects of the oophorectomy can be appraised. If localized metastasis appears, x-ray therapy may be tried to the area. If widespread metastasis occurs, a trial of therapy with cortisone, 100 mg. daily, should be given and continued as long as there is benefit. When any beneficial effects of the above treatments are gone and the patient is in relapse again, a hypophysectomy should be done.

NEURALGIA AFTER LAMINECTOMY

To the Editor:—*A patient had a laminectomy 10 months ago for intractable pain. A degenerated disk was found at the fifth lumbar vertebra and removed. She has since been relieved of sciatica but has developed a burning and neuralgic type of pain along the femoral and sciatic nerves of the right leg. A neurosurgeon felt that this was due to inflammation of nerve roots and associated spasms and would be many months in resolving. The reflexes returned to the affected leg and skin sensation is normal. He did not feel that there was any nerve root compression. He gave her Arlidin, which would help to relieve the spasms. She requires ¼ grain (15 mg.) of morphine every day or so to remain free of pain. If this is withdrawn, she exhibits no withdrawal symptoms and the pain will diminish after a few days of absolute bed rest. Please give suggestions as to the treatment and prognosis of this neuralgia.*

James D. Wilson, M.D., Greenville, Miss.

Answer.—The return of reflexes and sensation would indicate that there is very little if any nerve root compression, and one would then project a good eventual prognosis. If the pain disappears on bed rest, a factor in its etiology is probably a weak musculature. This could be overcome by postural exercises. The most important would be straight leg raising while lying on one's back, with the hope of strengthening the abdominal muscles. Assuming a posture that removes the lumbar lordosis is a goal toward which to strive. The exercises and posture should become a part of the morning ritual. Analgesics such as aspirin should be substituted for narcotics, and a brief trial of therapy with a tranquilizing drug could be considered.

SUDDEN LOSS OF VISION

To the Editor:—*A 39-year-old woman, mildly hypothyroid, taking 2 grains (0.12 gm.) of thyroid daily, had sudden partial loss of vision in the left eye. Examination showed that, where there was previous 20/20 vision, there is now 20/30 in that eye. There was occlusion of the inferior temporal retinal artery just below the area of the macula. The suggestion of a vasospasm, or thrombus, was considered. The patient showed edema typical of an infarct, extending almost to the macular area. Five days prior, she had had dental work done on the same side of her face, with various deep injections of Novocain in the area behind the left tonsil and at the inside junction of the mandible. There is tenderness of the left side of the neck directly below the angle of the jaw on the same side. The patient was given an injection of Depo-Heparin and vasodilators four times a day, and there has been no change of her condition. The questions are as follows: 1. What is the acceptable treatment in this type of case, other than that already given? 2. What is the prognosis?*

Albert C. Esposito, M.D., Huntington, W. Va.

Answer.—Usually, when a vasospasm or arterial closure has existed for a few days, there is no treatment of value. If the patient were seen extremely early, perhaps the retrobulbar injection of Priscoline or acetylcholine would be of value. Amyl nitrite inhalations have been recommended, as have ocular massage, paracentesis of the anterior chamber, and other measures designed to lower the intraocular pressure.

MILD HYPERTHYROIDISM

To the Editor:—*Is it advisable for a 22-year-old boy to study a profession, such as engineering or optometry, if he has mild hyperthyroidism? His symptoms are exophthalmos and nervousness. There is no relief from iodine therapy. The diagnosis of hyperthyroidism was made after a complete physical examination.*

M. D., Florida.

This inquiry was referred to two consultants, whose respective replies follow.—Ed.

Answer.—In view of the persistent symptoms presented by this young man, it is suggested that further study be made to rule out the potentiality of some conditions other than simple mild hyperthyroidism. A consultation at this time might indicate another diagnostic possibility or the desirability of some other form of therapeutic approach than the utilization of iodine. Mild hyperthyroidism under adequate therapeutic control should not contraindicate study for a professional career.

Answer.—Hyperthyroidism is a correctable disease. There is no reason why it should not be controlled within a period of three or four months at the most, and there is no reason why recovery should not be complete. Alternative methods of treatment are the use of the antithyroid drugs, radioactive iodine, or thyroidectomy. One would not expect complete and sustained relief from iodine therapy alone in the majority of cases. There is no reason why the presence of hyperthyroidism should in any way interfere with a boy's career.

CHOKING ON FOOD

To the Editor:—*What is the treatment for choking on food while eating, when food has entered the trachea and the patient is in acute distress with cyanosis and dyspnea?*

Rowland P. Stanley, M.D., Garden Grove, Calif.

Answer.—Aspiration of a foreign body into the trachea, occurring most frequently during infancy and early childhood, commonly produces only partial obstruction of the respiratory tract. These objects are managed best by bronchoscopy and removal. Conservative treatment of foreign bodies within the trachea is not warranted, since only rarely (less than 5% of cases) will a foreign body be evacuated spontaneously. Actually, a progressive inflammatory reaction within the tracheobroncheal wall usually fixes the food particle in its aberrant position. The uncommon occurrence of cyanosis and dyspnea due to complete obstruction of the airway immediately after aspiration requires emergency tracheostomy to avert the patient's death. Here any firm tubing, such as a fountain pen top, may be passed into the trachea by way of a vertical incision through the skin and the second or third tracheal cartilage for an airway. With restoration of respiration, the foreign material can be removed shortly at endoscopy. Thoracotomy and bronchoscopy should be reserved only for the rare cases where all attempts at bronchoscopy have failed to remove the object.

EFFECT OF ILEOSTOMY ON PREGNANCY

To the Editor:—*What are the chances of pregnancy for a 29-year-old woman who has an ileostomy following abdominal perineal resection due to ulcerative colitis at the age of 24? The ileostomy was revised in 1954. The patient now is apparently healthy and plays golf and tennis and swims. She works normally and has been happily married for two and one-half years. Will pregnancy influence her ileostomy? This patient, with type B, Rh-negative blood, was given Rh-positive blood by mistake.* T. T. Tchen, M.D., Baltimore.

Answer.—The term "chances of pregnancy" might be taken to mean either the patient's ability to conceive, or the likelihood that a gestation will progress without special complications. As to the first question, there is the possibility that peritoneal adhesions, resulting from the colitis or from the extensive surgery performed, may have sealed the tubes or interposed adhesions between them and the ovaries. As to the second, this consultant thinks that serious difficulties would not be encountered. Both the abdominal wall and the viscera adapt themselves remarkably well to the altered mechanical conditions created by the growing uterus. If the patient's husband is Rh negative, no harm can come to her baby, and trouble is not inevitable if he is Rh positive and heterozygous. But if he is Rh positive and homozygous (the chances of this are about 50%), then the titer of Rh antibodies in her blood, probably low at present, is almost certain to rise during pregnancy and may well reach a level at which the baby will be gravely endangered.

PROSTATIC HYPERTROPHY NOT RELATED TO SEX HABITS

To the Editor:—*Are there any extensive studies of the sex habits of men who have prostatic hypertrophy? Is there any correlation between the number of emissions during the 10-to-30-year period prior to the time the prostatic hypertrophy becomes clinically evident?* R. R. Grayson, M.D., Perryville, Mo.

Answer.—Extensive studies of the sex habits of men in regard to hyperplasia of the prostate have been made and recorded. There is no evidence that sexual activity per se and the activity of sex as such has any influence on the development of prostatic hyperplasia. There is a marked racial difference in the development of prostatic hyperplasia, as evidenced by its low incidence in the Oriental and by its almost nonexistence in certain parts of Africa among the Negro race. Whether this is due to an endocrine influence is not known, but it is more probably due to that than to any activity of the glands themselves. The incidence of prostatic hyperplasia in so-called celibates is practically the same as it is in married men, who have supposedly enjoyed a normal sex life.

BLOOD CHOLESTEROL

To the Editor:—*Please tell me what influence tumors of the kidney or adrenals might have on persistent hypercholesteremia. What do you consider the normal range of cholesterol in the blood?* M.D., New Jersey.

Answer.—Tumors of the kidney are not known to produce any effect on serum cholesterol levels. Tumors of the adrenals, or hyperadrenalcorticalism, i.e., in Cushing's disease, are associated with hypercholesteremia. Treatment with hormones of the adrenal cortex, or corticotropin, according to some authors is accompanied by hypercholesteremia. However, others report no significant changes even after the prolonged administration of these hormones. The normal value for blood cholesterol in the United States according to Peters and Van Slyke is from 180 to 310 mg. per 100 cc. However, most workers in this field in recent years consider 260 mg. per 100 cc. as the upper limit of normal.

EPINEPHRINE AND REPOSITORY CORTICOTROPIN INJECTION CONTRAINDICATED IN SAME SYRINGE

To the Editor:—*Is there any incompatibility between epinephrine, 1:1,000 (0.3 cc.), and repository corticotropin injection (corticotropin gel), 40 U. S. P. units per cubic centimeter, mixed in the same syringe to be given intramuscularly for asthma?* Jacob Greenblatt, M.D., Stamford, Conn.

Answer.—There is no chemical incompatibility between epinephrine solution and repository corticotropin injection. However, there are at least two objections for this combined form of therapy. The added solution of epinephrine dilutes the repository corticotropin injection so that the effect of prolonged absorption from the latter may be disturbed. Epinephrine is designed for the immediate relief of the asthma, corticotropin for the more remote effect. Both drugs could be given at the same time (but not in the same syringe) only if the effect of each is required.

SWALLOWING AND ASPIRATION OF CHEWING GUM

To the Editor:—*What are the consequences if someone accidentally swallows chewing gum? Have cases been reported where chewing gum was accidentally aspirated?* Ernest Spitzer, M.D., St. Louis.

Answer.—Records have not been found of any unpleasant happenings after the accidental swallowing of chewing gum. This undoubtedly happens frequently in our gum-chewing population, particularly among children. Accidental aspiration is, of course, possible, and the consequences are the same as those occurring in the aspiration of any foreign body. Frequent and deliberate swallowing of chewing gum could conceivably cause a phytobezoar in the stomach. However, it is difficult to conceive of any unpleasant effects from the occasional, accidental swallowing of chewing gum.

TOMATOES AND STRAWBERRIES

To the Editor:—*What is the consensus concerning the ingestion of tomatoes and strawberries by healthy individuals? Is there any truth in the widespread belief that the former are cystotoxic and the latter nephrotoxic?* M.D., New York.

Answer.—The tomato, like the potato, is a member of the nightshade family, and, perhaps because this family is known to include several poisonous plants, the tomato was held in suspicion until the middle of the 19th century. Because the strawberry has produced hives in some persons, it, too, has been regarded with suspicion. Physicians today agree that the ingestion of tomatoes and strawberries by healthy persons is not harmful.

METALLIC TASTE IN THE MOUTH

To the Editor:—*Please discuss the cause and treatment of a metallic taste in the mouth. I have had several patients with this complaint whose teeth and mouth are normal.* R. W. Lieber, M.D., Durand, Mich.

Answer.—The cause of metallic taste in the mouth is frequently due to infection in either the nasopharynx or decayed teeth. In rare instances an allergy to food or tobacco has been described. Also, in rare instances the presence of adjacent silver and gold fillings has caused a metallic taste. However, an emotional basis is the usual cause. Investigation of emotional problems is indicated. Sedatives such as phenobarbital or the newer tranquilizers have proved successful in many cases.

Secretary Folsom Outlines Legislative Goals • •
Hospitals Asked to Set Up Pilot Projects • •
Researchers Report New Source for Cortisone • •
President Urges More Salk Vaccine Be Used • •

SECRETARY FOLSOM OUTLINES HEALTH GOALS

In several public addresses prior to the opening of Congress, Secretary Folsom gave indication of what the administration will ask of the 85th Congress in the health field. The administration's 1957 legislative goals will be outlined by the President in his State of the Union message scheduled for delivery in January. The Secretary of Health, Education, and Welfare says the administration will ask for funds to help medical schools build classrooms. During the last session the administration requested 250 million dollars for a five-year program of grants for laboratory facilities and classrooms. Congress appropriated instead 90 million dollars for three years, limited to research facilities. "We are going to recommend again that they expand that to bring it up to the full $250 million to include both teaching and research facilities because the medical schools not only do much with medical research but they train the scientists and the doctors," he declared.

As another means of encouraging expansion of voluntary health insurance, the administration will again ask Congress to authorize pooling arrangements between smaller insurance companies so that they might expand coverage. Late in the last session, Mr. Folsom's department sponsored a bill to waive antitrust laws for these companies, but it was introduced too late for action. In recent weeks Mr. Folsom has cited rapid gains being made in voluntary insurance covering major medical expenses, generally after the first $100 has been paid by the insured. When coupled with basic coverage, catastrophic insurance affords a family adequate protection, he has poined out.

Mr. Folsom also has indicated the department will ask for more funds for the next fiscal year than the 2.2 billion dollars voted by the last Congress. That figure included 1.3 billion dollars to the states for public assistance. Taking cognizance of the possibility of new demands on the budget for defense purposes, Mr. Folsom declared: "While we must maintain this defense posture . . . we want to be very careful that we don't let down on expenditures in the field of health, education, and welfare. . . . We have got to look out for our human resources." On social security changes, Mr. Folsom said the administration felt there was no need for any action, at least on old-age benefits.

PILOT PROJECTS FOR STUDY OF FACILITIES

A government advisory committee has requested that hospitals set up a number of pilot projects through which a study could be made of facilities and services for patients who need only limited care. The committee, appointed in September by Secretary Folsom and headed by Dr. Russell Nelson of Johns Hopkins Hospital, made its recommendations after reviewing preliminary facts assembled by the Department of Health, Education, and Welfare. Of the proposed hospital projects, the committee says: "These new types of units would be designed to provide a basis for further study of ways to improve care for these patients, perhaps at lower costs than would otherwise be possible."

Dr. Nelson says the committee at present is confining its consideration to the needs of three specific groups of patients: (*a*) those convalescing from acute illness, (*b*) those convalescing from chronic illness, and (*c*) those requiring only diagnostic services and facilities.

On long-range objectives, Dr. Nelson declares: "The aim of the committee is to obtain from the pilot studies practical recommendations which can be adapted with minimum cost by virtually any hospital or community to establish facilities for patients needing only limited care. On the basis of these findings, we hope agencies concerned with hospital and medical care—especially voluntary agencies—will be better able to develop similar facilities and services to meet their own needs."

NEW SOURCE FOR CORTISONE

A plant that grows in profusion in parts of Texas and is often fatal to sheep and goats promises a new, cheap, and entirely domestic source for cortisone. The Department of Agriculture, identifying the plant as Agave lecheguilla, gives this explanation: "This unwanted weed is the most promising native plant yet found to yield substances that can be converted to cortisone. . . . Chemists of USDA's Agricultural Research Service have discovered in the plant a substance known as smilagenin, from which cortisone can be made by chemical means. Although higher yielding plant-sources of cortisone-like drugs have been found, this one is potentially important because it grows in such profusion within the nation's borders. It covers thousands of square miles in the Big Bend region of Texas."

PRESENT PLENTIFUL SUPPLY OF SALK VACCINE

President Eisenhower has joined Secretary Folsom in urging young adults to have Salk vaccine injections immediately in an effort to reduce the incidence of poliomyelitis next season. Secretary Folsom reported to the President that at present 17,000,000 doses of the vaccine are lying unused in drug manufacturers' ware-

Washington News—Continued

houses. In addition the vaccine is stockpiling in drugstores and doctors' offices. Besides urging the inoculation of young adults, the Secretary recommended that "millions of children who have so far received only one or two injections should be given the additional protection provided by the recommended three doses."

Today, Mr. Folsom pointed out, the large supply of Salk vaccine provides the way to prevent paralysis or even death. The present danger is public apathy, which can be overcome by "earnest and vigorous cooperation of parents, physicians, schools, officials at all levels of government and public and private health agencies."

Recently the Commerce Department approved the export of 29,300 doses of Salk vaccine for Hungarian refugees. The shipment, enough to inoculate about 15,000 children and young persons, is being rushed to Vienna for distribution by the International Rescue Committee. The Pitman-Moore Company of Indianapolis donated the vaccine.

MEDICAL CARE COSTS

Medical care costs, which are computed in the nation's cost of living figures, rose 1.5% during the third quarter of this year, according to the Bureau of Labor Statistics. Fees charged by physicians, however, rose only 0.8% during the three-month period ending in September, the government agency reported. The over-all increase in the cost of living was 0.7% for the period.

The Bureau of Labor Statistics said medical care costs when drugs were excluded increased 0.9% in the third quarter. Fees charged by surgeons showed one of the smallest increments: 0.5%. General practitioners' fees rose 0.8% while obstetric care was up 1.7%. Major factors in bringing the over-all medical care index higher during that period were a 3.2% rise in hospital rates and a 3.9% increase in group hospitalization fees. Prescriptions and drugs rose 0.7% and dentists fees, 0.16%.

BUSINESS AND A REHABILITATION PROGRAM

Private business cannot "sit smugly back and assume that some governmental agency or institution will find the way" to rehabilitate the rapidly increasing number of disabled persons, according to an article in the U. S. Chamber of Commerce publication, American Economic Security.

The author, W. Scott Allan, points out that the present statistics of the National Safety Council list 1,900,000 work accidents in 1955 with a cost in labor hours and medical expenses of 3.5 billion dollars. The Bureau of Labor Statistics estimates that between 5 and 6 million persons of working age in the United States have disabilities that hinder their finding jobs.

The future trend "toward including the degenerative conditions, such as heart disease, arthritis and the like, under workmen's compensation, together with the recognized aging of our general as well as our working populations, means greater burdens for industry and insurance in the future," the author writes.

Mr. Allan finds that the solution to the problem is a sound rehabilitation program with business interests the focal point of community planning. Industry must train personnel officers to understand the injured worker's needs and capabilities. Community planning, plant programs, and educational campaigns can help achieve "restoration of a disabled individual to a useful and productive life . . . a goal which is economically and socially sound."

INTERNATIONAL SCIENTIFIC CONFERENCE

An international conference on scientific information is scheduled for November, 1958, in Washington, D. C., under sponsorship of the National Science Foundation, the National Academy of Sciences–National Research Council, and the American Documentation Institute. Preliminary plans for the session were made at a meeting of 50 scientists and experts in documentation, meeting at the National Academy of Sciences in Washington. Participation will be restricted to specialists in the fields to be covered by the agenda, but observers will be welcomed if they register in advance. The plan is to limit the delegate list to 150, including authors of papers and members of review panels. Copies of all papers will be mailed to delegates at least two months in advance of the conference.

PENSONNEL

Paul B. Murphy, food specialist with the Bureau of Indian Affairs, will direct an American Red Cross program for feeding Hungarian refugees. He already is on duty in Salzburg, Austria. . . . Senator Bricker is preparing a new version of his amendment, for which he will ask White House support. The objective is to forbid the signing of treaties that interfere with state or local rights. An earlier version, opposed by the Eisenhower administration. lost out in the Senate in 1954. . . . Major Gerald Champlin is the first Army doctor to complete a course at the Navy Deep Diving School. The ultimate objective is to provide Army divers with doctors who understand the special medical problems of deep-sea diving.

MISCELLANY

The first federal old-age and survivors insurance checks have already reached 300,000 women in the 62 to 64 age group. They became eligible for payments under the recent amendment to the social security law lowering the age from 65. . . . The VA advises that the best Christmas gifts for veterans who will spend the holiday season as patients in Veterans Administration hospitals are visits from friends and relatives or a long letter from home. . . . The Navy Bureau of Medicine and Surgery is planning a symposium late in January to acquaint field representatives with Bureau policy and the Bureau with field problems. . . . Two Public Health Service scientists, Drs. Daniel Steinberg and Donald S. Frederickson, report they have found a way to control in laboratory animals the natural production of cholesterol.

(cont'd)

'LANOXIN' continues to offer the same advantages — only the name has been changed.

The full effects of each dose develop quickly to permit rapid appraisal of the need for additional drug. Moreover, the limits of the patient's therapeutic range, which may be reduced in the seriously ill, may be approached with relative safety because toxicity, if it develops, soon abates. For true balance and uniformity of therapeutic effect, prescribe 'LANOXIN' brand Digoxin.

Sincerely,

'B.W.&Co.'

ADVANCED MAMMARY CANCER TREATED WITH SEX HORMONES

Edward F. Lewison, M.D., Frances H. Trimble, M.D.
and
Robert S. Ganelin, M.D., Baltimore

• *Estrogens were compared with androgens as to their effects on 133 patients with advanced mammary cancer. Estrogens should not be used for this purpose in women less than five years past the menopause; when properly used they were found to be somewhat superior to the androgens in their objective effects on lesions in soft tissues and viscera. The androgens were somewhat more potent by subjective critera. Both androgens and estrogens gave a sense of well-being and partial or complete relief of pain in about half of the patients. Regression of the tumor sometimes occurs also upon discontinuation of hormone therapy that has been ineffective or has ceased to maintain an initial improvement. Full use should be made of these profound and gratifying palliative effects of hormone therapy.*

Mammary cancer is an all-too-common universal tragedy—malign and monstrously destructive of human life. Morbidity studies for each sex in the United States[1] indicate that the age-adjusted incidence rate for cancer of the breast is considerably higher than for any other specific primary site. The breast is by far the most frequent single female organ attacked by cancer. The incidence of mammary cancer represents 21.7% of all cancers in females, and it is the leading cause of death among women in the midperiod of life, from 40 to 60 years of age.[2] It is readily apparent that in the total care of mammary cancer the palliative treatment of advanced, recurrent, and metastatic disease by means of hormone therapy has become a problem of major magnitude in clinical management. The purpose of this presentation is to describe the results of sex steroid therapy in a series of patients with this disease.

Historical Review

The intimate relationship between the breasts and ovaries was recognized without being understood for many years before the isolation of the sex hormones and the elucidation of the complex pattern of endocrine interrelationships. The earliest reported attempts to influence mammary carcinoma by physiological means were described by Beatson[3] in 1896. He had become interested in lactation in 1876 and, having observed that the cellular proliferation and desquamation of lactation were associated with a temporary cessation of ovarian activity, he hoped that a similar degeneration of epithelial cells would follow removal of the ovaries. To reinforce this effect, he administered thyroid extract to his patients postoperatively. This method of treating recurrent carcinoma of the breast was followed in Britain for many years, but, as it was never endorsed with any enthusiasm by the influential German school, its popularity waned. At a later date, castration by the simpler method of irradiation was reintroduced and in some clinics is employed as a routine in premenopausal patients with axillary metastases at the time of operation.

Meanwhile, experimental work on ovarian function was proceeding, due to the impetus given by Lathrop and Loeb,[4] who demonstrated first in 1916 the decrease in incidence of spontaneous mammary carcinoma in mice after oophorectomy. During the next decade, progress was made in the isolation of the ovarian hormones as well as in the recognition of the various components of the pituitary complex. Administration of these hormones to experimental animals suggested a cause-and-effect relationship between estrogens and mammary carcinoma, a relationship that could sometimes be altered by the use of androgens. Loeser was the first to use this observation clinically and administered androgens postoperatively to patients with mammary cancer and a strong family history of carcinoma. The dramatic results obtained in the treatment of prostatic carcinoma by castration and estrogen therapy, as outlined by Huggins and Hodges,[5] stimulated interest in this new form of chemotherapy.

The employment of estrogens in the treatment of carcinoma of the breast appears paradoxical and stems from the observations of Haddow[6] in 1935 that certain benzanthracene derivatives, already shown to have carcinogenic properties, dramatically inhibited a cer-

---

From the Breast Clinic, Division of the Tumor Clinic, Department of Surgery, Johns Hopkins Hospital and Johns Hopkins University.

tain type of rat tumor. Zondek, a pioneer in the field of endocrine physiology, in 1936 suggested the use of estrogens in breast carcinoma in an effort to suppress the secretion of gonadotropins and the growth hormone (somatotropin) from the anterior pituitary. Scattered reports of experience with estrogen therapy appeared from various centers in Britain and the United States over the years, with results that were sufficiently encouraging for experimentation with the newer compounds to continue.

The more recent approach to the problem of altering the hormone pattern really begins where Beatson left off. It has been demonstrated both in experimental animals and in human subjects that in time adrenal hyperplasia follows oophorectomy. Estrogens are produced by the adrenals, and frequently progression of the disease follows. Huggins and Bergenstal[7] suggested bilateral adrenalectomy to eliminate this secondary source of estrogen production, and about 40% of patients undergoing that procedure, mainly those who have responded favorably to oophorectomy originally, show a good but temporary response. A less formidable method of achieving a similar result is by giving cortisone, a method that is receiving careful investigation at the present time. The most recent approach, and one that appears more logical, is the operation of hypophysectomy, whereby the source of both gonadotropins and somatotropin is eliminated. The present status of this operation, with a review of about 50 patients, has recently been presented by Kennedy, Peyton, and French.[8]

Mode of Action of Sex Hormones

As is well known, the hypophysis, or pituitary gland, regulates the endocrine system of the body and is itself controlled by the hypothalamus. Throughout the reproductive years there is a delicate balance between the production of gonadotropins from the hypophysis and the sex steroids from the gonads. The reproductive system, which includes the breasts, is normally controlled by the follicle-stimulating hormone (FSH), luteinizing hormone (LH), and prolactin produced by the pituitary and the gonadal hormones estrogen, androgen, and progesterone.

In general, any increase in the amount of a particular pituitary hormone (or tropin) will lead to hyperplasia of the target gland and an increase in production of its hormones. Conversely, a deficiency in the amount of a given tropin will result in atrophy of the target organ. The administration of a target gland hormone inhibits the production of the corresponding tropin and usually alters the production of other pituitary hormones. For example, the administration of thyroid extract inhibits the secretion of thyrotropin and the follicle-stimulating hormone and stimulates the production of the other tropic hormones. The administration of testosterone inhibits the production of gonadotropic and adrenotropic hormones; an excess of estrogens inhibits the production of follicle-stimulating hormone but stimulates that of luteinizing hormone and prolactin. All cells in the body are affected by the thyroid and growth hormones, whereas the gonadal hormones influence specific metabolic processes and tissues, chiefly the reproductive system.

When castration is performed in the premenopausal subject, there is a sudden withdrawal of estrogenic compounds. Frequently this leads to a dramatic improvement in the clinical course of mammary cancer, an improvement that may persist for several months or more. However, the operation is followed by hypertrophy of the adrenals and enlargement of the pituitary gland. The adrenals are stimulated to produce estrogens by an increase in gonadotropins, and a direct stimulation of the tumor is probably produced by the increased amounts of growth hormone.

The initial effect of the absence of estrogens is to ensure a preponderance of androgens, which favors protein synthesis and osteogenesis. There is also stimulation of hematopoiesis. These same effects are obtained when androgens are administered therapeutically, as in the premenopausal patient. With the androgens acting through the pituitary, a chemical castration occurs and amenorrhea soon develops. Estrogens, however, do not completely disappear from the urine during this therapy and may be a product of androgen metabolism. The precise mode of action of the estrogen therapy used in postmenopausal patients is still not clear, but Nathanson has stated that estrogens act directly on the disease, whether in bone or in soft tissues, and that calcification and osteogenesis are secondary metabolic effects. In patients with advanced cancer of the breast tracer studies using sodium estrone sulfate labeled with radioactive sulfur (S^{35}) indicated a concentration of radioactivity in the tumor tissue.

The effect of castration, androgen, or estrogen therapy may be, as Nathanson suggested, to effect a "chemical hypophysectomy." Undoubtedly, a profound change is induced in the physiological status of the patient whereby for a time the host becomes less vulnerable to the spread of her disease and the tissues "less fit food for the cancer protozoan," as Hermann[9] postulated in 1898 in discussing oophorectomy. According to our present knowledge, this stage is time-limited and extremely variable.

Clinical Material

This study is part of a program of collaborative clinical research coordinated and sponsored by the Committee on Research of the Council on Pharmacy and Chemistry of the American Medical Association. The clinical material comprising this investigation consists of 133 women with inoperable, recurrent, or metastatic mammary cancer who received a total of 223 complete courses of hormone therapy at the breast clinic of the Johns Hopkins Hospital between June, 1947, and August, 1955.

The requisites for inclusion in this clinical investigation were formulated by the Subcommittee on Steroids and Cancer of the Committee on Research and were strictly adhered to in reporting these results. Only patients conforming to the following criteria were considered eligible for this study: First, the diagnosis of cancer of the breast must have been established by microscopic examination in all patients. Second, all patients must have had inoperable, recurrent, or metastatic disease that was no longer amenable to accepted surgical and radiotherapeutic measures. Radical mastectomy and radiotherapy are generally regarded as the treatment of choice in cancer of the breast. Patients considered "curable" by these conventional methods of therapy were not denied such measures in favor of chemotherapeutic palliation. Third, patients must not have received surgical or radiotherapeutic castration within six months prior to the onset of hormone therapy, as castration itself has long been known to be of benefit in the palliative treatment of mammary cancer. Fourth, patients must not have received radiotherapy to any lesion under observation within six months prior to the onset of hormone therapy. However, a few patients with generalized metastatic disease who received limited irradiation to local lesions were retained in the study. In these patients, only the nonirradiated lesions were observed and evaluated for their response to hormone therapy. Thus, the results of this study are believed to be independent of the effects of either castration or radiotherapy. Fifth, the minimum period of uninterrupted hormone therapy required for evaluation of results of an individual course was eight weeks. This period has been regarded as an adequate minimum time to estimate by therapeutic trial the initial effectiveness of a particular sex steroid. While some patients had only the minimum 2 months of therapy, others had continuous treatment lasting as long as 44 months. No effort was made to evaluate the results of therapy in relation to the length of time of treatment, although it is known that total dose and duration of treatment are both important. Patients who were recorded as having received more than one course of estrogens might have received the same hormone at two different periods separated by an interval of time.

Table 1.—*Treatment Schedule of 133 Patients Receiving 223 Complete Courses of Hormone Therapy*

Drug and Route	Dose	Complete Courses of Treatment, No.	
Oral			
Ethinyl estradiol	3 mg. daily	50	110 courses of androgen therapy
Chlorotrianisene (TACE)	24 mg. daily	41	
Diethylstilbestrol	15 mg. daily	9	
Parenteral			110 courses of estrogen therapy
Testosterone propionate in oil	25 mg. 3 times weekly	14	
	50 mg. 3 times weekly	3	
	100 mg. 3 times weekly	36	
	200 mg. 3 times weekly	9	
Stanolone	100 mg. 3 times weekly	17	
Testosterone cyclopentylpropionate	100 mg. once weekly	12	
Dihydrotestosterone cyclopentylpropionate	100 mg. once weekly	3	
Methylandrostenediol	100 mg. 3 times weekly	2	
Oral			
Methyltestosterone	50 mg. daily	3	
	100 mg. daily	5	
	200 mg. daily	6	
Combined therapy			
Ethinyl estradiol plus progesterone		4	13 courses of combined therapy
Ethinyl estradiol plus chlorotrianisene		1	
Ethinyl estradiol plus testosterone propionate		8	
Total		223	

Two months was carefully selected as a sufficient trial period because patients who show an objective response to therapy will do so, at least initially, by the end of that time. If regression has not begun at the end of eight weeks, our experience has shown that there is little reason to continue therapy with the same hormone over a longer period of time.

Occasional instances of "no change" (where the disease remains stationary during the period of observation) were exceedingly difficult to evaluate. Thus, it is obvious that the present series will be "weighted" with patients who have had short, nonbeneficial courses of therapy as compared to those patients showing objective improvement who have had continuous uninterrupted therapy over a long period of time.

The schedule of treatment employed in the 133 patients under study is shown in table 1. The number of courses of treatment received by each patient is as follows: 79 patients received one course of treatment, 32 patients received two, 9 patients received three, 7 patients received four, and 5 patients received five.

The particular hormone chosen for use in each patient was related to her physiological age in reference to her menopause. Prior to the menopause (whether natural or induced by irradiation or oophorectomy) and for a five-year period thereafter, the initial steroid of choice was always an androgenic hormone. After this arbitrary period (five years postmenopausal), treatment with an estrogenic hormone appeared to be decidedly more useful. However, experience has indicated that estrogens in moderate therapeutic doses when given premenopausally or in the early postmenopausal period may actually prove harmful by accelerating the course of the disease. Younger patients who fail to respond to initial androgen therapy should be given a short period of respite to allow for a "withdrawal effect" (regression of tumor that may follow the cessation of hormone therapy). After this interval these patients may be allowed a very cautious trial with estrogens in a desperate attempt to alter the tempo of this progressive and devastating disease. In place of estrogens, the adrenal steroids or endocrine ablation by surgery may be considered as an adjunct to hormone therapy at this stage of the therapeutic regimen. Androgen therapy can be used effectively in both premenopausal and postmenopausal patients, as it does not depend upon physiological age. Older patients failing to respond to initial estrogen therapy should receive a secondary course of androgens.

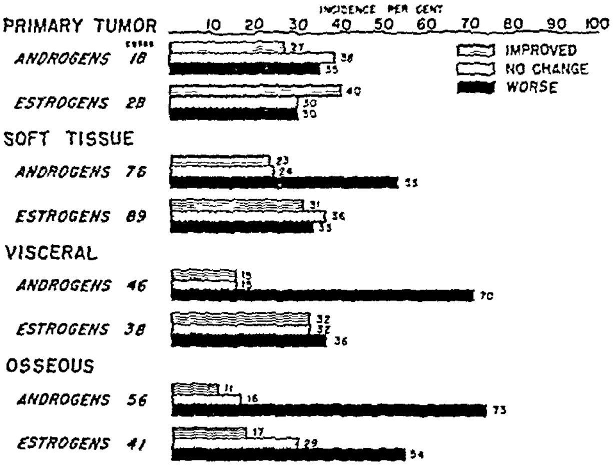

Fig. 1.—*Comparison of objective results of androgen and estrogen therapy.*

Results

Objective.—Results of therapy were compared in the following category of lesions: (1) primary, (2) soft tissue (including skin, subcutaneous tissue, and lymph nodes), (3) visceral (including pulmonary), and (4) osseous. The objective responses were recorded as improved, no change, and worse. The objective results of hormone treatment (with all treatment schedules combined and recorded as either androgen or estrogen) are shown in figure 1.

A critical evaluation of these results is difficult because of the variability in objective response as well as the inherent factor of the human equation in interpreting the findings. Patients showing definite objective improvement, even if it was followed by subsequent deterioration, were recorded as improved. On the other hand, patients whose disease appeared to remain static for a matter of months only to get worse ultimately under continuous treatment were recorded as worse. There were six such patients in the group receiving androgens and one patient in the group receiving estrogens whose disease showed no progress for periods of 2 to 10 months before advancement occurred.

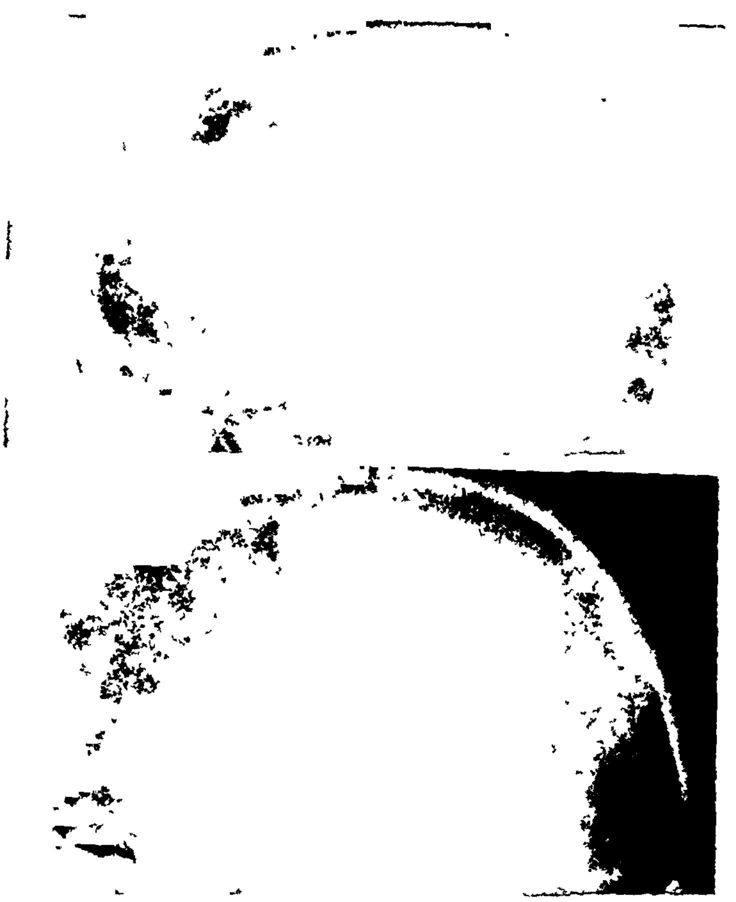

Fig. 2.—*Top,* large osteolytic skull metastases occurring while young woman was still receiving testosterone therapy. Multiple bone metastases developed after an initial favorable effect that lasted longer than one year *Bottom,* "withdrawal effect" shown by appearance of skull in same patient 6 months after discontinuation of testosterone therapy. No medicaments given during this time. Present remission has lasted longer than one year.

Evidence of a favorable objective response in the evaluation of osseous lesions requires both tumor regression and bone repair. This is usually characterized by the x-ray appearance of recalcification and increased density of osteolytic lesions, the re-formation of bone architecture and contour, and the healing of pathological fractures. These rather specific x-ray manifestations required for improvement may account for the relatively poor response shown by osseous lesions to hormone therapy. Occasionally, however, osteolytic bone lesions have been seen to undergo remarkable repair under hormone therapy, while new lesions develop or other osseous lesions progressed at the very same time. This paradox was observed in four patients under androgen therapy, and such results were reported as "worse" for the purpose of this study. Apparent acceleration of the disease occurred in two patients with osseous lesions. This required cessation of androgen therapy. Acceleration of the metastatic process has been observed in patients receiving both androgens and estrogens, but it is relatively uncommon except in premenopausal patients receiving estrogens

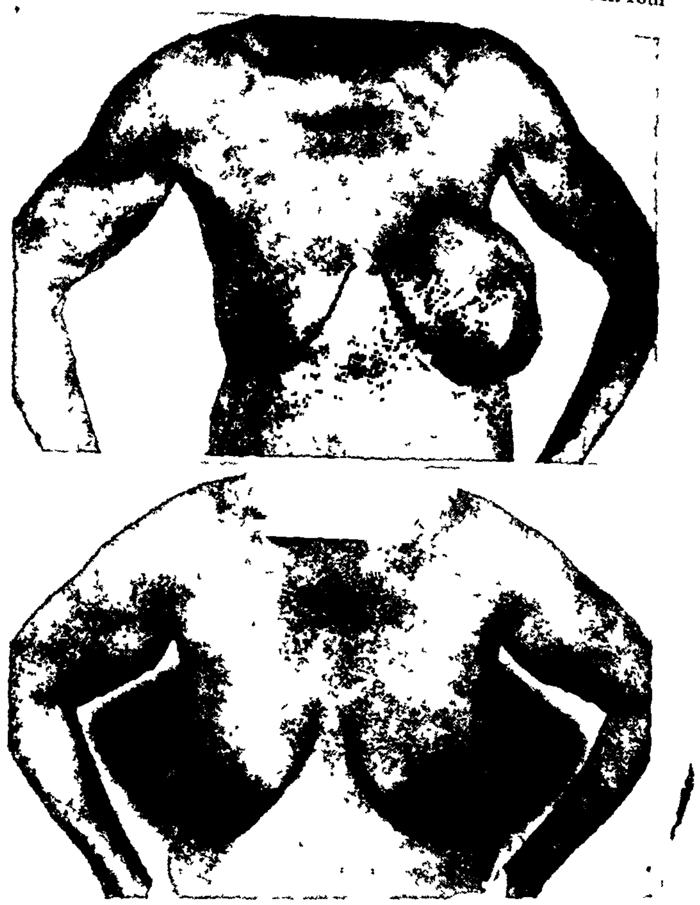

Fig. 3.—*Top,* large primary cancer of the left breast with axillary metastases. Patient considered "categorically" inoperable *Bottom,* appearance of primary tumor in same patient after 15 months of estrogen therapy. Marked regression of primary tumor and marked improvement in general appearance of patient.

TABLE 2.—*Subjective Results of Sex Hormone Therapy*

	Type of Therapy			
	Androgens (110 Cases)		Estrogens (100 Cases)	
Subjective Results	No	%	No	%
Well Being				
Improved	53	48	44	44
No change	27	25	37	37
Worse	30	27	19	19
Pain				
Complete relief	6	9	5	11
Partial relief	28	43	18	40
No change	8	12	3	6
Worse	23	36	19	43

In the palliative treatment of breast cancer one must give careful consideration to the well-recognized withdrawal effect of hormone therapy. Patients in whom the disease appears to reactivate while they are still receiving sex steroid therapy may show a marked improvement, with objective regression of the tumor, when treatment is discontinued. Huseby reported that 9 of 14 patients treated with estrogens "exhibited a second definite regression of their lesions lasting from 6 weeks to 9 months" when treatment was stopped. This phenomenon may even occur in patients who have failed to note a favorable initial response to therapy. In the present series, the favorable effects of withdrawal (of which there were several striking examples [fig. 2]) could not be included in the reported results for the obvious reason that these responses were not considered to be the direct consequence of treatment with either androgens or estrogens.

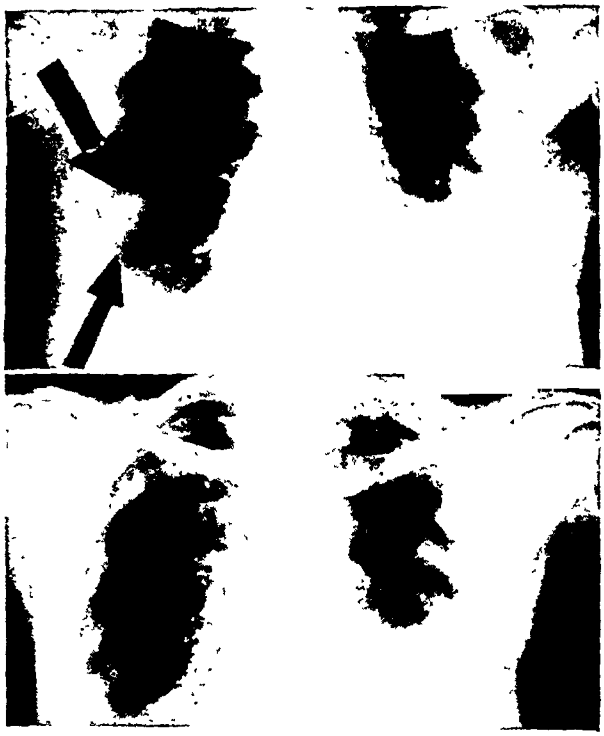

Fig. 4.—*Top*, large solitary lung metastasis in elderly woman. *Bottom*, disappearance of lung lesion after only 3 months of estrogen therapy. Patient ultimately died of liver metastases.

The results of this study (fig. 1) indicate that soft tissue and visceral lesions show a more favorable response in those patients receiving estrogens than in those receiving androgens. This superiority is considered statistically significant, as verified by the chi-square test ($p=0.05$). These conclusions are confirmed in general by the reported results of the Subcommittee on Steroids and Cancer.[10] The summary of their findings indicates that the "effectiveness of estrogen therapy for soft tissue and lung metastases increases with the age of the patient" and that in "women five years past the menopause estrogens are the hormones of choice for the treatment of soft tissue and lung metastases" (fig. 3 and 4).

In the present study, chlorotrianisene (TACE) appeared to be significantly less effective than either ethinyl estradiol or diethylstilbestrol in the treatment of visceral metastases. This finding has been confirmed by the Subcommittee on Steroids and Cancer, which found chlorotrianisene to be "unsatisfactory as an estrogenic mammary tumor-suppressant agent." Uterine bleeding was a very common complication of therapy with chlorotrianisene. In the present study there appeared to be no statistically significant difference between the several androgens used. (In the comprehensive studies of Segaloff and co-workers, the clinically effective androgens—testosterone, stanolone [Dihydrotestosterone], and methyltestosterone—share two distinctive properties: (1) they cause a decrease in the urinary gonadotropic hormone, and (2) they cause pronounced virilization.) The tumor-suppressing effect of these drugs showed no advantage over the accepted standard of reference, namely, the effect of testosterone propionate. Long-acting androgens such as testosterone cyclopentylpropionate involve certain inherent risks in the event of complications because their action cannot be interrupted promptly.

Subjective.—The subjective responses to hormone therapy were evaluated on the basis of well-being and relief of pain. These results are shown in table 2. Although a feeling of well-being was one of the most conspicuous benefits to be noted, in our experience there appeared to be very little difference in this euphoric effect between the androgens and the estrogens. However, it is well to be cautious in evaluating subjective improvement, as many steroids are known to produce a remarkable sense of well-being as a part of their anabolic effect. This can occur irrespective of the course of the disease and is particularly true with the androgens. All physicians are aware of the receptive mood of patients with incurable cancer. The power of hope in a patient with a hopeless disease is formidable; a mere placebo in a patient with advanced cancer may result in a remarkable subjective and spiritual improvement.

TABLE 3.—*Comparison of Objective and Subjective Results of Treatment with Stanolone and Testosterone Propionate*

	Results

Partial relief	13	33	9	75
No change	3	13	1	8
Worse	17	44	1	8

Relief of pain was a subjective response that seemed to be based upon a more tangible and well-defined effect. As Leriche has aptly said, the sensation of pain "is the resultant of the conflict between a stimulus and the whole individual." Pain usually occurred in patients who had osseous metastases, particularly to weight-bearing skeletal structures. As noted in table 2, complete or partial relief of pain occurred in 52% of the patients receiving androgens and in 51% of those receiving estrogens. However, in a small group of patients treated with stanolone, the complete and partial relief of pain appeared to be superior to that experienced with testosterone propionate (table 3), although the objective response in these two series was about the same.

Side-Effects

Although the usual side-effects of sex steroid therapy are quite well known, specific side-effects incident to intensive therapy often occur in the prolonged treatment of advanced mammary cancer with large and unphysiological doses of hormones. The incidence and degree of these side-effects are related to both the total dose and the duration of treatment, as well as to the individual sensitivity of the patient. The incidence of these characteristic side-effects of treatment is shown in figure 5.

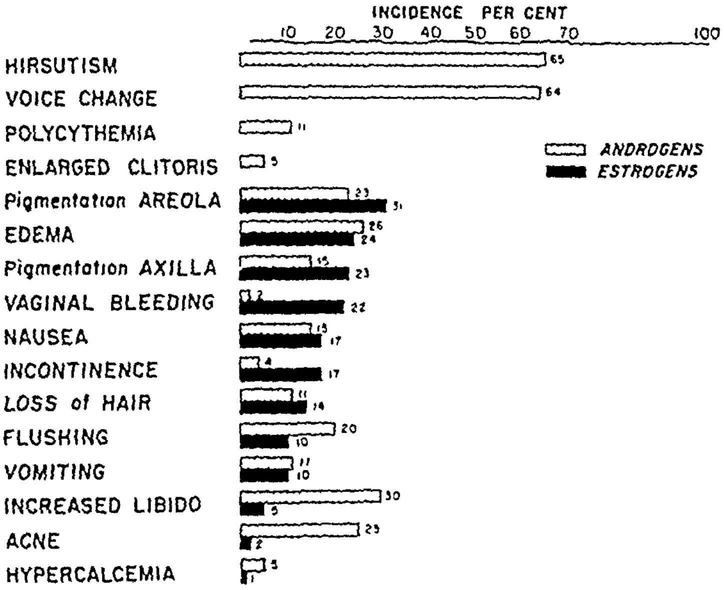

Fig. 5.—Incidence of side-effects of androgen and estrogen therapy.

Androgens.—The most prominent side-effects produced by androgen therapy were hirsutism and hoarseness, followed in frequency by increase in libido, edema, and acne. Hirsutism occurred in at least 65% of the patients treated with androgens and was most noticeable in brunette women with a natural predisposition toward excessive facial and body hair. From a cosmetic point of view this masculinizing side-effect was frequently very disturbing, particularly to younger patients. Voice changes, consisting primarily of hoarseness, occurred in 64% of those receiving androgens. This deepening of the voice is the result of hypertrophy of the vocal cords. After cessation of therapy, it often took many months before the voice returned to normal.

An increase in libido was noted in a least 30% of the patients treated with androgens. This probably represents a minimal incidence, inasmuch as many women were reticent about discussing so personal a problem. Kennedy and Nathanson,[11] in their excellent study of side-effects of sex steroids, confirm earlier findings that "androgens cause an increased susceptibility to psycho-sexual stimulation, enlargement of the clitoris and increased sensitivity of the external genitalia." Although the incidence of enlargement of the clitoris was only 5% in the present series, it must be noted that pelvic examinations were not performed routinely. Acne and a coarsening of the skin occurred in 25% of the patients receiving the androgens. This acneiform eruption varied from mild to severe, but occasionally it was pustular and cosmetically quite distressing. In those patients with severe acne, it appeared early in the course of treatment, often within the first few weeks.

Estrogens.—The most prominent side-effects produced by estrogen therapy were pigmentation of the areola and axilla, edema, and vaginal bleeding. Nausea, vomiting, and incontinence usually were disturbances of a secondary order of importance in both their incidence and their degree of discomfort.

Pigmentation of the areola and axilla was observed in 31 and 23%, respectively, of the patients treated with estrogens. Pigmentation of the areola is much less noticeable in Negro women. In contrast to the frequency of pigmentation of the areola and axilla, gross enlargement of the uninvolved breast was infrequent. Vaginal bleeding occurred in 22% of postmenopausal patients receiving estrogens. The uterine flow was usually minimal (consisting of staining or spotting), and therapy could often be continued without interruption. Occasionally, however, bleeding was sufficient to require curettage or modification of the prescribed dose. Withdrawal bleeding occurring 5 to 10 days after the cessation of therapy was noted particularly in elderly women. This usually lasted no longer than one to two weeks. Vaginal bleeding associated with androgen therapy was a rare occurrence but was present in 2% of the patients.

Urinary incontinence, usually of the stress type, occurred in 17% of the patients treated with estrogens. Although this sign was usually mild, it often proved embarrassing to elderly women. Nausea, occasionally associated with malaise, anorexia, and vomiting, was the commonest gastrointestinal side-effect observed. Administration of the hormone between meals, as well as a gradual increase in the dose schedule, usually permitted full tolerance of the drug despite these disagreeable effects.

Both androgens and estrogens are known to produce an increased retention of sodium and a corresponding increase in extracellular fluid. Edema was noted in 26% of the patients receiving androgens and in 24% of those receiving estrogens. However, there were many patients (particularly among those receiving testosterone) who gained 5 to 15 lb. (2.3 to 6.8 kg.) in weight without gross evidence of ankle edema. It is difficult but important to attempt to differentiate the water-retaining effect from the anabolic effect when evaluating weight gain in the patients treated with androgens. It is well known that an individual can gain up to 10 to 12 lb. (4.5 to 5.4 kg.) in edema fluid before clinical evidence becomes apparent. In the patient with a previously compromised cardiovascular system, this increase in extracellular fluid may precipitate or hasten decompensation.

Kennedy and Nathanson have reported that "in 17 patients (9 per cent) of those receiving estrogen therapy, fluid retention led to congestive cardiac failure or exaggerated an existing mild decompensation." Any additional cardiovascular strain in older patients may precipitate cardiac decompensation. Patients with known cardiac disease should be given hormones with great caution. Also, postmastectomy lymphedema can frequently be aggravated during hormone therapy. Although salt and fluid retention can be a serious complication of hormone therapy, particularly in patients with cardiovascular disease, simple measures may be undertaken to minimize this contingency. A low-salt diet and rigid fluid restriction in addition to diuretics and digitalis when indicated may allow patients to continue hormone therapy without interruption.

Table 4.—*Comparison of Side-Effects of Ethinyl Estradiol and Chlorotrianisene (TACE)*

	Ethinyl Estradiol (50 Cases)		Chlorotrianisene (41 Cases)	
Side-Effect	No	%	No.	%
Edema	10	20	9	22
Bleeding	5	10	13	32
Flushing	4	8	4	10
Nausea	6	12	10	24
Vomiting	3	6	4	10
Loss of hair	7	14	5	12
Pigmentation of areola	22	44	9	22
Pigmentation of axilla	14	28	4	10
Incontinence	7	14	6	15

Hypercalcemia is an infrequent but serious side-effect, occurring in 5% of the patients receiving androgens and in 1% of those receiving estrogens in the present series. However, it has been reported more frequently by the Committee on Research, occurring in 7.7% of patients treated with estrogens and in 14.2% of those treated with androgens. Clinical evidence of hypercalcemia is manifested by anorexia, nausea, vomiting, and weakness, which in severe cases may go on to disorientation, stupor, and coma. Initial symptoms may be deceptively mild, but the syndrome may progress rapidly to a hypercalcemic crisis, renal failure, and death. The syndrome of hypercalcemia may be difficult to rectify, but immediate cessation of therapy is always mandatory. Supportive therapy, consisting of a low-calcium diet and infusions of saline solution, dextrose, and a 2.5% solution of sodium citrate, often proves helpful. Pearson, West, and Hollander [12] have reported that cortisone has been used very successfully in several cases of hypercalcemia. The effectiveness of this drug has been amply confirmed by others. The subsidence of hypercalcemia and hypercalciuria was associated with prompt clinical improvement.

Laszlo and his co-workers [13] have studied the mineral metabolism of patients with bone metastases and have not infrequently found elevated levels of urinary calcium and phosphorus excretion even without hormone treatment. When the amount of calcium created by osteolysis due to tumor invasion exceeds the amount that the kidney can excrete, hypercalcemia results. Thus, hypercalcemia may occur spontaneously in patients with osseous metastases as well as in those with the more serious hormone-induced syndrome. In the current study, hypercalcemia was defined as any calcium level in excess of 12 mg. per 100 cc. of blood. None of the patients in the present series who showed evidence of elevated blood calcium levels had clinical symptoms of hypercalcemia. Perhaps the low incidence of serious hypercalcemia can be attributed to the predominance of ambulatory patients such as are seen in a clinic. In bedridden patients with metastases who are immobilized over a long period of time, osteoporosis and disuse may excessively elevate the calcium level.

Comparison of the various estrogens and androgens used in this study failed to reveal any striking difference in the incidence of their side-effects. However, in the specific comparison of side-effects caused by ethinyl estradiol and chlorotrianisene, some significant differences are shown in table 4. A statistically valid variation occurred in the frequency of vaginal bleeding (10% for ethinyl estradiol as compared with 32% for chlorotrianisene) and in the incidence of pigmentation changes. The side-effects of stanolone when compared with those of testosterone showed all of the predominant androgenic characteristics except a lower incidence of increased libido. The number of patients showing side-effects due to combined estrogen-androgen therapy was not sufficient for critical evaluation. However, the specific changes caused by individual sex steroids may be masked or minimized by combined treatment.

Combined Androgen-Estrogen Therapy

There were eight patients who received complete courses of ethinyl estradiol (3 mg. daily) plus testosterone propionate (100 mg. three times weekly) simultaneously. The results of this combined treatment are shown in table 5. A critical analysis of this small sample is, of course, unwarranted, but there would appear to be no striking superiority in either the objective or subjective response over that of similar treatment with either hormone alone.

Survival

Although there is little doubt that the sex steroids are effective in the palliative treatment of advanced cancer of the breast, it would be of equal importance to know whether this type of therapy actually prolongs survival time. However, the unequivocal answer to this problem remains to be solved. One must be extremely cautious in selecting "comparable series" for this type of a statistical study, as it is readily apparent that the degree of advancement of the disease is difficult to determine and the heterogeneous composition of these preterminal groups is so conspicuous. Despite this question of validity of comparison among dissimilar series, the Committee on Research states that steroid therapy "may prolong life" as demonstrated by the following figures taken from their Second Conference on Steroids and Cancer[10]: 347 patients with soft-tissue involvement were treated. The average survival rate for the patients whose conditions were not improved was 7.5 months, while, for the 100 patients who showed tumor regression for an average period of 6.1 months, the survival rate averaged 13.57 months. Thus, patients who responded to treatment lived twice as long as those who failed to respond.

Hallberg, Nohrman, and Sylven[14] compared the mean survival time in two series of patients, taking time zero as the date of diagnosis of bone metastases. Patients with visceral lesions were excluded from the study, but patients with soft-tissue metastases were included. One series of 97 patients was treated with testosterone alone, and a control series of 254 similar patients was treated by palliative radiotherapy. The mean survival time for the patients treated with androgens was 21 months, as compared with 15 months for the controls. Hallberg, Nohrman, and Sylven conclude that "the data suggest that androgen treatment significantly increases the length of survival."

Huseby[15] has recently presented a comparison in longevity between a group of 58 patients in Minnesota with "generalized" metastases treated with estrogens from 1946 to 1951 and a seemingly similar group of 193 patients in California treated palliatively (without hormones) by Shimkin and his colleagues from 1918 to 1947.[16] The mean and median survival times were 10 and 7.8 months, respectively, for Shimkin's group and 20.3 and 16 months, respectively, for Huseby's group. Huseby found by analysis that the difference in survival time between patients in these two series was statistically highly significant.

Thirty-one patients in the present series with advanced disease were treated with the sex steroids only from the time of diagnosis until death or until they were lost to further follow-up. Also, seven of these patients are still alive and are receiving treatment at the present time. Results of a life table were found to be difficult to evaluate critically because of the small number of patients in the study and the large number of withdrawals. Those patients withdrawn from observation tend to increase the uncertainty of the estimate (and therefore increase the standard error). However, the three-year survival from the time of diagnosis of advanced or metastatic breast cancer was 24%, with a very large standard error of ± 18.6%. It is hoped that homogeneous series similarly treated (with and without hormones) will be reported by other investigators so that survivorship and prolongation of life may be more accurately compared. It is to be noted that a statistically valid conclusion as to whether life is lengthened in these patients treated with hormones can be made only when their survival is compared with that of a group of completely untreated patients. However, in this age of modern surgery, radiotherapy, castration, adrenocorticoid therapy, and other chemotherapeutic adjuvants, it is doubtful that such a series of untreated cases will ever again be found. Older series were found to be deficient in several respects, thus invalidating comparison.

Comment

It is to be pointed out that the individual groups of patients receiving androgen and estrogen therapy were not entirely comparable by virtue of some difference in their age range. Androgen therapy was used in both premenopausal and postmenopausal patients, whereas estrogen therapy was used only in postmenopausal patients. Despite some conflict in the medical literature,[17] cancer of the breast in young premenopausal women appears to be a more menacing disease. Therefore, one may be permitted to question the validity of the relatively poor results of androgen therapy in a group of younger premenopausal women in whom the prognosis is known to be less favorable. Present experience confirms the well-known fact that the relentless growth of mammary cancer can be modified and even caused to regress by appropriate alterations in the hormonal environment. However, despite even the most spectacular remission after a change in the endocrine milieu, the disease ultimately progresses by adapting itself to its new environment. Thus, since hormone therapy for advanced mammary cancer is time-limited and unpredictable in its palliative effectiveness, it should be used only after more definitive measures of treatment such as surgery and radiotherapy are no longer applicable. The duration of objective remission under hormone therapy was highly variable in point of time, lasting from a few months to an indefinite period of years. In the exceptional instances of long-lasting benefit, we tend to celebrate our successes without proper regard for the degree of host resistance—an unknown factor of the utmost importance.

In addition to sex steroid therapy, a variety of endocrine procedures designed to alter the hormonal environment have been known to induce a temporary remission in patients with advanced mammary cancer. Such operations for endocrine ablation as oophorectomy, adrenalectomy, and hypophysectomy have been used beneficially in the palliative treatment of this disease. Cortisone and its derivatives, with or without thyroid medication,[18] have been used with some success, particularly in patients with metastases to the brain. However, it is not the purpose of this paper to review these several modalities of endocrine ablation or to discuss their role in the total treatment of this disease. Whereas interruption of ovarian function is most successful in young women with advanced mammary cancer and the administration of the estrogens is of greatest benefit in elderly women, in androgen therapy the age of the patient appears to be of relatively little importance. A notable effort is being made in biochemical research to discover newer sex steroids that, on the one hand, will have an even greater potency of tumor suppression and, on the other, will have an even lower incidence of undesirable side-effects. Thus far, however, there appears to be no androgen possessing positive superiority over testosterone and no estrogen to excel either ethinyl estradiol or diethylstilbestrol. The degree of response to therapeutic doses as compared to massive doses of the same drug remains to be clarified.

Summary and Conclusions

One hundred thirty-three patients received 223 complete courses of sex hormone therapy for advanced mammary cancer. The choice between estrogen and androgen was made principally in relation to the physiological age of the patient in reference to her menopause. Estrogens were used only after five years had passed since the menopause, whereas androgens were found to be useful in both premenopausal and postmenopausal patients. However, in the definitely older patients, estrogen appeared to be the hormone of choice.

A favorable objective response occurred with estrogen therapy in 40% of patients with primary tumors, 31% with soft-tissue lesions, 32% with visceral lesions, and only 17% with osseous lesions. Both stilbestrol and ethinyl estradiol were found to be superior to chlorotrianisene (TACE) in estrogen therapy. A favorable objective response occurred with androgens in 27% of patients with primary tumors, 23% with soft-tissue lesions, 15% with visceral lesions, and only 11% with osseous lesions. There appeared to be no significant difference in objective therapeutic effectiveness between the several androgens used. The optimum dose of testosterone propionate was 50 to 100 mg., given intramuscularly three times weekly. Complete or partial relief of pain occurred in 52% of the patients treated with androgens and in 51% of those treated with estrogens. Stanolone appeared to be superior to testosterone propionate in the subjective relief of pain. A sense of well-being occurred in 48% of the patients treated with androgens and in 44% of those treated with estrogens.

Although the sex hormones are certainly not a "cure" for advanced mammary cancer, in the total care of this disease they do offer profound and gratifying benefits for patients beyond the scope of surgery and radiotherapy. Whereas "severity is allowable when gentleness is in vain," it has been our practice to make full use of the initial palliative benefits of hormone therapy before considering the more drastic operative procedures such as adrenalectomy or hypophysectomy.

Acne Vulgaris.—The main aim of therapy in acne vulgaris is to remove the blockage from the mouth of the pilosebaceous follicles, thereby allowing the retained sebum to escape on to the surface of the skin, and to decrease the size and activity of the sebaceous glands. This aim could be realized quite simply by giving suitable amounts of estrogens, were it not that the dose necessary would cause feminization in males and uterine bleeding in females. To a certain extent, however, it is possible to produce similar results by different means. . . . Soap and water attain therapeutic qualities in local treatment, especially when the skin is greasy and comedones are plentiful. The face should be washed four or five times a day in hot water and then briskly rubbed with a soft towel. The exact type of soap is unimportant, but the addition of borax or sodium bicarbonate to the water is helpful. Sulphur is the most useful local application, as it causes an exfoliation of the surface layers of the epidermis, thus removing the comedones. To maintain a mild peeling of the skin should therefore be the aim of treatment. The sulphur can be incorporated in a lotion, emulsion or paste. Care must be taken not to cause too drastic a reaction and this is especially likely to occur in fair-skinned individuals. Two or four per cent of sulphur is a reasonable strength with which to begin and this may be slowly increased up to ten or twelve per cent.—P. F. Borrie, M.D., M.R.C.P., Acne Vulgaris, *The Practitioner*, May, 1956.

SORTING—THE KEY TO MANAGEMENT OF VICTIMS OF DISASTER

Lieut. Col. H. Haskell Ziperman (MC), U. S. Army

• *The simultaneous infliction of injuries of all degrees on a large population must be anticipated in the event of either natural or nuclear disasters. When facilities for treatment are limited, the greatest possible number of lives can be saved only by making sure that these facilities are not exhausted by injudicious use on either the trivial or the hopeless cases. Triage, the sorting of the injured, must be done by the most mature surgeon available. It decides questions of treatment, of transportation, and of return to duty. Its effectiveness is enhanced by attention to the changing tactical situation. The principles of triage here stated were developed under conditions of conventional warfare. But it must be assumed that with certain modifications they will apply also under the altered conditions of the future, such as the sudden outbreak of nuclear warfare or the occurrence of natural disasters in a more densely populated world.*

The medical management of large numbers of sick or injured, whether they result from epidemic disease, combat, or disaster, involves the establishment of an organization that takes into consideration every essential of proper care. This orderly process of medical management insures that wherever possible each patient will receive treatment in proportion to his degree of morbidity and disability and under no circumstances will the lives of the many be jeopardized by the medical needs of the one or of the few. In order to function properly, this organization must be prepared to classify and categorize its patients on the basis of type and severity of wound or disease condition so that a minimal time loss in the institution of proper therapy and disposition of each case can be expected. Early classification permits visualization of over-all medical requirements for large groups of casualties and, on this basis, aids in the decision as to when, where, and what type of therapy should be instituted. Lack of early classification of the sick and wounded en masse leads to confusion, chaos, and increased mortality, for then each patient is individually treated without regard for the more urgent needs of others in the group or for the medical capabilities of the organization.

Sorting, or triage, is officially defined by the U. S. Army as the procedure by means of which the sick and wounded are classified according to type and urgency of condition presented, so that they can be properly routed to medical installations appropriately situated and equipped for their care. It is a procedure that had its inception in the care of those wounded in combat but that, with only minor modification of specific detail, may be equally as well applied to any organization having as its responsibility the care of large numbers of injured generated relatively simultaneously. Sorting is, in fact, the key to the management of these patients, for it is only by its means that casualties may be categorized properly and separated so that there will be a minimal time lag between injury and the onset of therapy. In its application, sorting considers the necessity for overlooking no one and for doing the greatest good for the largest number of casualties. Both these goals are accomplished by taking into consideration the medical capabilities of the installations involved and the relative proportion between the number of professional personnel available for the institution of therapy and the total number of patients requiring treatment.

Decisive Factors in Sorting

Sorting is directed toward making decisions with regard to, first, the establishment of criteria for the return of the injured to duty. In combat, this decision will vary with both the type of wound sustained and the specific tactical situation, so that under no circumstance will a casualty be returned to duty if his incapacitation might interfere with the conduct of the battle. Conversely, no casualty will be unduly delayed in his return to duty, for delay would result in the need for a replacement, and it is uneconomical to replace a battle-tried veteran with an unseasoned soldier. It thus becomes necessary to hold and treat casualties for periods of time that vary according to type and severity of wound, for upon return to duty these casualties must be assets rather than liabilities to their organization. In this way, a priority for return to duty is established by weighing clinical condition against tactical requirements. In a disaster, on the other hand, clinical condition must be weighed against manpower shortages. Thus, the size of the disaster and the availability of outside help for the institution of rescue and of first-aid and emergency medical treatment may determine what type of injured, and how many, must be released in order to aid in the care of the other victims. Early release of disaster victims may also be determined on the basis of available hospitalization facilities, so that overcrowding and consequent jeopardy to health may be minimized.

The second decision to be arrived at in sorting concerns the establishment of priority for treatment. Because the type and urgency of the therapy to be employed will vary with the severity of the wound, a priority must be established for the care of the various types of wounded. Treatment priorities are not only dependent on the urgency of therapy required but also vary with the stated function of a particular installation, for it is on this basis that specially trained medical personnel are assigned and supplies and equipment allocated. Thus, the treatment to be given must be within the medical capabilities of the particular installation. With an adequate number and type of assigned professional personnel, priorities for treatment may have to be varied by the type and availability of medical supplies and equipment. Typi-

cally, a hospital with only a limited supply of blood on hand and with little likelihood of more becoming available in the near future will spread the use of that blood so as to aid in the recovery of the largest number of injured. On this basis, the critically wounded man who would require all of the only 10 units of blood available in order to aid in his possible recovery would drop in priority to a position below that of the five casualties whose certain recovery would be insured by the receipt of 2 units each. Conversely, where only 2 units of blood are on hand to treat the shock of 10 casualties, the best utilization of this item would entail using it in the resuscitation of no more than 1 or 2 of these casualties rather than wasting it by giving each only 1/5 unit.

Establishment of priority for treatment may also be varied by the number and caliber of physicians available for the institution of treatment. Thus, in a disaster zone in which all physicians have become disabled and the institution of therapy must be accomplished by ancillary medical personnel, such as dentists, veterinarians, and nurses, little would be accomplished by the establishment of priorities for surgical procedures of other than minor magnitude, for they would be beyond the capabilities of the available personnel. In such a situation, only priorities for resuscitation and emergency medical treatment would be instituted. These casualties would then be evacuated to other installations whose personnel are more capable of handling the complicated technical surgical procedures required. Where large supplies of medical matériel are immediately available, in an installation adequately staffed for the care of any casualty, the priority for surgical treatment will depend on the type and urgency of treatment required.

The third type of decision to be rendered is the casualty's need to be evacuated for further treatment and the timing of this move in relation to the program of therapy. Basically, requirements for evacuation are determined by the need to conform to the tactical situation, which limits the number of noncombat personnel and matériel brought into a combat zone. This limitation is necessary to prevent excessive interference with the mobility and maneuvering of the tactical force and allows for only a few small, highly mobile medical installations in the area. The evacuation of casualties either to prevent their interfering with the conduct of the battle or in order to insure them more adequate treatment in the larger, less mobile, better-equipped installations farther to the rear is, therefore, necessary. Obviously, evacuation should be performed only for those casualties whose physical deterioration will not be accelerated by it and should be carried out in such a manner that safeguards will be provided against such an eventuality. Thus, a system of priorities for evacuation is established in the determination of which physical condition is weighed against the rigors of travel and both are balanced against the available means for transportation.

Although in some instances the priority for evacuation is the same as the priority for treatment, frequently the necessity for early urgent therapy is of such a high degree that unwise early evacuation prior to treatment could result in death. For example, a casualty in severe shock as the result of uncontrolled bleeding from a laceration of the femoral artery enjoys a high priority for the control of his bleeding and the treatment of shock and no priority for evacuation. After necessary resuscitation has been performed, he then receives a high priority for evacuation so that vascular surgery may be performed early. Each surgeon, as he sorts to determine priority for evacuation, must assess the urgency and degree of essential medical care against the available means of evacuation and the supporting medical capabilities. He must avoid arbitrary sorting for evacuation by determining that there is a place to which casualties can be evacuated, that there are suitable means for evacuation, and that the patient is in a fit state for this evacuation. All these factors will vary with the particular situation, and sorting must, under all conditions, be permitted to remain flexible.

Other Considerations

All sorting, since it requires a high degree of professional skill in making the requisite clinical judgments, should be performed by the most mature surgeon of a given installation. These decisions are based on clinical experience plus an expert knowledge not only of the particular tactical situation but also of the medical capabilities of all installations in the treatment chain. A realistic appraisal must be made regarding the likelihood of survival, the time required to perform the needed technical procedures, and the capabilities for medical care available at the time and place. Errors in judgment will lead to increases in morbidity and mortality through submitting to surgery casualties who have not been adequately resuscitated, evacuating injured without regard to clinical condition or the rigors of movement, and attempting procedures beyond the capabilities of the installation.

Sorting is a continuous procedure that starts with initial medical care and terminates only with the final disposition of each patient. It must establish priorities at each installation in the treatment chain because the function, medical capabilities, and facilities of each are different, and due consideration, in the light of these factors, must be given to every casualty upon his arrival in the installation. Moreover, the condition of the patient will change as a result of the institution of resuscitative treatment, necessitating re-sorting. Furthermore, a continuing influx of casualties may cause a change in the priority for treatment and evacuation of the injured already present. These changes produce the need not only for sorting at each installation but also for a revision of priorities at fairly frequent intervals in each.

In addition to all of the foregoing factors, or perhaps because of them, sorting is necessarily a flexible procedure, for the considerations influencing the required decisions will vary from day to day and from one situation to another. Typically, the surgeon who sorts by rote may fail to consider many factors important in making the proper decisions. For example, he might overlook the fact that a disparity between the number of wounded and the total number of personnel available for institution of therapy might require a larger number of early evacuations to less crowded installations. If he fails to consider the need to move his installation in keeping with the tide of battle, he may accept more casualties than he can treat in the time allotted prior to the move. If, in his sorting for evacuation, he fails to consider inclement weather as a deterrent to helicopter travel, he may bring about increased mortality by subjecting casualties to traumatic overland ambulance hauls. The ever-changing tactical situation must be observed and sorting remain flexible and subject to modification as needed.

As enunciated in the preceding paragraphs, sorting has as its objective the classification and separation of large numbers of sick and wounded so that priorities for treatment, evacuation, and return to duty may be more easily established. This system has evolved by trial and error through past wars until at the present time we pride ourselves on the fact that by its means no casualty is ever denied treatment. Treatment is usually commensurate with the severity of injury and the quality and number of facilities and personnel available; the time lag between wounding and the institution of therapy is reduced to a minimum; and, because of its efficiency, we accomplish the greatest good for the largest number. Remember, however, that this concept of the establishment of priorities was developed during conventional warfare and was based on an unfailing source of medical supplies and little or no disproportion between numbers of casualties and quantity and quality of medical personnel available for treatment. In practice, this system has resulted in priorities for treatment usually being established on the basis of wound severity, so that the most severely wounded enjoy the highest and the least severely wounded the lowest priority.

Priority System for Nuclear Warfare

Prior planning for the surgical care of mass casualties resulting from nuclear warfare, where limited treatment facilities, inadequate supplies, and a shortage of medical personnel will prevail, makes it evident that, in order to provide no disservice to the many in favor of the few, some modification of our priority system must be established. Such a modification, as outlined in a Department of the Army technical bulletin[1] provides, in the event of atomic disaster, for all injured to be divided into four groups:

1. Casualties requiring minimal treatment:
   a. Those who may return to duty after minimal treatment is given.
      (1) Those with small lacerations or contusions.
      (2) Those with simple fractures of small bones.
      (3) Those with second degree burns of less than 10% of body surface and not involving incapacitating burns of face or hands.
   b. Noneffectives who require domiciliary or nursing care after minimal treatment is given.
      (1) Those with disabling minor fractures.
      (2) Those with burns of the face or hands of less than 10% extent but which interfere with the individual's ability to care for or feed himself.
      (3) Those with moderate neuropsychiatric disorders.
2. Casualties requiring immediate care:
   a. Those with hemorrhage from an easily accessible site.
   b. Those with rapidly correctable mechanical respiratory defects.
   c. Those with severe crushing wounds of the extremities.
   d. Those with incomplete amputations.
   e. Those with severe lacerations involving open fractures of major bones.
3. Casualties whose surgical treatment may be delayed without immediate jeopardy to life:
   a. Those with closed fractures of major bones.
   b. Those with moderate lacerations without extensive bleeding.
   c. Those with second degree burns of less than 30% and third degree burns of less than 20% of the body surface.
   d. Those with noncritical central nervous system injuries.
4. Casualties whose therapy will be expectant:
   a. Those with critical injuries of the central nervous system or respiratory system.
   b. Those with significant penetrating or perforating abdominal wounds.
   c. Those with multiple severe injuries critical in nature.
   d. Those with severe burns of large areas (second or third degree burns of 40% or more of the body surface).

It is estimated that in atomic disaster group 1, those requiring minimal treatment, will comprise approximately 40% of the total casualties. These casualties truly have no priority for treatment but in practice will receive their treatment early. Ordinarily, their wounds are of such a nature that the treatment they receive while being sorted is all the therapy that they require, and they can then be returned to duty or remanded to domiciliary care.

Group 2, those requiring immediate care, is expected to comprise 20% of the total number of casualties. These injured will enjoy the highest priority for surgical treatment because a relatively short procedure will suffice to save life. Further, more definitive surgery for these casualties can then be delayed, although the possibility of infection must be accepted as the price of this delay.

Group 3 is expected to comprise 20% of the total and is composed of casualties a delay in whose surgical treatment will probably lead to infection but whose lives will not be jeopardized by the delay. The time lag between wounding and surgery for this group will be dependent on the total number of casualties of all types and the number of professional personnel available to institute surgical treatment.

Group 4 is expected to comprise 20% of all casualties resulting from the explosion of a nuclear weapon. Their expectant treatment will not be one of masterful neglect but instead will consist of that resuscitation and emergency medical treatment that the available facilities, total supplies, and number of professional personnel permits. Theirs will, however, be the lowest priority for treatment, because both the operative procedures and the resuscitative measures required are lengthy and technically complicated, so that the institution of therapy for one of these casualties would theoretically jeopardize the lives of several casualties in other priority groups. Increased loss of life in this group is accepted as a necessary consequence of this low priority for surgery.

Summary

Sorting is the key to the management of large numbers of injured generated during conventional comba for it is only through its utilization that modern pri ciples and practices of therapy may be proportionate applied to the combat wounded. Provided the enumerated changes in priorities are established, it will also become the key to the care of the larger number of simultaneously generated casualties resulting from the use of nuclear weapons in warfare. In civilian disasters or epidemics, adherence to the principles of sorting, establishment of priorities, and, where applicable, the need for evacuation will aid in minimizing morbidity and mortality.

Sorting is the procedure by means of which the sick and wounded are classified according to type and urgency of condition presented, so that they can be properly routed to medical installations appropriately situated and equipped for their care. It is a continuous procedure throughout the treatment chain and is practiced in each installation by the most mature surgeon available. The effectiveness of sorting is enhanced by observation of variations in the tactical situation. Sorting is directed toward establishing criteria for return to duty and priorities for treatment and evacuation. With certain changes in priorities, sorting as practiced during conventional warfare may be applied as the key to the management of casualties caused by either natural or nuclear disasters.

THE DETERMINATION AND CLINICAL VALUE OF UROPEPSINOGEN

William P. Peak, M.D., Ellenmae Viergiver, Ph.D., Edward J. Van Loon, Ph.D.
and
Garfield G. Duncan, M.D., Philadelphia

- *Determination of the concentration of pepsinogen in the urine can be technically practical and clinically useful. It may offer a better index of gastric peptic activity than does intubation, and it has been useful in the differential diagnosis of peptic ulcer versus gastric carcinoma. Uropepsinogen values can aid in locating the site of hematemesis and can assist in the diagnosis of pernicious anemia. The response of uropepsinogen to hormone stimulation may provide many diagnostic, as well as therapeutic, indexes to endocrinological conditions.*

Although 49 papers dealing with the subject of pepsinogen in the urine have been published since Bucher's[1] comprehensive review in 1947, there still exists a controversy as to its clinical usefulness. Much of the debate, so well described by Bridgewater,[2] is due to criticism of methodology rather than of clinical results. Most of the adverse criticism comes from those who employ the Anson and Mirsky tyrosine method[3] of determining the quantitative concentration of uropepsin in the urine. This procedure is cumbersome. It is full of potential pitfalls, is expensive, and requires a highly trained technician if the results are to be relied upon. In contradistinction, those who have utilized the simpler method herein presented have in the main concurred with us that the determination is both technically practical and clinically useful. The patient may follow his usual routine, no fasting or withholding of medication being necessary. Since, as Spiro[4] has indicated, uropepsinogen values may offer a better index of gastric peptic activity than those analyses in which gastric intubation is routinely required, their determination has considerable clinical promise. Furthermore, the simplified method employed is applicable in those hospitals not equipped to carry out highly technical procedures.

Many authors have recognized the value of uropepsinogen in considering differential diagnoses.[5] It has proved useful in the diagnosis of gastrointestinal disease, notably peptic ulcer and gastric carcinoma. In macrocytic anemias, associated with an achlorhydria not altered by stimulation with histamine, it is a reliable differential test in excluding pernicious anemia.[6] In cases of massive hematemesis, uropepsinogen values have been useful in the consideration of the differential diagnoses. Low levels have been consistently found in bleeding esophageal varices, whereas in cases of bleeding duodenal ulcers the values are consistently high. Early in the hospital course when gastric analysis may not be feasible, a simple quantitative test of the urine for uropepsinogen may be of critical value.

An apparent relationship between the level of uropepsinogen and the state of activity of the adrenal cortex has been noted.[7] In Gray's study[5a] "there was noted a marked diminution in excretion [of uropepsinogen] in patients with panhypopituitarism and Addison's disease and a definite increase in the excretion in patients with Cushing's disease, accompanied by parallel alterations in corticoid and ketosteroid excretion." Replacement therapy in both groups was manifest in the uropepsinogen's stabilization at normal concentrations. It has been postulated that the uropepsinogen response to hormone stimulation may be an index of gastric hypersecretion in patients undergoing prolonged treatment with cortisone or corticotropin. The presence of a high output might herald impending complications of hormone therapy, notably, the development of a duodenal ulcer, hemorrhage, or perforation. Boland[8] has demonstrated that this aspect is becoming increasingly important in this steroid era. Thorn[9] and others[10] have verified the work of Garst

Fellow, National Institute of Arthritis and Metabolic Diseases (Dr. Peak); Chemist to the Pennsylvania *Hospital (Dr. Viergiver)*; Assistant Section Head, Biochemistry, Smith, Kline & French Laboratories (Dr. Van Loon); and Director of the medical divisions of the Pennsylvania Hospital and the Benjamin Franklin Clinic (Dr. Duncan). Dr. Peak is now *in Louisville*, Ky.

and Hilliard [11] demonstrating the relationship between uropeptic activity and the state of the pituitary-adrenal axis. The clinical practicality of a simple determination of the concentration of uropepsinogen in a specimen of urine is apparent.

Physiological Considerations

Mirsky and his co-workers [12] verified the work of earlier investigators by establishing two facts: The source of uropepsinogen is the stomach, and it reaches the urine in some other way than by resorption from the intestine. If this be true, then an animal that had undergone total gastrectomy would have no pepsinogen in the urine. This has been shown repeatedly to be true in a variety of animals and in man. It was also concluded that since pepsin is inactivated at a pH of 4 and since blood is of a pH range 7.35-7.45, the pepsin-like substance in the urine must indeed be its precursor or zymogen—pepsinogen. Pepsinogen is stable at the pH of blood.

TABLE 1.—*Uropepsinogen Values in Normal Subjects and in Patients with Duodenal Ulcer*

Type of Subject	No. of Subjects	Uropepsinogen (Range), Mcg./Hr.	Uropepsinogen (Mean), Mcg./Hr.
Normal*	19	20.5—188.7	77.5
Duodenal ulcer	13	115.4—967.5	328.0

* Technicians and doctors on the laboratory staff with no symptoms of hematological, gastroenterological, or endocrine disorder.

These experiments indicate that the peptic gland is both an exocrine and endocrine organ. Janowitz and Hollander [13] have found a definite relationship between the exocrine and endocrine function as regards pepsinogen, this relationship being 99:1 (exocrine to endocrine). These results offer a sound basis for the consideration of the utility of a test for uropepsinogen in the detection of gastric peptic activity.

Experimental Procedure

Urine samples are collected in bottles containing 0.5 cc. of sulfuric acid (25%) to insure constant acidity. Pepsinogen in the urine is converted to pepsin by incubating a portion of the sample for one hour at 37 C with 2 *N* hydrochloric acid. A pH of 2.5 to 3.0 is necessary to obtain conversion. Buffered casein solution is added to an aliquot of the activated urine and the time required for the pepsin to flocculate casein particles is observed. This is the Goodman modification [6a] of the original West method [7a] referred to above as the "simpler" technique.

TABLE 2.—*Effect of Surgery on Uropepsinogen Values*

Reason for Operation	No. of Subjects	Mean Uropepsinogen, Mcg./Hr. Preoperative	Mean Uropepsinogen, Mcg./Hr. Postoperative	Type of Surgery
Duodenal ulcer	1	261.9	305.1	Vagotomy
Lesser curvature gastric ulcer	1	37 8	13.5	Subtotal gastric resection

Since the uropepsin assay is based upon comparison with crystalline pepsin, it was decided to express results in terms of micrograms of pepsin rather than arbitrarily defined units. Dilute solutions containing 0.05-0.30 mcg. of crystallized pepsin per 0.1 ml. are treated in the same manner with water, buffer, and substrate as the activated urine. The stock solution of pepsin (25.0 mg. in 250 ml. of dilute hydrochloric acid) keeps at least two months when refrigerated. The values for the pepsin solutions are plotted on log-log graph paper, and the urine values are calculated from it. The amount of pepsin per aliquot of activated urine is converted to micrograms per milliliter of urine. This figure is then multiplied by the total volume of the specimen divided by the four hours of collection, thusly: mcg. per ml. × vol./4 = mcg. per hour. Results obtained by two different technicians agree within 0.01 to 0.07 mcg. per 0.1 ml. (In order to facilitate comparison of our results with those of authors who have employed the arbitrary West "units," the reader may divide the micrograms per hour by 2.7). Each technician should construct his own standard curve daily in order to eliminate possible variations in the detection of the end-point by different technicians and to eliminate possible variations in different casein substrates. This is much the same as a prothrombin "control" in the routine laboratory procedure.

Since uropepsinogen is stable for days when kept at a suitable temperature in a refrigerator, in an emergency during weekends, a preoperative urine specimen could be obtained and stored until the laboratory staff resumes activities. For surgical follow-up studies, this affords a feature not present in many laboratory tests.

TABLE 3.—*Hematological Value of Uropepsinogen Determination*

Disease	No. of Cases	Uropepsinogen (Range), Mcg./Hr.	Uropepsinogen (Av.), Mcg./Hr.
Proved pernicious anemia	2	0.7—2.2	1.4
Suspected pernicious anemia (macrocytic anemia with histamine achlorhydria)	4	28.0—117.5	61.6

Results of Study

The results presented were obtained from a series of 57 cases. Since the compilation of these data, additional cases have been tested, and a cursory examination of the results reveals confirmatory evidence for the facts herein presented.

Table 1 depicts the difference between the normal value of uropepsinogen and those encountered in subjects with duodenal ulcers. Though the normal range overlaps those values found in the presence of the cases of duodenal ulcers, it should be pointed out that 92% of the patients with duodenal ulcers had higher values than the highest normal. Of the overlap group, 79% were greater than three times the mean normal. A thorough appraisal of this lower bracket revealed that each patient was on a strict ulcer therapy regimen at the time of the test, and none of these had an actual ulcer niche demonstrated roentgenographically. This influence of activity on the level of uropepsinogen has been noted by others.[14]

Table 2 [15] illustrates the value of uropepsinogen determinations in assessing the results of surgery. It might appear that vagotomy is a worthless procedure because it did not reduce the uropepsinogen content of the urine. This is not necessarily so; this finding merely indicates that at least the hormonal relationship still exists despite surgery. In the second case (table 2), despite the initial low level the uropepsinogen is reduced by approximately 65% postoperatively. Our findings agree with those of the Boston group where 26 such patients were studied.[5a]

As can be seen in this illustrative case of gastric ulcer, the level of uropepsinogen, falling within the normal range, is not diagnostic. This was true in three other cases, in which the range was 81.9 to 84.5, with a mean of 83.2 mcg. per hour. Uropepsinogen levels in cases of gastric malignancy, on the other hand, have been found by Gray[5a] to be considerably lower than those in patients with benign gastric ulcers. This was true in 61% of 53 patients with carcinoma, the level being zero in four cases of linitis plastica. In only three cases of malignancy in our series was the range 37.5 to 150.0 mcg. per hour. In these three examples, it can be seen that the uropepsinogen would have been of no diagnostic significance. It should be stated, however, that Gray's statistics correlate well with the well-documented higher incidence of carcinoma in hypofunctioning stomachs.

Table 4.—*Uropepsinogen Excretion Values in Various Disorders*

Case No	Suspected Diagnosis	X-Ray and Laboratory	Uropepsinogen, Mcg./Hr.	Final Diagnosis
1	Upper G.I. hemorrhage, probably marginal ulcer, dumping syndrome	G.I series negative; submucosal rectal carcinoma (by biopsy)	41.4	Submucosal rectal carcinoma
2	Surgical abdomen, etiology probable perforated duodenal ulcer	Serum amylase 448 units	133.9	Pancreatitis
3	Pituitary adenoma, previously diagnosed, now in remission	Eroded sella; 17-ketosteroids, B.P., and blood sugar normal	158.4	Same as suspected*
4	*Pituitary myxedema*	I [131] uptake 2.7; 17-ketosteroids (low), Kepler-power positive	7.8	Same as suspected
5	Laennec's cirrhosis, upper G.I. hemorrhage from probable peptic ulcer or esophageal varicosity	Prothrombin 29%, BSP (elevated), cephalin flocculation 4, bilirubin (elevated), albumin 1.7, globulin 7.0; G.I. series negative	73.0	Hypoprothrombinemia bleeding due to Laennec's cirrhosis
6	Uncontrolled diabetic, vomiting, etiology?	Guaiac negative stools, G.I. series showed duodenal irritability, no ulcer	59.2	Duodenitis
7	Alcoholic, upper G.I hemorrhage	Died before studies in x-ray (no autopsy)	79.0	Probable Laennec's cirrhosis with bleeding esophageal varicosity
8	Systemic lupus (not on steroid therapy)	Positive L.E. test	130.0	Same as suspected

* A patient with full-blown adrenocortical hyperfunction (Cushing's disease) tested by two of us[17] had a uropepsinogen level of 961.2 mcg. per hour.

Table 3 discloses the level of uropepsinogen in patients with proved pernicious anemia as compared with several suspected of having this condition. If a patient has achlorhydria refractory to histamine stimulation, has macrocytic anemia, and has been given vitamin B_{12}, so that studies of his bone marrow are not diagnostic, this test affords the fullest measure of assurance thus far devised in a simple test to rule out a diagnosis of pernicious anemia. If a patient has a normal uropepsinogen level, it can be unequivocably stated that he does not have pernicious anemia. Studies with vitamin B_{12} labeled with radioactive cobalt are more refined, but these require technical facilities not generally available. The importance of adequate renal function and the primacy of the target organ, the gastric mucosal gland, is apparent here in these cases of hypopepsinuria.

Table 4 illustrates the effect on the rate of excretion of pepsinogen in the urine in a variety of conditions. Some are of a controversial nature, and the differential value of the uropepsinogen determination becomes apparent. Case 7 of table 4 is noteworthy in that the patient died over a weekend, and rather suddenly, from exsanguination and shock. Yet, despite the lack of additional evidence, the urine specimen obtained prior to death afforded some measure of support to the presumptive diagnosis. The value of this simple test for uropepsinogen in evaluating a patient with an endocrine disturbance and one with massive upper gastrointestinal hemorrhage is indicated by the following case reports.

Report of Cases

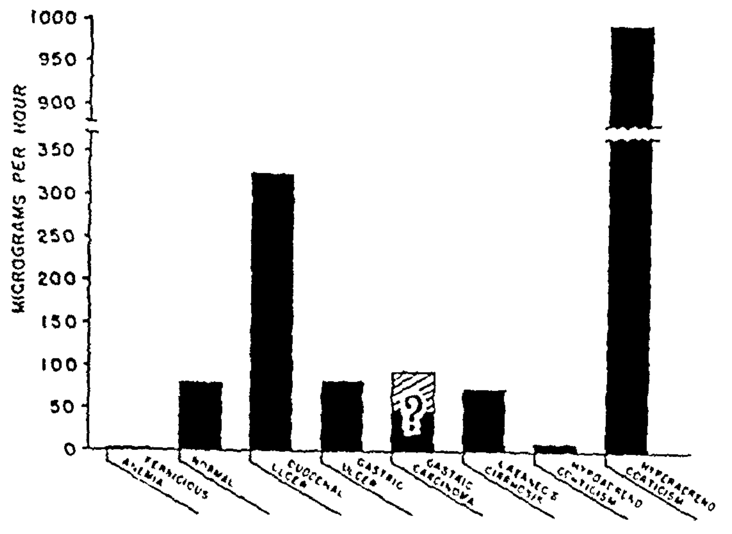
Case 1.—A 21-year-old woman noted increasing gain in weight, menstrual irregularity, and hirsutism. She was found to have borderline hypertension. Findings of a 17-ketosteroid excretion of 60 mg. per 24 hours prompted her referral to the endocrine clinic of the Pennsylvania Hospital. The endocrinologist, upon clinical evaluation, did not believe the patient had hyperadrenalcorticolism. A normal uropepsinogen value was confirmed by a normal 17-ketosteroid excretion determined in our laboratory. This patient with idiopathic hirsutism and exogenous obesity was spared expensive tests to rule out adrenocortical hyperfunction (Cushing's disease).

Case 2.—A Negro male, aged 68 years, with a 38-year history of excessive consumption of alcohol, was brought into the receiving ward in a state of shock. Hematemesis was observed, and rectal examination revealed a tarry stool. While the patient was assumed to be bleeding from esophageal varices, a balloon tamponade did not seal off the bleeding point. After 2,500 cc. of blood was given by transfusion, it became apparent it would be impossible to replace the blood fast enough; hence, an emergency gastrectomy was performed. Unfortunately, approximately six hours postoperatively the patient dislodged the endotracheal airway, vomited, aspirated a large amount of blood, and died. A preoperative uropepsinogen test revealed a level of 327.3 mcg. per hour. This is incompatible with Laennec's cirrhosis. At autopsy, gross and histological studies showed acute and chronic superficial hemorrhagic gastritis, not Laennec's cirrhosis.

It is apparent that, had routine measures to stop the flow of blood with a Sengstaken tube been continued, the patient would have died because of loss of blood. A simple urine test obtained when a barium swallow is not feasible might give the surgical member of a hemorrhage team the go-ahead signal, and the massive hemorrhage could thereby be controlled.

Comment

The figure is a graphic demonstration of the comparative levels of excretion of uropepsinogen in well and in diseased persons. The mean value for cases of duodenal ulcers is four times normal. The diagnostic value of this determination in excluding pernicious anemia is obvious when it is noted that the lowest normal value is approximately 14 times that of the highest value for cases of pernicious anemia (mean for pernicious anemia equals 1/55 of mean value for normal). The test is of no diagnostic value in a benign gastric ulcer, and its usefulness in differentiating the malignant lesion of the stomach is not determined. In the bleeding patient, its value is evident. It is probably too early to comment on the significance of the relationship of uropepsinogen to the adrenocortical-gastric axis. Suffice it to say, stress and psyche are well-known bedfellows, and both have been justly incriminated in the pathogenesis of disease. It may be reiterated, however, that, if the index of suspicion is high regarding adrenocortical hypofunction (Addison's disease) or adrenocortical hyperfunction (Cushing's disease), this test may be of special value.



Comparison of uropepsinogen levels (mean values) in well and diseased persons.

The department of rheumatology has recently undertaken a study[16] to test the reliability of this determination in "predicting" gastroduodenal complications of steroid therapy. Impetus to this investigation was recently afforded by a female patient with rheumatoid arthritis, who, without any previous gastrointestinal symptoms, suddenly suffered a perforation of a peptic ulcer.

Conclusions

If the simple technique of West, using Goodman's substrate and a curve standardized within the individual laboratory, is put to the test as the more controversial Anson and Mirsky method has been, the uropepsinogen determination may well find a place of real practical value among the tests that are simple to perform and that afford valuable clinical information.

Postmastectomy Lymphedema.—The major factors in the production of lymphedema in the post-radical mastectomy arm are failure of muscular pump and anatomic disruption of lymph drainage channels. The failure of the muscular pump action of the extremity takes place in three stages. First the arm is necessarily immobilized in the immediate post-operative period. During this stage normal muscular action of the arm, particularly the shoulder girdle musculature, is prohibited. The second stage, disuse atrophy, occurs if immobilization is continued beyond a few days. In the final stage the patient may develop a frozen or partially limited shoulder, further inhibiting the use of the extremity and contributing further to the trend of disuse and hence failure of the muscular pump. Actual interruption of lymph drainage channels through the axilla is probably the major cause of the lymphedema; however, cases can be cited in which the lymph vessels and nodes were relatively spared and yet lymphedema developed. Apparently both disuse and channel interruption factors are operative in most cases. Physical treatment, prophylactic or definitive, is aimed at minimizing the effect of the two etiologic factors. Active motion of the shoulder should be initiated as soon as feasible post-operatively, certainly by the time the sutures are removed; partial range can often be prescribed safely a few days after operation, though full range exercises may have to be delayed. The patient should be instructed during the further recovery period to exercise the arm with increasing frequency and increasing resistance, even with the use of some household articles (such as a flatiron) for weights. It has been shown that muscular activity is an efficient method of moving lymph from an extremity.—C. Long II, M.D., *Physical Factors in Post-Mastectomy Lymphedema*, *Henry Ford Hospital Medical Bulletin*, June, 1956.

KINKING OF AORTIC ARCH (PSEUDOCOARCTATION, SUBCLINICAL COARCTATION)

André J. Bruwer, M.B., Ch.B.
and
Howard B. Burchell, M.D., Rochester, Minn.

• *Roentgenographic evidence resembling a mediastinal tumor or coarctation of the aorta might, after careful study, prove to be a kinking of the aortic arch. Ten cases of this particular aortic deformity have been observed at the Mayo Clinic, four diagnosed in retrospect. Nine of the 10 patients had systolic murmurs at the base of the heart, probably the result of turbulence of blood in the region of the aortic kink. Oblique and lateral roentgenograms will usually allow the diagnosis of kinking, and confirmation can be had through angiocardiography.*

Kinking of the aortic arch is an anomaly that usually is recognized first by the appearance of the upper mediastinal shadow on the posteroanterior thoracic roentgenogram. The roentgenographic appearance frequently simulates that of a tumor adjacent to the aortic arch. Sometimes it brings to mind the deformity of the aorta that may be seen in coarctation. Furthermore, in roentgenograms taken in the lateral and left anterior oblique positions, a kink or buckle is seen in the aortic shadow, with its angular convexity at about the level of insertion of the ligamentum arteriosum.

This appearance of the aortic arch has resulted in the application of unsatisfactory and confusing names to this entity. For instance, it has been called "atypical coarctation,"[1] "subclinical coarctation,"[2] and "pseudocoarctation."[3] We prefer to adhere to noncommittal and, we believe, more accurate and less confusing designations, such as "buckling" or "kinking"[4] of the aorta. The first two of the following brief case reports present some of the features of this condition. These are taken from a group of six such cases encountered at the Mayo Clinic in which the diagnosis was made primarily.

Report of Cases

Case 1.—A 40-year-old woman first visited the Mayo Clinic in 1936 because of pain in her left sacroiliac region a few months after a fall. Her health had otherwise been good, although a cardiac murmur had been heard when she was 12 years of age. Results of examination in 1936 were essentially negative except for a basal systolic murmur of moderate intensity transmitted faintly to the vessels in the neck. The blood pressure was 150/86 mm. Hg. A roentgenogram of the thorax showed some torsion of the aorta. The patient visited the clinic on many occasions during the next 19 years, the last time being in 1955. In 1939, a stone was removed from the left ureter and hypoplasia of the right kidney was noted. Her visits often concerned episodes of thoracic pain that was thought to be consistent with angina pectoris, although the story was atypical. Her blood pressure gradually increased to 200/100 mm. Hg. Review of her electrocardiograms, including tracings recorded in 1955, revealed them to be normal aside from slight evidence of left ventricular hypertrophy. Over a period of 12 years, only minor changes occurred in the roentgenographic appearance of the cardiomediastinal configuration.

A number of roentgenologic diagnostic possibilities were entertained during observation of the patient in the above case, including aneurysm and mediastinal tumor. We now consider that the appearance of the upper mediastinum unquestionably is the result of a developmental kink or buckle of the aorta in the region of the ligamentum arteriosum (fig. 1). It is also extremely likely that this patient's murmur, discovered when she was 12 years of age, is a result of turbulence of the blood stream in the region of the aortic kink.

Case 2.—A 37-year-old woman registered at the clinic in 1954 with the main complaint of pain on swallowing. Six months previously, a thoracic roentgenogram had been taken and she had been told that she had an "enlarged blood vessel." Examination disclosed a grade 1 systolic murmur in the left infraclavicular zone transmitted to the left subclavian and carotid regions and faintly to the left upper interscapular region. Blood pressure in the arms and legs was normal. In a posteroanterior roentgenogram of the thorax, a small mass appeared to be projecting to the left at the level of the aortic arch (fig. 2*a*). This mass could not be disassociated fluoroscopically from the aortic arch. It showed evidence of pulsation, but it was impossible to tell whether the pulsation was transmitted or expansile. Therefore, angiocardiography was performed, which demonstrated that a peculiar buckle of the aortic arch was responsible for what appeared to be a mass (fig. 2*b* and *c*).

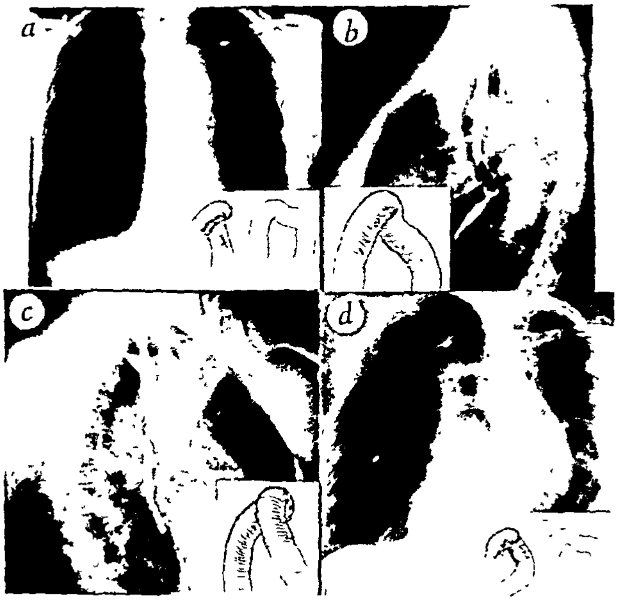

Fig. 1.—Roentgenograms of patient in case 1. Posteroanterior view, *a*, shows what appears to be a mass above aortic knob. Diagram indicates that the "mass" actually is the aortic knob, whereas what appears to be aortic knob is the segment of aorta beyond kink. Pronounced density at this point results from segment of arch beyond kink being seen "end on." Lateral, right anterior oblique, and left anterior views of aorta are shown in *b*, *c*, and *d*. The diagrams are self-explanatory. Note that aortic impression on barium-filled esophagus is made by segment of aorta beyond kink.

In another of the six cases there appeared to be some elongation and torsion of the aorta below the level of the kink, accentuating the abnormal appear-

From the Section of Roentgenology (Dr. Bruwer) and the Section of Medicine (Dr. Burchell), Mayo Clinic and Mayo Foundation. The Mayo Foundation, Rochester, Minn., is a part of the Graduate School of the University of Minnesota.

Read before the Section on Radiology at the 105th Annual Meeting of the American Medical Association, Chicago, June 13, 1956.

ance. With this in mind, we reviewed roentgenograms taken at the clinic during the last several years for which the designations "torsion of the aorta," "aneurysm of the thoracic aorta," and "left mediastinal mass" have been used. We suspected that we might find other instances of kinking of the aorta in which torsion had so distorted the appearance of the roentgenogram that it might simulate either a mass or an aneurysm. Also, we were interested to know what occurs in the region of the ligamentum when the thoracic aorta undergoes pronounced elongation.

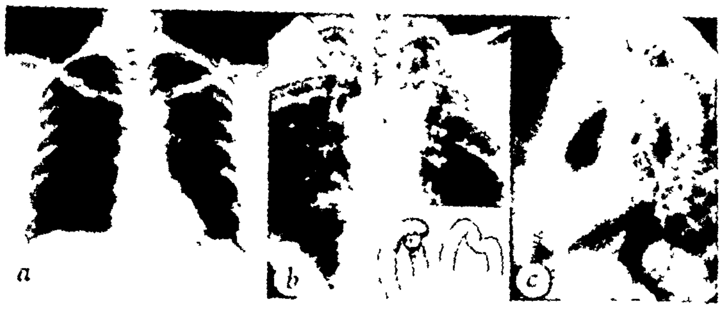

Fig. 2.—Roentgenograms of patient in case 2. Posteroanterior roentgenogram, *a*, shows double shadow at level of aortic knob. This could be interpreted reasonably as a mass adjacent to aortic knob or as aneurysmal dilatation of left subclavian artery. Angiocardiogram, *b*, in anteroposterior projection shows that the "mass" actually is aortic knob. Lateral angiocardiogram, *c*, indicating nature of aortic deformity. Arrows indicate highest level of aortic arch.

In the usual case of elongation of the aorta, the vessel takes a wide, smooth sweep over the left main bronchus and down the left paravertebral region, with enlargement of the "aortic window" (fig. 3). As the sweep of this arc increases in old age, we would surmise that either the intimate relations of the arch and left pulmonary artery are little disturbed or the tissues of the ligamentum stretch and degenerate without exerting a limiting effect on the unfolding process. If in certain cases the ligamentum did not stretch or degenerate, one might suspect that an elongated or tortuous aorta would be buckled at the site of insertion of the ligamentum. It is likely that the kink in a tortuous aorta described by Rösler and White [5] was of this nature. As the result of examination of many hundreds of roentgenograms, we found four instances of kinking of a tortuous aorta in the region of the ligamentum. One such case is presented.

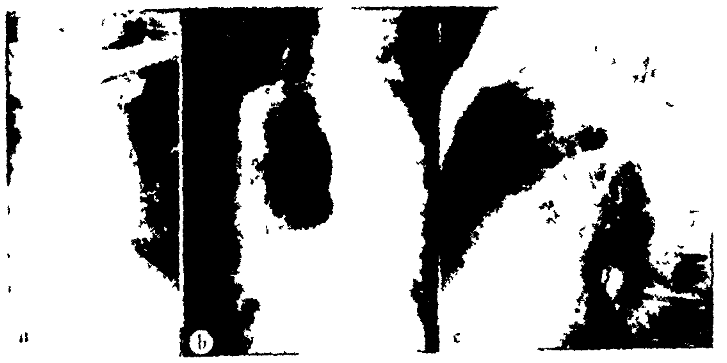

Fig. 3.—Roentgenograms showing, *a*, posteroanterior; *b*, left anterior oblique; and, *c*, lateral views of thorax demonstrating usual, smoothly rounded contour of a tortuous aorta.

Case 3.—A 52-year-old man came to the clinic because of hypertension. The blood pressure was 270/160 mm. Hg. Murmurs were not audible. Pulsations in the femoral artery were strong and not suggestive of coarctation. A roentgenogram of the thorax was suggestive of a mediastinal mass, possibly an aneurysm or a tumor (fig. 4*a*). Fluoroscopy and oblique and lateral roentgenograms showed a kink in the aorta in the vicinity of the ligamentum arteriosum (fig. 4*b* and *c*). The aorta was tortuous and elongated, with some dilatation immediately beyond the kink.

Clinical and Roentgenographic Observations

There is little in the literature on kinking of the aortic arch. Fewer than 30 cases have been reported or referred to.[6] It is likely that at least one of these cases has been reported twice. The best authenticated cases are one in which surgical exploration revealed the kink in the aorta to be at the site of insertion of a short patent ductus arteriosus [2] and one in which a retrograde aortogram revealed the kink to be at the site of a conically obliterated ductus arteriosus.[4a] The remarkable similarity of most of the published cases to each other would suggest that it is reasonable to assume that they are identical in cause to the two cases just mentioned. Roentgenologically, aortic kinking is of interest in that it so commonly simulates a mediastinal tumor. In the reported cases, as well as in some of our own, the practical significance of angiocardiography or retrograde aortography has been demonstrated, thereby obviating surgical exploration.

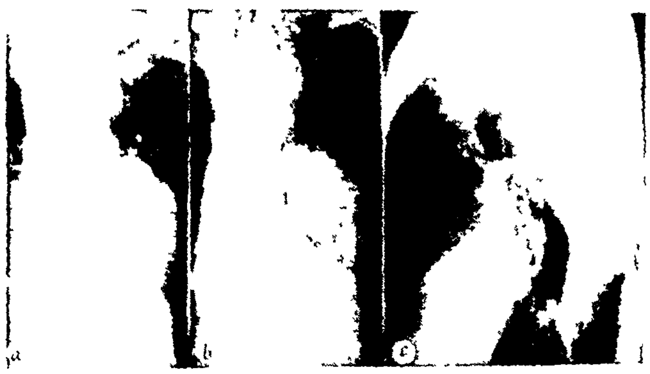

Fig. 4.—Roentgenograms of patient (case 3) with severe hypertension In posteroanterior roentgenogram, *a*, there appears to be a large mass at the left hilus. Heavier penetration, *b*, shows the "mass" extending down behind the heart. Lateral view, *c*, shows aorta kinked at level of left main bronchus (ligamentum); the "mass" is due to pronounced torsion and moderate dilatation.

The deformity of the aorta frequently seen in coarctation [7] is closely simulated in some of these cases, especially on posteroanterior roentgenograms This has given rise to the afore-mentioned designations of "pseudocoarctation" and "subclinical coarctation," terms that are not satisfactory. In their favor can be cited examples of patients with unquestionable coarctation who have lived to middle or old age without much disability and with relatively good pulses in the legs. However, to use the term "subclinical coarctation" for cases of kinked aorta in which other clinical or roentgenologic features of coarctation are absent is to make the untenable implication that the kinked aorta is a type of coarctation without coarctation. The fact that the kinking of the aorta occurs where the ligamentum arteriosum attaches to the aorta does not allow one to assume that such kinking is pathogenetically related to true coarctation. It is more likely that the aorta is kinked at that particular site because it is the logical location where traction would occur on the aorta. The predisposing cause for the kink is the traction of the ductus or ligamentum; the exciting cause is unknown but probably is related to an unusually short ligamentum or ductus or an unusually long aortic arch. Thus, we believe that "kinking" or "buckling" of the aorta is a preferable term and that the condition probably has nothing to do with true coarctation. Instances of "pseudocoarctation" could just as well be called "pseudotumor" because the posteroanterior roentgenograms in so many of them suggest the presence of a tumor. Furthermore, such lesions are never associated with notching of the ribs.

The usual presence of systolic murmurs in these patients if of interest. Nine of the 10 patients had systolic murmurs at the base of the heart, probably the result of turbulence of blood in the region of the aortic kink. In 2 of our 10 patients, murmurs had been detected in childhood and the patients had been told they had "leakage of the heart." In one of the patients referred to by Di Guglielmo and Guttadauro,[4a] the murmur had resulted in an inaccurate diagnosis of congenital heart disease.

Differential Diagnosis

The appearance of a mediastinal mass on the roentgenograms in their first case of kinked aorta led Souders and associates [2] to make a diagnosis of Hodgkin's disease. In three of the cases subsequently described in the literature, the suspicion of a mass was aroused by the appearance of the posteroanterior roentgenogram. Angiocardiography was performed in all these patients and revealed the true nature of the condition. As so commonly occurs, evaluation of a mediastinal mass is usually no clearer after fluoroscopy than it was before. In a recent study, Tucker and Bruwer [8] found that the interpretation of the roentgenograms was more often correct in the evaluation of a smooth-contoured left hilar mass than was the fluoroscopic interpretation. Furthermore, angiocardiography was vastly superior as a method of differentiating a mediastinal mass from a vascular shadow. In kinked aorta, a good oblique (usually a left anterior oblique) roentgenogram or a lateral roentgenogram usually will reveal the true state of affairs. If any further doubt remains, angiocardiography should be done.

Roentgenograms in cases of kinked aorta frequently give an appearance in which the aortic deformity simulates that seen in many cases of true coarctation. This similarity becomes more pronounced in those cases of true coarctation of the aorta in which roentgenologic evidence of notching of ribs is absent. Fluoroscopy may carry the similarity further, in that some aortic dilatation may be present beyond the anomaly in both conditions, and this can be well demonstrated by the impression of the dilated segment on the barium-filled esophagus. The differentiation from coarctation of the aorta depends on such findings as palpable collateral vessels, diminished pulses in the abdominal aorta and legs, hypertension in the upper extremities and disproportionately low blood pressure in the legs, and evidence of left ventricular enlargement.

Aneurysms may have to be differentiated, which requires investigations such as serologic tests for syphilis, inquiries into previous thoracic injuries, evaluation of oblique roentgenograms, and angiocardiography. Congenital aneurysms in the segment of the aorta between the origin of the left subclavian artery and the ductus arteriosus or ligamentum arteriosum usually show characteristic roentgenographic features.[9]

The murmurs that usually occur in patients with kinking of the aorta may lead to an unwarranted diagnosis of either congenital or acquired heart disease. Heart disease has been present in several cases,[10] but in most instances the murmurs are attributed best to turbulence of the blood stream in the kinked segment of the aorta.

Summary

Ten cases of kinked aortic arch have been encountered at the Mayo Clinic. The points of particular interest in this condition are that (1) it may resemble a mediastinal tumor on the posteroanterior roentgenogram; (2) it may bear roentgenographic resemblance to the aortic deformity that may occur in coarctation; and (3) the patients frequently have systolic murmurs that may give rise to an erroneous diagnosis of organic heart disease.

Intestinal Obstruction in Infants.—The most common cause of intestinal obstruction in the newborn is atresia. In a collective review of the subject in 1951, Evans estimated that each year 3,000 babies in the United States and 50,000 babies in the world are affected with this condition. The most commonly accepted etiologic theory is that during the fifth to twelfth week of intrauterine life the intestinal tract goes through a solid stage for a short period, that vacuoles then appear which coalesce and reestablish the lumen, and that an arrest in this vacuolization causes the atresia. Until recently, obstruction in the newborn was almost always fatal. Up until 1950 there were only 125 successfully treated cases recorded in the literature. Recovery is not a rarity today, but the mortality from intestinal obstruction remains high. Prematurity and associated anomalies are certainly the greatest cause of the high mortality, and not much can be done about those factors; but delay in diagnosis and treatment, which is a considerable factor, is subject to correction. Physicians who attend infants must constantly keep obstruction in mind.—O. Tuschka, M.D., and D. Hyde, M.D., Intestinal Obstruction in the Newborn, *California Medicine*, April, 1956.

ADVENTURE IN PEDAGOGY

George E. Miller, M.D., Buffalo

• *Twelve medical faculty members, with the conviction that medical education can be improved, undertook an investigative analysis of fundamental educational principles. In 20 hours of relatively unstructured discussion, using a chairman trained in sociology and anthropology and the dynamics of learning, there resulted a broadened understanding of and change in attitude toward the teaching processes being practiced. A few of the conclusions arrived at revealed that teachers may be major obstacles to student learning; that people learn what they want to learn; and that learning is largely an emotional experience. The student must be helped in wanting to learn rather than just to know.*

The results of this preliminary study, while giving certain participants a new self-awareness along with a new sensitivity to student needs, have made teaching far more difficult than before but have provided a personal satisfaction not previously known.

The long history of medical education on this continent has been marked by many turnings, which might lead an uninitiated observer to describe the path from student and preceptor of 1750 to the student and preceptor of 1950 as the completion of a full circle. The more generous would look upon it as a spiral in which each step was supported by those that went before. Among those steps three would stand out boldly: the steady increase in required years of formal education; the geometric progression of data to which the student is exposed, data that have been compounded in complexity as the contributions of chemists, mathematicians, and physicists have been incorporated into medical lore; and the fractionation of man into his component parts, each of which has been claimed by a belligerent corps demanding a larger share of the student's time. All of these things, Jay Tepperman has said, give our students a strange resemblance to "Belgian geese being fattened for *pâté de foie gras.*" It is perhaps a resulting sense of discontent that today has led us to reverse the field busily, to resynthesize the whole man with the help of sociologists, anthropologists, and clinical psychologists who have invaded our halls (to our enormous benefit, I need not add), and to slash away at course content, hoping our excisions will not remove some vital rung of the ladder a student must climb. Even the traditional structure of curriculum has been shaken by the demonstration that Western Reserve students, too, can pass national boards.

Need for Improvement in Quality

At the heart of this varied violence lies a conviction that improvement in the quality of medical education can be achieved. Yet there seems a curious omission in our methods. As physicians we regularly employ consultants who illuminate a problem by the special body of information or the particular competence they enjoy. But in our struggles as educators we ignore with equal regularity the potential contribution of those who have devoted their professional lives to the study and development of educational principle and practice. In all of higher education, including medicine, a degree and a clean collar are looked upon as adequate preparation for the heavy responsibility of teaching. Faced with this responsibility, most of us play it by ear and very shortly develop firm and unshakable belief in the propriety of what we are doing. This state of affairs is encouraged by the fairly general, if tacit, agreement that, if a man is appointed to a teaching position on the basis of scientific productiveness or professional competence, his proficiency as an educator will take care of itself. Perhaps the time has come to face up to the fact that many of us do not know what we are doing as teachers, that those of us who do learned it accidentally and cannot readily communicate it to others.

Investigation of Teaching-Learning Process

Such a confession is about as easy to make as an admission that one has no sense of humor. But, after two and one-half years of preliminary discussion, 12 University of Buffalo School of Medicine faculty members reached a point of willingness to accept this as a preliminary hypothesis. And with relatively open minds we set out to learn whether anything might be done to modify our ignorance of fundamental educational principles, if such actually existed.

In the selection of a guide to lead us through this wilderness, we were unusually fortunate. Nathaniel Cantor is administratively designated as the chairman of the department of sociology and anthropology in the college of arts and science and the school of education, but his interest and study has been the dynamics of learning. His vivid personality and disregard of professional jargon immediately dissipated the kind of communication barrier that at least three other medical schools encountered when they sought similar guidance from professional educators. Our group spent 20 hours together in relatively unstructured discussion, using as a resource only Cantor's book "The Teaching-Learning Process."[1] The broadened understanding and change in attitude that grew out of the experience was most dramatically demonstrated in tape recordings of the sessions. Although part of the impact is lost in transcription, I would like to describe several things that came sharply into focus.

We recognized very early that people learn what they want to learn. Of the many illustrations that immediately spring to mind, I might cite the student who

has difficulty recalling the sequence of the Krebs cycle but may have at his finger tips the batting average of every player in the major leagues and the telephone numbers of 12 attractive girls. Shall we call him stupid, perverse? Or shall we dismiss the whole matter by remarking that he must be poorly motivated, since anyone who wants to be a physician should also want this piece of information. Such a comment relieves the teacher of any further responsibility, but it helps the student very little. It also implies that the teacher can decide what the student should want to know, which is patently absurd. But it does not deny the instructor an opportunity to help the student to want it. Let the teacher who will, establish a relationship between learning the Krebs cycle and becoming a physician, and he will be unable to stop the student from learning it eagerly and enthusiastically. For motivation relates not only to the distant goal but to each of the stepping stones that lead there. The teacher who asks the student to accept the relationship on faith asks more than he himself would be willing to give.

A closely related principle reminds us that knowledge and learning are different. In any medical faculty there is always a large body of opinion that emphasizes the importance of facts and encourages the accumulation of factual data through the simple device of making them the subject matter of examinations. This is done with complete sincerity in the belief that education is an intellectual exercise. But with a little insight the least of us could amass in a single hour an overwhelming body of evidence that true learning is largely an emotional experience. Most of what we learn at medical meetings vanishes overnight. The things we retain are those items that somehow kindle a spark, arouse curiosity, or incite anger or disagreement or laughter. And for each of us these things are different, for learning is also very personal. To concentrate upon facts, arbitrarily selected, as cold and bloodless things is to deny their vitality. Facts are too important to pass as idle conversation. We should not possess them. They should possess us.

We also reached agreement that true learning implies change. And here dilemma is encountered, for the first law of thermodynamics, the law of inertia, applies with equal force to the area of learning. In the course of 10 weeks, participants in these seminars became painfully aware of this principle. As some understanding of the dynamics of learning was gained, it was clear to all that we spent a good deal of time defending our own position on education, resisting change by any method we could devise, including the classic techniques we had seen our students use: tardiness, failure to read material previously agreed upon, shifting the focus of discussion when it came close to tender spots, obscuring the issue by vagueness, and indulging in hairsplitting, self-deception, and hostility.

But, under the skillful guidance of a leader who made no moral judgments of these tactics, who accepted them as an inevitable part of the learning process, who did not deny them by authoritarian dictums, progress and change took place, in a direction and at a pace that was acceptable to the group. The unskilled leader, failing to recognize these things, might have demanded that the group move in his direction, at his pace, and would have succeeded in blocking true learning by providing an object upon which resistance to change could be attached. It is frightening to recall how common this practice is in orthodox teaching, where change is expected, but only in the direction that the teacher, the authority, decrees.

If the first three principles are sound, the fourth, that true learning requires freedom, follows naturally. Whenever freedom in education is discussed, however, there is immediately an outcry from those who equate freedom with anarchy. Lest we fail to understand how men who have lived in a democracy can complete such an equation, we might recall that our educational system has usually been authoritarian (even in the heyday of free electives) and that teachers, too, resist change. Freedom is used here in the Websterian sense as the state of not being subject to an arbitrary external power. But who would deny that medical faculties in general, and physicians in particular, are often arbitrary in their exercise of power? A curriculum that is content-and-examination-centered provides freedom for the student to grow in only one way. And those schools that have liberalized their curriculums provide only as much freedom for individual student development as faculty members will allow. The usual tendency of a faculty is to encourage growth in its own image. The student who does what he is told, gives back the "official pitch" when he is called upon, and performs his work without question is usually looked upon as a good student, while the one who analyzes and challenges faculty statements and accepts nothing without supporting evidence is tagged an annoying little beast who probably needs a psychiatrist. The encouragement of this kind of student independence may make life considerably more trying for the teacher. Traditional teaching is relatively easy, but helping a student to learn is an exhausting occupation.

Role of Teacher

Examined in these terms, a more precise definition of the present role of the teacher in the learning process forces the conclusion that teachers may be major obstacles to student learning. It took participants in this seminar 12 hours to admit this openly. It would be unrealistic for me to expect a reader to accept it in 12 minutes. But the painful self-examination led us inevitably to such a terminus. Why? Because teachers of medicine are very much like everyone else. They have developed not only an understanding of a large body of data and a variety of technical skills but also an image of themselves. And whatever threatens this image is suppressed. The teacher preaches, and the student responds. The right answer is the answer the teacher wants, and both teacher and student often fail to recognize that true learning begins with not knowing the answer.

Students detect this long before they get to medical school, but most medical school teaching does nothing to suggest the desirability of change. How can they believe we encourage independence, when in biochemistry they are taught to reply that diabetes is the result of an overproduction of glucose while in physiology it is due to underutilization, and when in pediatrics only digitoxin can be used to treat congestive heart failure and in medicine only whole leaf digitalis? If they ask why these things are so, they are told in essence, "Because I say so." Not this crudely, I grant. But if one listens to tones, to shadings, to the meanings that words conceal rather than the words themselves, it becomes evident how rarely a teacher allows the image of himself to be threatened. Instead we use students to support this image. We expect them to defer to us, to respect and admire us, to mimic us, and to do well when examined by others on the material we are presumed to have taught them. And instead of giving them the help and encouragement they need, we exploit them for our own needs again and again.

The professional responsibility of the teacher should be obvious. It is based upon a fundamental respect for the individual student, an awareness of the dynamics of learning that must allow each student the freedom to be different and that encourages challenge. It is concerned with helping the student to want to learn rather than to know. It involves an honest effort to understand the student rather than to judge him. This should be easier for the physician-teacher to understand than for almost any other. The physician's occupation is to provide a professional service to patients. He attempts to understand their problems and to be of use in their solution. He makes no moral judgment of the illness and suffers no offense or loss of prestige if the patient ignores his advice or fails to respond to his best therapeutic efforts. He is secure in his role. It is this kind of professional service that the teacher owes the student and, if he gives less, he is a fraud.

While this indictment is broad, it does not include all medical teachers. And, of those it does embrace, a significant number might say that they would like to teach in this understanding, challenging, encouraging way but are forced by departmental policy, curriculum arrangement, state and national board examinations, or some other restriction to conduct themselves in an orthodox, authoritarian fashion that they recognize as second rate. This brings me to the final point, the nature of compromise. There are realities that we all must face. There are limits beyond which we cannot go, limits of time and space, external and internal forces that must be respected. To recognize such limitations, however, is quite different from using them as an excuse for not doing something you really do not want to do anyway. As Cantor puts it, "Even in a strait jacket there is room for some movement." We do what we can when we can do it. But first we must understand ourselves.

Results of Investigation

One might properly ask what happened to the faculty members who went through this experience. I can answer that none of them has been dismissed for heretical teaching. We have no quantitative measure of their change nor any evaluation of its quality. But 9 of the 12 have a new awareness of themselves, a new sensitivity to their students' problems. They find teaching a much more difficult task than it was before, but it provides them with a satisfaction they had not previously known. And they recognize their limitations, their need for further growth and development as teachers.

Because of this outcome we have been encouraged to travel further down this avenue, which seems to lead toward an important juncture of the problem in medical education. With generous support from the Commonwealth Fund, a more elaborate program has been developed, which will allow members of our own faculty, with selected visiting faculty from other medical schools, to explore in greater depth such fundamental principles of education as these and to put them to the test of practice in a medical context. Under medical school direction, an annual series of seminars and workshops, beginning in September, 1956, will continue to use the wealth of skill and information in the school of education and college of arts and sciences that might contribute to a solution of the problems we face as medical educators.

In addition to the teaching-learning process, it has seemed worthwhile to investigate, in such seminars, the nature of the medical student, who he is, and where he comes from, what his background is in psychological and socioeconomic terms, how the selection process influences his development before he arrives in medical school and the kind of response he makes to a medical curriculum, what the effect of the medical school environment is upon his ability to learn and to grow, and what kind of person he becomes professionally and socially. Some attention will also be given to the evolution of higher education in general and medical education in particular, for it is difficult to comprehend where we are or where we are going without some knowledge of where we have been. The broad field of evaluation of the outcomes of learning in a medical setting will also be considered: Are our present methods truly evaluation or simply measurement of acquired information? What are the principles that underlie the selection of a specific technique? How may the variety of evaluation techniques be most effectively incorporated into the educational pattern of medicine? Finally, some attention will be devoted to the broad subject of communication, the methods and materials of instruction. But only finally, for methodology is simply handmaiden to principle; without principles methods become empty and isolated efforts.

Is it all worthwhile? My biased opinion is often balanced by those who call this talk of educational principles nonsense, who remind me that the work of the teacher is to cram into the student as many facts as possible in the time allotted. (They further point out that the time allotted their subject is not enough.) And they may be right. But while they man their bastions against attack, we, the enemy, will be having a rousing adventure in pedagogy.

ANTIGENIC POTENCY OF POLIOMYELITIS VACCINE

INFLUENCE ON DEGREE AND DURATION OF VACCINE EFFECT

Jonas E. Salk, M.D., Pittsburgh

• *Groups of children who had been given different doses of a poliomyelitis reference vaccine A in the spring of 1955 were all reinoculated in the spring of 1956 with the same dosage of vaccine J. Quantitative studies demonstrated both the persistence of the antibody over the course of a year and the increase in titer in response to the third dose given at this time. To secure an optimum response to the booster injections it was necessary to give an adequate dose in the primary antigenic stimulation. After the booster injections the antibody titers equaled or exceeded those found in a group of convalescents from recent type 1 paralytic poliomyelitis. The nonliving, nonmultiplying virus antigen reproduced the serologic effects of naturally acquired infection-immunity. Seven lots of commercially prepared vaccines administered to 186 subjects, compared with five lots of laboratory-prepared vaccine in 115 subjects, proved to be equally satisfactory as to potency and uniformity in raising the antibody titer. In 4,617 subjects who received three inoculations, only 224 had antibody at a level of 1:64 for all three types before inoculation, but 4,548 had antibody at this level for all three types after the third inoculation. Six lots of commercially prepared vaccine were used in a study of 214 subjects as to the advantages of a second inoculation, and the rise in titer produced by the second inoculation was clearly demonstrated for each lot, so that a low proportion of response to the first dose was converted to a high proportion of response by the second dose.*

As a result of recent studies on vaccination against poliomyelitis, much information on the immunology of this disease has accumulated. The purpose of this paper is to present a number of facts on the basis of which immunologic thinking has been clarified and a practicable method of immunization devised. Before presenting the immunologic problems, it might be well to review very briefly the effect of the experience of the past year upon the question of safety, this being the foremost of the two considerations of practicality, i. e., safety and effectiveness.

Vaccine Safety

It is self-evident that, for vaccination against poliomyelitis to be practicable, it must not be attended by any risk that would tend to discourage its use. In preliminary studies and in the field trial it was established that antibody production and immunity can be induced without risk of inducing paralysis; this has been reaffirmed in an accumulating experience in the United States and in other countries. It is now clear that this vaccination procedure does not necessarily possess an inherent risk, and this is true regardless of the nature of the strains of virus employed.[1]

The destruction of infectivity of poliomyelitis virus by formaldehyde is an orderly chemical process and, when properly carried out, with due attention to details and to the principles involved, results in a reliably predictable effect.[1] Although safety tests are performed on a relatively small fraction of each batch, they provide a substantial degree of confidence. In addition, the index of safety for each batch in a given series can be extended, far beyond the degree of assurance that the test of a single batch provides, by using the safety test as an indicator of consistency, or as a measure of reliability, of the manufacturing process. The concept of the "built-in safety factors" of the process, together with the required tests applied during processing and at the end, and, of equal importance, the reasonable interpretation of test results, have resulted in an order of safety that extends by a considerable margin the degree of confidence provided by the results of tests of each individual vaccine lot.

The several inferences[2] that the theoretical considerations were unsound, or were not applicable under conditions of large scale manufacture, seem not to have been supported by time. These inferences were drawn from the misinterpretation of failures of inactivation as having theoretical significance. When the occurrence of inactivation failures was interpreted as indicating need for attention to technical details and when corrections were introduced, consistency was achieved; the importance of consistency as an applicable requirement for safety then became generally accepted.[3]

Immunologic Objectives

Even though it will not be necessary for elimination of epidemics of poliomyelitis to await full vaccination of all susceptible persons, the nature of the infectious process, and of the immune mechanism, is such that it would be desirable for vaccination to be effective in each individual inoculated. It would be desirable, too, that there be a high degree of confidence that the protective effect, once induced, persists for long periods of time—preferably for the lifetime of the individual. Although it is too soon to be concerned, in a practical sense, about duration of immunity in terms of lifelong effects, since the full potential of the initial effects is still to be demonstrated, there is, nevertheless, sufficient basis for considering, from the theoretical viewpoint, whether immunity is likely to be of long or short duration. Data now available, when considered in the light of the immunologic principles and mechanisms involved, permit interpreta-

Read before the General Scientific Meetings at the 105th Annual Meeting of the American Medical Association, Chicago, June 11, 1956.

tions and predictions concerning durability of immunity and probable degree of effectiveness. Time will reveal the reasonableness of any predictions that may be inferred and the extent to which the data now available have been critically examined and soundly interpreted.

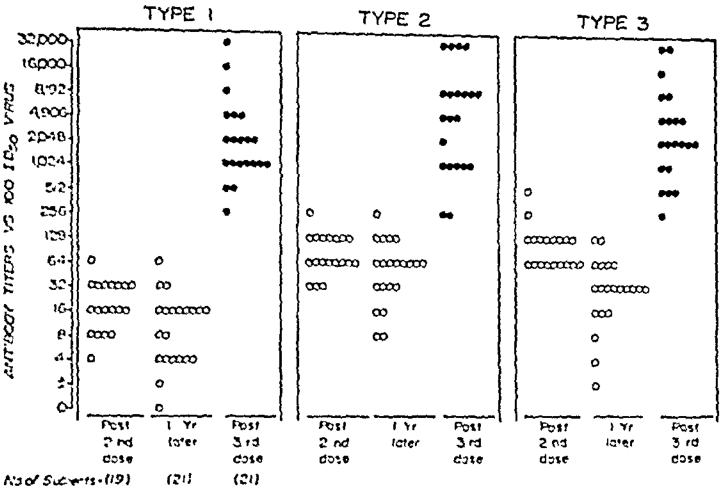

Fig. 1.—Persistence of primary response and degree of booster response. Two 1-ml. doses of reference vaccine A given two weeks apart and 1-ml. dose of vaccine J given one year later in children without antibody for any type before vaccination (± = trace of antibody at 1:4 dilution; 0 = antibody level lower than 1:4).

Mechanism of Immunity

Many studies have shown that immunity to paralysis exists when antibody is present in the serum.[4] More recently it has been revealed[5] that, if a state of immunologic hyperreactivity exists, immunity to paralysis can also exist, even in the absence of a demonstrable level of circulating antibody. This observation has now been confirmed by others[6] and reaffirmed in the further extensions of our studies.[7] Hyperreactivity must be of such degree that, after contact with virus, antibody formation will begin sufficiently rapidly to intercept virus before it can reach the central nervous system. Since the incubation period after natural exposure, and before invasion of the central nervous system, is 10 to 12 days,[8] and sometimes longer, it is understandable how a mechanism such as this does operate in the prevention of paralysis in poliomyelitis. As pointed out many years ago by Paul,[8] and referred to again by Bodian[9] and by Horstmann,[10] paralysis in poliomyelitis is a secondary consequence of a primary systemic infection. Thus, if immunologic hyperreactivity is induced by vaccination, then subsequent contact with the virus under natural circumstances should occur without risk of paralysis, since accelerated antibody formation should prevent invasion of the central nervous system, even though the pharyngeal or intestinal infection had not been prevented.

There is evidence from animal experiments that indicates that just demonstrable levels of serum antibody appear to be adequate for preventing invasion of the central nervous system. However, evidence from field tests of the prophylactic effect of gamma globulin[11] and of a single dose of vaccine[12] suggests that levels of antibody just below the range of detectability are also protective against paralysis. Further evidence, referred to above,[5] illustrates that, in cases where antibody is not detectable, paralysis may be prevented if re-formation of antibody is sufficiently accelerated to provide effective concentrations prior to the time when invasion of the central nervous system might occur. Depending upon the degree of immunity engendered, infection may be limited in such a way that paralysis does not ensue; however, if the intensity of the immunity induced is sufficient, virus multiplication at the portal of entry may be limited even to the extent that the establishment of infection is prevented.[13] Evidence in support of this has been reported by Howe[14] in studies with chimpanzees.

Immunologic Effects of Vaccination

Although there is wide variation in antibody response among individuals, it is evident from available data that vaccine potency does not influence the degree of variation in response among individuals, even though it does affect the level at which the variations occur. When vaccine dosage is varied within certain limits, the mean response induced varies with the size of the dose. Because of the wide range of variation of individual responses, discrimination between vaccines, with respect to relative potency, cannot be made by studies in single subjects; studies in groups of reasonable size will reveal the quantitative aspect of the dosage-response relationships.

In studies reported previously, it was shown that vaccine potency affects the degree of primary antibody response. However, it was not known to what extent the potency of vaccine used for primary stimulation affects the degree of secondary, or booster, response. Accordingly, groups of children who had been given different doses of reference vaccine A, in the spring of 1955, were all reinoculated in the spring of 1956, with the same dosage of vaccine J. The kind of results obtained are shown in figure 1, which illustrates the levels of antibody observed two weeks after the second dose of 1 ml. of reference vaccine A, the persistence over the course of a year, and the response to the third dose given at this time. The findings, following each of the different dosages of reference vaccine, are summarized in figure 2, which indicates the geometric

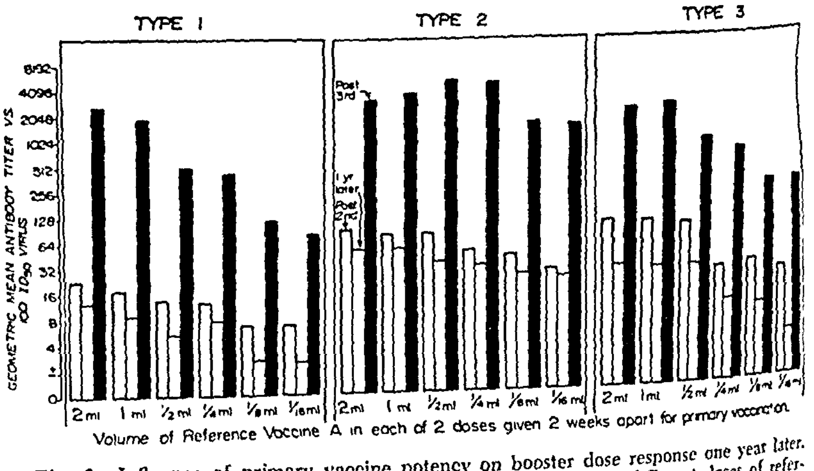

Fig. 2.—Influence of primary vaccine potency on booster dose response one year later. Groups of 20-30 subjects with no prevaccination antibody given different doses of reference vaccine A and 1 ml. of vaccine J given one year later.

mean levels observed at each of these intervals. It is apparent from the data for types 1 and 3 that the degree of response to the booster injection was affected by the dose of vaccine used for primary antigenic stimulation. This relationship is less evident for the type 2 component. Although the reason for this difference is not fully understood, it may, in part, be explained if the concentration of type 2 antigen in this vaccine is in sufficient excess so as to have shifted the range of the response to the plateau portion and away from the steep portion of the sigmoid curve that usually describes dosage-response effects of this kind. Attention has been called previously to the difference in antigenic behavior of the type 2 antigen insofar as it seems to exert a more potent effect than the types 1 and 3 antigens.

Antibody response after the third dose in each person is shown in figures 3 and 4. It is of interest that all in these groups developed a measurable level of antibody after three doses of vaccine, even though there was as much as a thirty-two-fold difference in potency of the material used for primary vaccination. The data in figure 3 show, also for comparison, the levels of antibody observed in a group of recent convalescents from type 1 paralytic poliomyelitis. The vaccine of higher potency induced levels of antibody equal to, or greater than, those observed after a naturally acquired paralyzing infection, whereas vaccine of lesser potency induced effects that were measurably less than those induced by infection. Thus, it is evident that it is possible to equal or to exceed the immunologic effects that follow infection, if attention is given to the quantitative factors that influence immunologic reactivity to a noninfectious vaccine. It would follow from this, therefore, that it is not necessary to use infective virus to simulate the effects of naturally acquired infection-immunity, since the immunologic effects can be reproduced by a nonliving, nonmultiplying virus antigen. This is not a new concept in immunology, but one that has not been as widely accepted as the evidence appears to warrant.

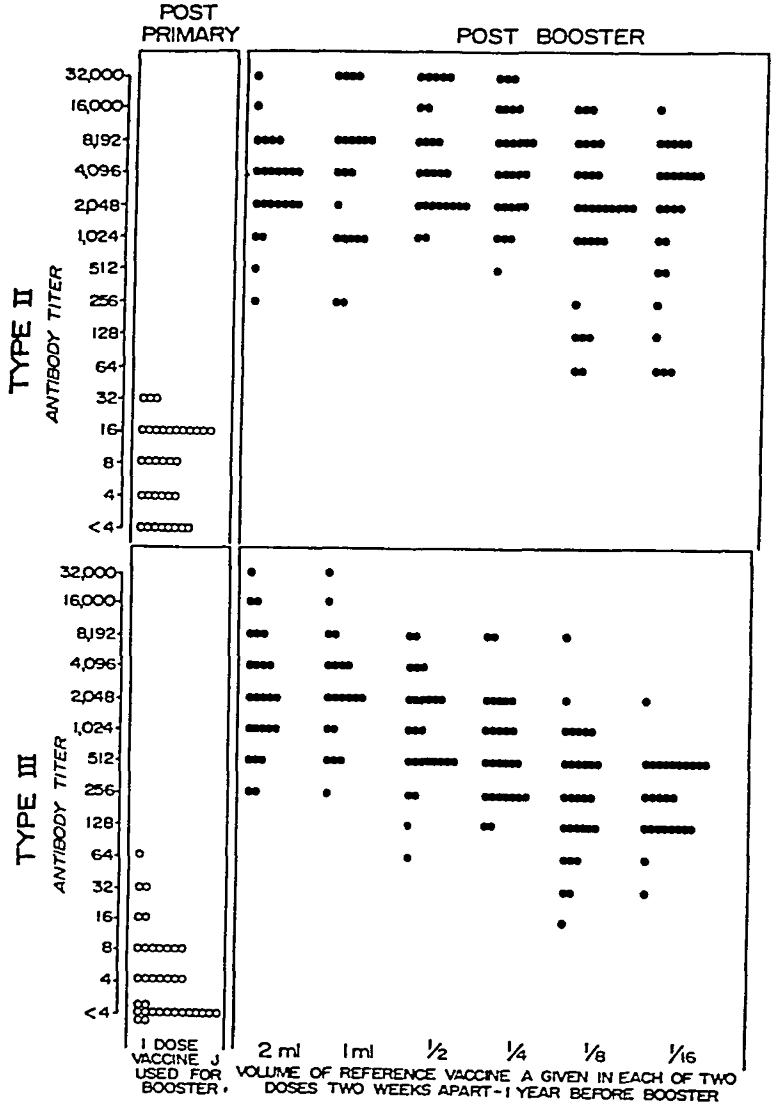

Fig. 4.—Antibody response (types 2 and 3) after booster dose in relation to potency of vaccine used for primary inoculation.

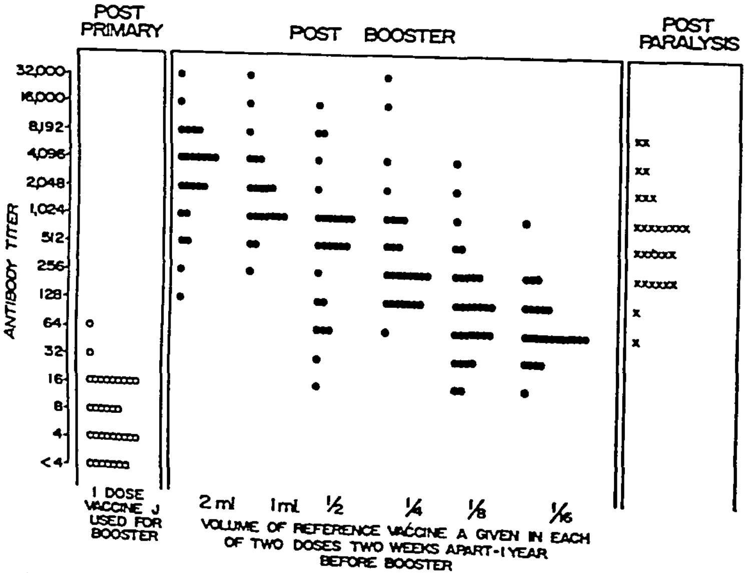

Fig. 3.—Type 1 antibody response after booster dose in relation to potency of vaccine used for primary inoculation and as compared with antibody titer following natural infection.

To illustrate the extent to which commercially produced vaccine can and has induced effects similar to those described for laboratory produced material, a comparison is shown in figure 5 to illustrate the levels of type 1 antibody that developed after the third dose in children with no prevaccination antibody for any type who had, one year earlier, received two doses, two weeks apart, of vaccine produced for general use. There were seven lots of commercial vaccine and five lots of vaccine produced in this laboratory. The vaccine used for the third dose was one of average potency from among the group for which the data on laboratory produced vaccine are shown; the response to a single dose of the vaccine J used for "booster" is also shown in figure 5, and was shown in figures 3 and 4. It will be necessary to study in more detail those individuals in whom there seemed to be less response than for the average, and to determine, if possible, the factors that might be responsible; there has not yet been time to repeat these tests.

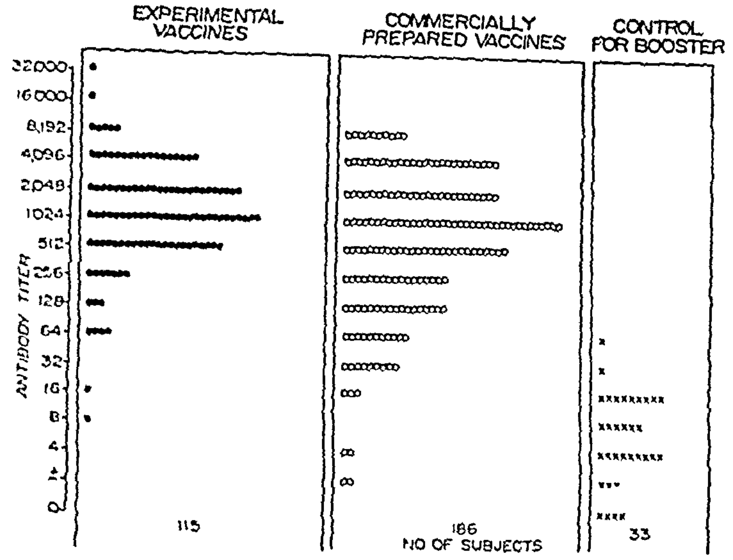

Fig. 5.—Comparison of experimental and commercially prepared vaccine. Type 1 antibody titers after booster dose with vaccine J in groups with no prevaccination antibody given two primary doses with vaccines indicated.

The point of particular significance is the fact, evident from an examination of data on the seven individual vaccine lots (fig. 6), that the variation in type 1 potency of five of the seven lots did not differ significantly from that of the experimentally produced vaccine. Thus, it would appear that the potency test, as employed for discriminating between lots of vaccine, could be expected to produce the degree of consistency here observed, when the criteria used to guide selections are those suggested by these data.

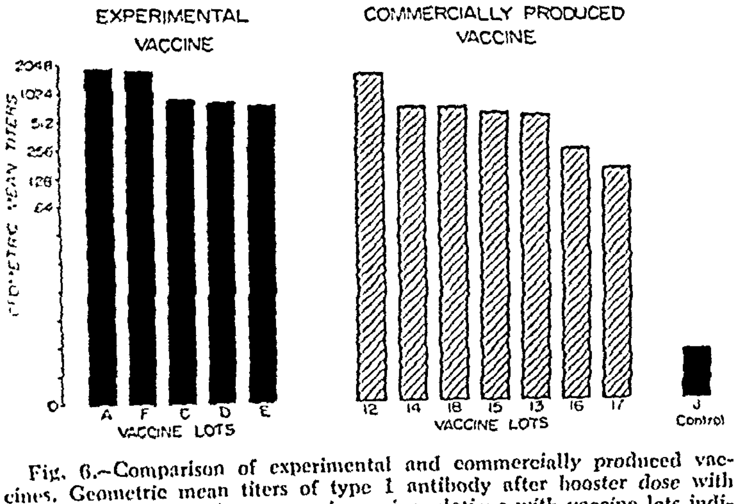

Fig. 6.—Comparison of experimental and commercially produced vaccines. Geometric mean titers of type 1 antibody after booster dose with vaccine J in groups given two primary inoculations with vaccine lots indicated.

As was to be expected, and as is clear from the foregoing data, individual variation in responsiveness to vaccination exists, just as does variation in immunologic response to infection; however, it is also clear that the significance of such variation, in terms of the prevention of disease, can be reduced by the administration of sufficiently potent vaccine and by adequately spaced multiple inoculations. Thus, there are some individuals who do not respond to the first dose of vaccine but who would have responded if potency had been greater. On the other hand, the use of multiple inoculations provides a more efficient way of insuring uniform response—a fact well known in immunology and demonstrated again in man and in experimental animals.

The objective to be achieved, either by increasing antigenic potency or by the use of multiple inoculations, is the conversion of all who have no antibody to any of the three types to a state in which they possess antibody to all three types. The degree of success that it has been possible to achieve in groups larger than those described in the data presented thus far can be illustrated by results of studies in groups consisting of more than 5,000 school children. A simplified procedure for determining antibody response was used, but one that puts vaccination to a particularly severe test. The procedure employed involved the determination of the presence or absence of antibody in a drop of blood from a finger-prick, tested in such a way that the positive or negative result indicated the presence or absence of antibody in a serum dilution of 1:64 as measured against approximately 100 T.C.I.D.$_{50}$ (tissue culture infectious doses) of virus of each type. Although a positive test for antibody indicated that it was present at a serum dilution of 1:64 or greater, a negative test did not necessarily mean that antibody for the particular type was not present.

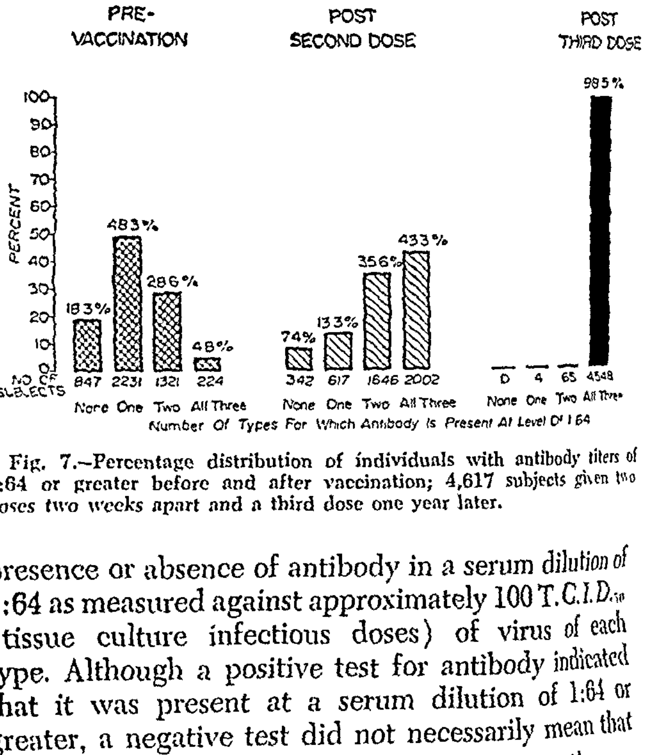

Fig. 7.—Percentage distribution of individuals with antibody titers of 1:64 or greater before and after vaccination; 4,617 subjects given two doses two weeks apart and a third dose one year later.

From figure 7 it is seen that, before vaccination, of the 4,617 subjects who had received three inoculations and for whom blood test information was available, only 224 had antibody at a level of 1:64 for all three types; 1,321 had antibody for two types, 2,231 had antibody for one type only; and 847 had no antibody for any type detectable at a level of 1:64. After two doses of vaccine, given two weeks apart, there was a shift in pattern, which is shown in the center set of columns and which indicates a reduction in proportion of those with no antibody, or antibody for but one type, and an increase in the proportion of those with antibody for two or three types, at a level of 1:64 or greater. After the third dose, given one year later, the shift was such that 4,548 out of the total of 4,617, or 98.5%, had antibody for all three types, at this level.

The effects described were induced with the use of two doses, 1 ml. intramuscularly for each dose given two weeks apart, of commercially prepared vaccine, followed one year later by 1 ml. intramuscularly of laboratory prepared vaccine of average potency as compared with commercially prepared material. The vaccines used are the same as those referred to in figures 5 and 6.

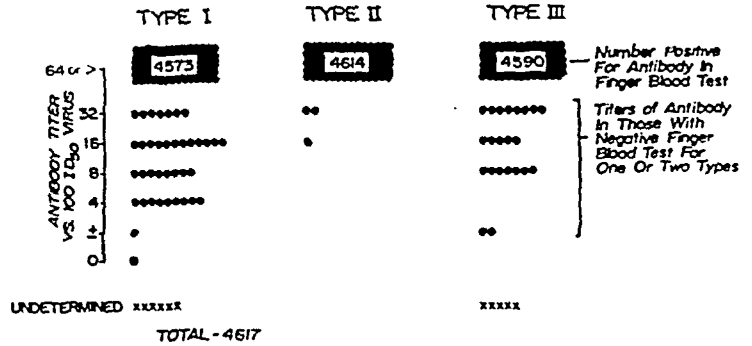

Fig. 8.—Antibody levels determined on samples of venous blood after three doses of vaccine in those who gave negative finger blood test for antibody at level of 1:64.

An effort was made to determine whether the 69 (fig. 7) in whom there was no detectable antibody for one or two types, at the 1:64 level, had antibody at lower levels of detectability. Accordingly, venous blood samples were obtained from all but 11 children: the results are summarized in figure 8. From these data it is clear that the separation of positives and negatives at a level of 1:64, using the finger blood test, greatly simplified the separation of those who needed more detailed study. Thus, a positive test for antibody at a level of 1:64 is indication of the presence of a substantial concentration of serum antibody; but, a negative test does not necessarily indicate that antibody is not present. In fact, in only one instance was antibody not detectable at a level of 1:4. Further investigation and studies are under way to determine the possible reasons for these results or for the low degree of immunologic reactivity, if these observations are confirmed, in all instances, upon retest.

The effect of the three doses in the 847 children (fig. 7) without antibody for any of the three types, at a level of 1:64, is shown in figure 9. It can be seen that there was a reduction to zero in the number with no antibody for any type, but 44 had no antibody, at a level of 1:64, for one or two types. The distribution of antibody titers in these individuals is as shown (fig. 9), and it is seen that antibody was detectable in all but one instance. Since all had responded with good levels to the type 2 component of the vaccine, these findings suggest that the poor responses were not due merely to a low capacity to respond but, also, to differences in relative potencies of the three types.

Effect of One and Two Doses of Vaccine

The advantage of two doses of vaccine, as compared with one dose, in terms of antibody response, is illustrated in figure 10. This shows the degree of response induced in groups of children who had no antibody for any type prior to vaccination and who were given two doses of vaccine four weeks apart. Six lots of commercially prepared vaccine were involved in this study. Titers of antibody were measured four weeks after the first dose and two weeks after the second dose.

In an effort to establish the significance of these measurements, an attempt was made to estimate the degree of correlation between protective effect and immunologic response to one dose of vaccine. Such information could be had from the 1955 epidemic in Massachusetts, caused by the type 1 virus. Studies were made, therefore, of the three lots of vaccine used in Massachusetts in the preceding spring. Children, with no preantibody to any type, were inoculated and antibody levels determined after one and two doses, given four weeks apart. These results are shown in figure 11, where it is seen that the low proportion of response to the first dose was converted to a high proportion by the second dose. It is reported that the protective effect of a single dose against paralytic poliomyelitis in the Massachusetts epidemic was 60 to 65%.[15] This degree of protection is greater than is the percentage response with antibody titers of 1:4 or greater, especially for lot 028849, which was used to a greater extent than the other two.

It should be kept in mind that a negative test for antibody at a 1:4 dilution of serum, according to the serologic method employed, indicates that antibody is not detectable in 0.06 ml. of serum when tested against 100 T. C. I. D.$_{50}$. This is a severe test and does not exclude the possibility that virus neutralizing effect would be demonstrable if a larger volume of serum were allowed to react with the same or a smaller amount of virus. Since it appears that protection may be associated with levels that are too low to be measurable by the test that is employed, it would seem conservative to infer that antibody levels of 1:4 or greater could be expected to be protective.

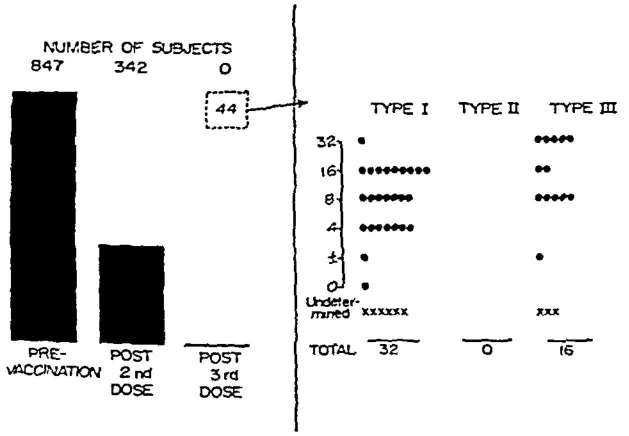

Fig. 9.—*Left*, effect of three doses of vaccine on 847 children with no antibody for all three types at level of 1:64. *Right*, antibody levels determined on samples of venous blood after three doses of vaccine in 44 subjects who have negative finger blood test for antibody at level of 1:64.

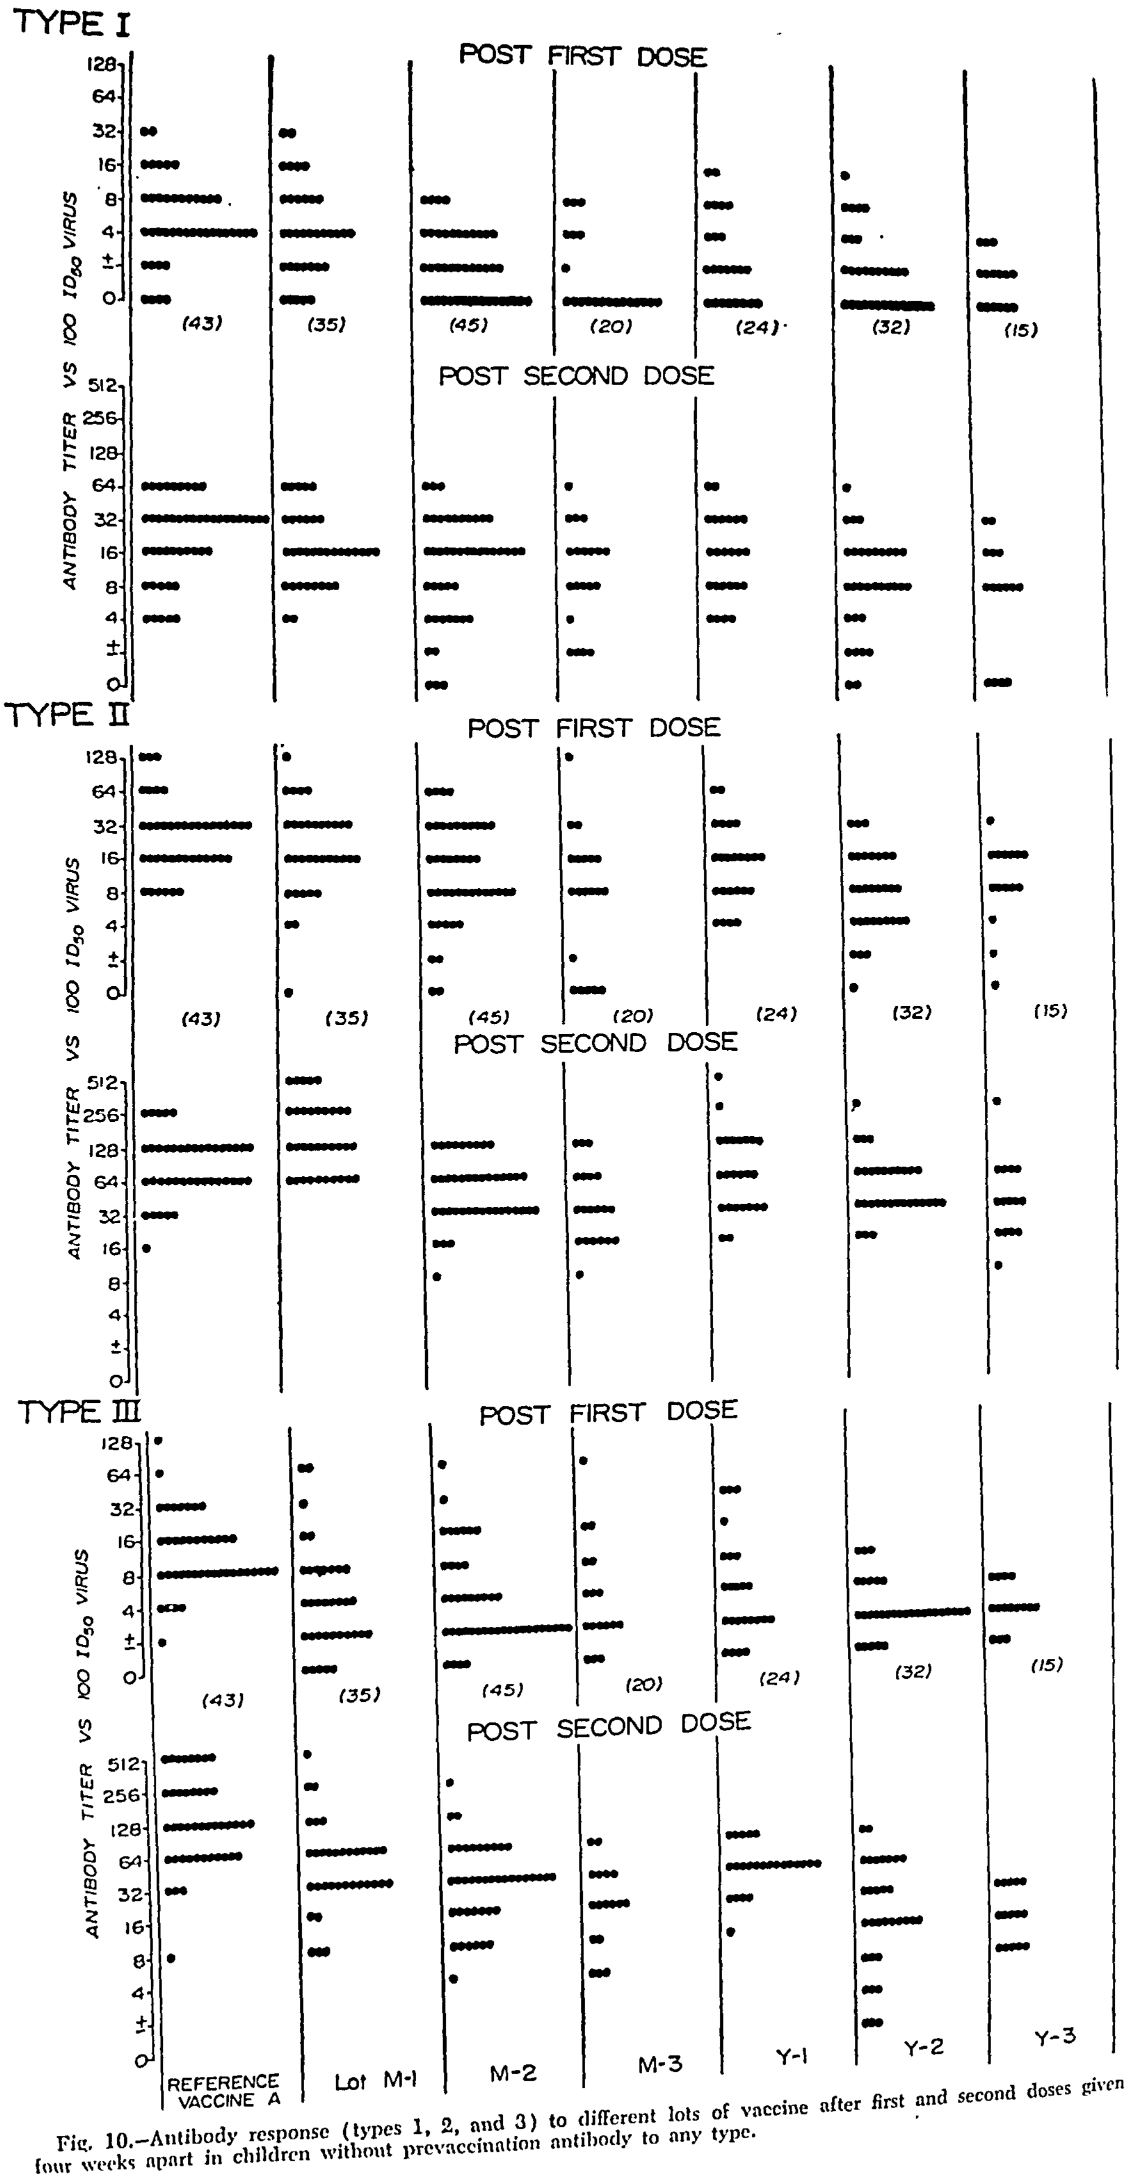

Fig. 10.—Antibody response (types 1, 2, and 3) to different lots of vaccine after first and second doses given four weeks apart in children without prevaccination antibody to any type.

Comment

The objective of these studies was to clarify our understanding sufficiently to permit the establishment of a set of conditions that would, under practical circumstances, produce an effect with a wide margin between the lowest individual response induced and the minimal response that might be required for immunity. In this way it was hoped to approach the irreducible minimum for the number of individuals who fail to respond with a significant degree of immunity.

From these studies it appears that the level of antibody induced, and its degree of persistence, at demonstrable levels, is a function primarily of mass of virus antigen injected, of the number of doses into which this is divided, and of the spacing between doses. The question then arises as to what constitutes adequate antigenic mass and adequate numbers of inoculations. It has been observed, even in individuals who have had minimal antigenic stimulation, and in some intances with no elicitation of antibody response, that there has been induced, nevertheless, a state of hyperreactivity demonstrable by reinoculation after the lapse of a sufficient interval of time. However, from the practical viewpoint of inducing immunity, it would not be reasonable to rely upon the development of immunologic hyperreactivity without the creation, at the same time, of a measurable antibody response. Since the hyperreactivity that develops also seems to persist, if an antibody response was once elicited, it would be more reasonable to aim at inducing the formation of a sufficient level of antibody to be certain that a hyperreactive state has also been created. That a substantial degree of hyperreactivity has been developed may be measured by comparing the degree of antibody response induced after the "booster" with the response to a similar dose of vaccine given to a group of immunologically inexperienced persons. Such effects are demonstrated in figures 3 and 4, which show the distribution of antibody titers before and after a single dose of vaccine J in a group of previously vaccinated persons and in a group not previously treated. The lowest response in the previously sensitized group is equal to or greater than the highest response in the group not previously sensitized.

In the course of these studies, it has been noted not only that that intensity of primary sensitization influences the degree of antibody response but that the booster dose is no more effective than a first injection if the vaccine used in the primary series possessed little or no antigenic activity. This observation was reported earlier and its importance has been mentioned previously. The pertinent findings, shown in figure 12, which illustrate merely a primary response to a so-called booster dose, given 10 months after the primary series, serve as the basis for the recommendation that children who participated in the field trial and who received vaccine that, according to present standards, may have been less than optimal in potency, should receive three doses, as if they had not been vaccinated previously, and that this be administered with intervals suggested by the findings in these investigations. This was discussed in detail in the May 26, 1956, issue of THE JOURNAL.[16]

The questions that confront the physician who administers poliomyelitis virus vaccine are: "How certain am I of the beneficial effects that it is intended to produce? How long will the effect last? Do I have to administer reinoculations and, if so, when? What is the probability that each of my patients individually will escape paralytic poliomyelitis?" These are also questions that are asked by an enlightened public. If the immunologic factors that are operative are understood, patients will more readily cooperate with physicians in the practice of the prevention of this disease, even though this will become more difficult as the fear that is now imposed by the occurrence of epidemics is eliminated.

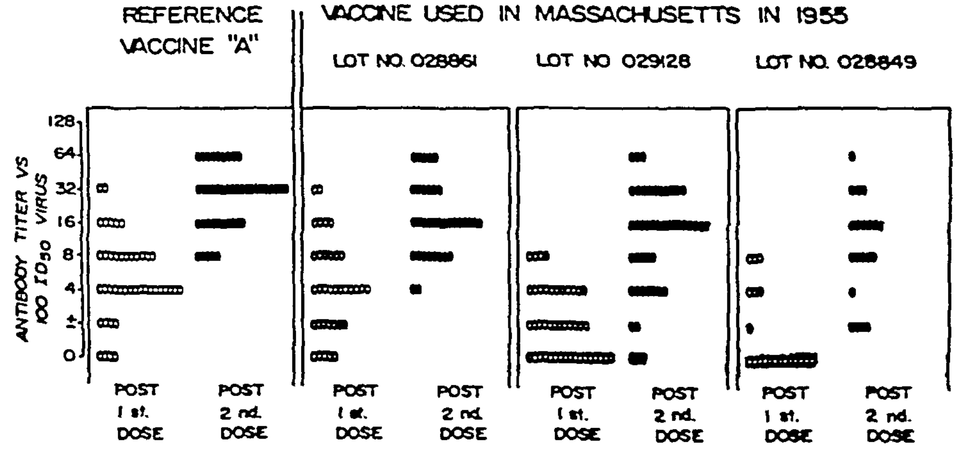

Fig. 11.—Type 1 antibody response after first and second doses of vaccine lots used in the spring of 1955 in Massachusetts.

The answers to the practical questions of consistency of degree of effectiveness and probable duration of immunity are best expressed in terms of the results of studies that were designed to reveal the factors, both quantitative and qualitative, that contribute to variation in individual and in group response. It is clear that the amount of virus antigen injected is the chief determinant of the intensity of the immune response; this is reflected either in level of antibody induced or in degree of immunologic hyperreactivity effected. It has been shown, also, that the amount of virus antigen required to induce a maximal immunologic effect is substantially less if multiple injections are administered and if adequate attention is given to the spacing between inoculations.

Although the efficiency of the effect of multiple injections is greater as the interval between inoculations is prolonged, at least to a certain point, this must be balanced against the desirability of reducing the interval during which the incompletely vaccinated individual is exposed to risk. For this reason, the two primary doses should be spaced not less than two weeks apart, and, during periods of potentially high prevalence, two doses should be given within this short interval. In periods, or regions, of low prevalence, a preferable spacing would be four to six weeks, but may be longer. The third dose, in either case, should be given approximately seven months, or longer, after the second dose, and this interval can be prolonged as long as desired or convenient but should be administered prior to the ensuing seasonal prevalence. A third dose, given some seven months after the primary, not only enhances the level of antibody induced by the primary series but affords a third chance for primary sensitization in the event that the responsiveness of the individual, and the relative potency of the vaccine employed, was such as to have failed to result in a primary response to the first or second doses given earlier.

Thus the schedule of inoculation recommended represents a reasonable compromise, within practical limits, that permits the utilization of the benefits to be derived from repeated inoculation. Moreover, the suggested schedule is intended to provide at least three opportunities for inducing primary sensitization, thereby reducing the practical importance of the factor of individual variation in the ease of development of the immune state. Although a wide latitude exists in the intervals over which inoculations may be spaced, in the route for inoculation and in dosage for an effective response, the factors of critical importance are antigenic mass and adequate spacing of inoculations. In respect to the use of small inoculums intradermally, the evidence is clear that this does not result in effects equal to those achieved with larger doses that can be given by percutaneous routes.

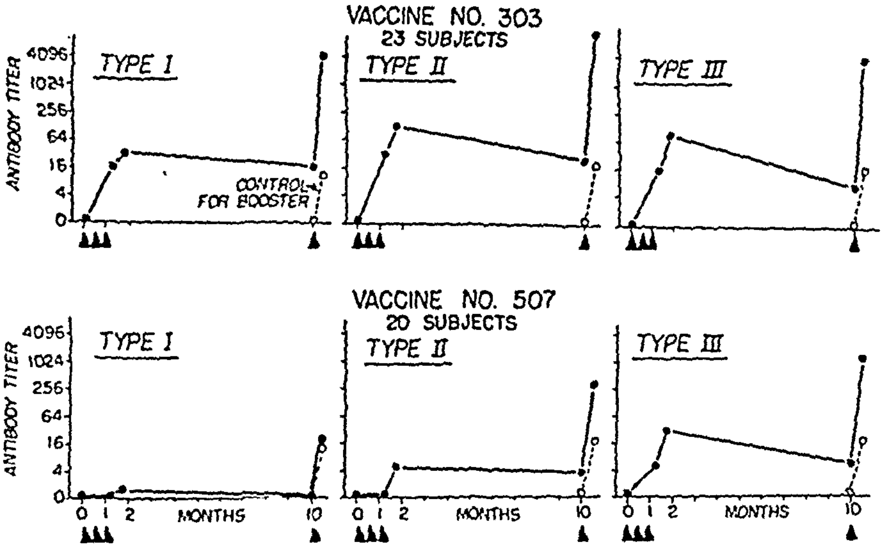

Fig. 12.—Effect of booster dose 10 months after vaccination with two different vaccine lots used in 1954 field tests.

From the evidence at hand, the potency of the vaccine, for each type, could be selected in terms of the effects induced by the different dilutions of reference vaccine A. When vaccines of greater than minimal potency are employed, it should be expected that routine immunization will induce a substantial immunologic effect with a high degree of reliability—even after one dose—and this assurance is increased by a second dose. After the third dose, suitably spaced, the effect should, for practical purposes, be complete. Tests for adequacy of immunizing effect will be continued for the next few years to verify the extent to which this does in fact occur with vaccines of the potencies now available.

The objective of such continued observation is the achievement of a routine of such a degree of consistency that there is built into the immunization procedure a wide "margin of confidence" for effectiveness. Since tests for antigenic potency can be readily made, both in laboratory animals and in children, and since the ultimate requirements for full immunizing effect seem not unrealistic of achievement, it would appear that it is merely a matter of fulfilling these requirements that constitutes the problem that stands between the present and the ultimate elimination of paralytic poliomyelitis. That this can be done, insofar as immunologic measurements can be so interpreted, is suggested by results of tests on children who have received a full course of immunization, with commercially produced vaccine as well as with vaccine produced experimentally.

Although the principal effect of vaccination is to create an immunologic barrier to invasion of the central nervous system, an accessory effect may be the reduction in the degree and duration of virus multiplication at the superficial site of infection. In addition, the establishment of secondary foci of multiplication or excretion might conceivably be prevented, thereby reducing the amount and duration of virus elimination.[13] If hyperimmunization, as tends to occur after secondary stimulation (booster) in those previously vaccinated or previously infected, is influential in creating a state of resistance to infection as well as to the already existent state of resistance to paralysis, then it can be expected that the reservoir of infection will be further reduced.

The concept[17] that some previously infected individuals may be silent reservoirs, serving as intermittent sources of infection, seems to fit best the facts concerning the epidemiologic behavior of this disease. If this be true, then it is conceivable that hyperimmunization, which, if sufficiently great, will limit or prevent the establishment of infection, will also limit or reduce the reservoir of infection by reducing the number, frequency, and duration of carriers in the population. Thus, it could be that vaccination, as it tends to do in other diseases, may bring about a sharper reduction in the amount of paralytic poliomyelitis than is to be expected merely on the basis of the number of individuals vaccinated. That this may well occur is indicated by the reduction, in the summer of 1955, not only in the number of cases of paralytic poliomyelitis but in the number of cases of nonparalytic poliomyelitis in vaccinated as compared with nonvaccinated children, even in those given but one dose of vaccine.[12]

If the mechanism of immunity that has been described is correct, then it is to be expected that the protective effect against paralytic poliomyelitis will be essentially the same during the season immediately following inoculation and during subsequent seasons. This view is based on the indications that, in spite of a tendency for antibody levels to decline, the hyperreactive state appears to persist, and it seems that, through the hyperreactive state, immunity to paralysis may also be mediated. The indications that this mechanism has been operative in vaccinated persons are suggested by the meager evidence that is available that the ratio of cases between vaccinated and controls was essentially unchanged as the 1954 or 1955 seasons progressed, although the tendency for antibody to decline continued during the period in question. Moreover, there has not been any obvious evidence during the summer of 1955 of a reduction in the ratio of effectiveness in those vaccinated in 1954 but not revaccinated in 1955.

Changing epidemiologic patterns will make it difficult to acquire quantitative information on degree of persistence of immunity. Therefore, as a guide to decisions in practice, it is essential to establish and to understand the dynamics both of infection and of immunity in the individual and in the community. The validity of the concepts that have been expressed, of the mechanism of immunity, and of the significance of these concepts will be revealed in time.

Summary

The amount of virus antigen injected is the principal determinant of the intensity of the immune response. This is reflected in the level of antibody induced and/or in the degree of immunologic hyperreactivity effected. Although antibody, at demonstrable levels, tends to persist for long periods, it has also been observed that immunologic hyperreactivity continues, even in those cases in which antibody has declined to nonmeasurable levels. The indications are that immunity to paralysis is mediated not only through existing antibody in the circulating blood but through the mechanism of immunologic hyperreactivity that calls forth antibody sufficiently rapidly, after exposure, to intercept invasion of the central nervous system even though pharyngeal or intestinal infection may have occurred.

This study was aided by a grant from the National Foundation for Infantile Paralysis.

CLINICAL NOTES

REPORT OF TWO CASES OF CARDIAC TAMPONADE IN UREMIC PERICARDITIS

Charles J. Goodner, M.D.
and
Harold Brown, M.D., Salt Lake City

Pericarditis is a frequent complication of uremia in both acute and chronic renal failure.[1] The recognition of uremic pericarditis has been important for three reasons: 1. The onset of pericarditis in uremia has been found to have prognostic significance.[2] 2. Pericarditis is frequently the cause of confusing and distressing pain.[3] 3. Electrocardiographic abnormalities occurring late in uremia are often the result of pericarditis.[4]

Two cases of chronic renal failure, which were seen recently in this hospital, have served to illustrate another significant aspect of uremic pericarditis. In both instances the immediate cause of death was cardiac tamponade, which was a complication of uremic pericarditis. Because of the lack of appreciation of tamponade as a complication of uremic pericarditis in textbooks and the literature, it was thought that a report of these cases would be of interest.

Report of Cases

CASE 1.—A 29-year-old man entered the Salt Lake Veterans Administration Hospital for the second time on Feb. 20, 1953, with weakness and anorexia of one month's duration and the complaint of pain of 10 days' duration in the left shoulder and back.

From the Department of Medicine, University of Utah College of Medicine, and the Veterans Administration Hospital.

BUREAU OF MEDICAL ECONOMIC RESEARCH

PHYSICIAN MORTALITY, 1949-1951

Frank G. Dickinson, Ph.D.
and
Leonard W. Martin, M.A., Chicago

The deaths of 10,738 physicians, 1949 to 1951, relative to a 1950 physician population of 204,450 comprise the basic statistics of this study of physician mortality. Through a detailed examination of these data by age and by cause of death, the highlights of physician mortality experience for the period cited are presented and compared with the mortality experience of white males of the same ages. The presentation of these findings will follow a brief description of the nature of the data and the methods employed in their compilation and development. A more detailed description of the data and methods, along with supplementary tables and the present article, will be presented in Bulletin 103, available from the Bureau of Medical Economic Research, American Medical Association.

Basic Data

The population of 10,738 physician deaths was censused through the use of A. M. A. files and through the procurement of death certificates from state and city departments of health. Without the cooperation of the vital statisticians in these departments, this study would have been impossible. All the deaths were verified by both sources of information except 175 for which death certificates could not be obtained, although these deaths were confirmed by other sources in addition to A. M. A. records. The three-year period during which these deaths occurred was selected for intensive study because it is the most recent for which the National Office of Vital Statistics has tabulated population mortality data for white males, white females, nonwhite males, and nonwhite females.[1]

To be evaluated in terms of mortality experience, the deceased population must be related to its corresponding living population, which is customarily censused on the mid-date of the period under examination. We chose April 1, 1950, for our census of physicians living in the continental United States in order to match the date employed by the National Office of Vital Statistics in computing its life tables. As the result of information received on the death certificates as well as knowledge gained through other checks on the living physician population, a final revised estimate of 204,450 was obtained. In Bureau Bulletin 94, "Distribution of Physicians by Medical Service Areas" (1954), the total was 204,995 for the same date. Both sets of data were derived from the files of the Directory Department, in which almost all the names are those of graduates of approved American and Canadian schools or graduates of other medical schools who were or had been licensed to practice medicine in at least one of the 48 states or the District of Columbia. These refinements of the basic data involving a net reduction of 545 in the living population have, in our opinion, greatly enhanced their quality.

Unfortunately our data on living physicians have two defects. Thus far we have not been able to census the populations of living specialists and so have not examined physician mortality by specialty. We realize, nevertheless, that we are omitting an aspect of physician mortality in which physicians are interested. The second defect is that A. M. A. data do not identify all physicians by sex. Our attempt to determine sex by examining the physician's first name not only resulted in a suspiciously high count of female physicians (10,000) but was proved to be defective; for example, some physicians classified as females by their first names obtained their premedical education in colleges that have never enrolled a female. We were unable, therefore, to determine the population of living female physicians, although we knew the number who died during the three years was 433. It also was not possible to identify physicians by race, although the living nonwhite physicians are known to number between 4,000 and 5,000; very few are females. If the poorer mortality experience of nonwhite males in comparison with white males generally applies also to nonwhite physicians, our inclusion of nonwhite physicians should serve to offset, somewhat at least, the inclusion of females. The extent, however, to which these two compensating factors balance is unknown to us and is recognized as a basic defect in the data. Since 92% of the physicians were white males, white male mortality is used as the basis of comparison in this study.

Valid comparisons between physician and white male mortality experience can be made only when the white male population is adjusted to the age distribution of the physician population. The physician population, unlike the white male population, includes no children. Hence the number dying per thousand could not be used for mortality or cause-of-death comparisons. So 204,450 white males of the same age distribution as the 204,450 physicians is the frame of reference used in this study. Comparisons between these two groups reveal differences in mortality rates only. The procedure commonly employed to make the adjustment is to apply white male death rates by age and by cause to the physician population and to designate the deaths so computed as "expected" deaths, the number that would have occurred among physicians if their mortality experience had been identical to that of white males. Hereafter in this study, unless otherwise indicated, references to white male deaths will be references to these "expected" deaths of a white male population of the same age distribution as the living physician population.

Director (Dr. Dickinson) and Associate in Economics (Mr. Martin), Bureau of Medical Economic Research, American Medical Association, 535 N. Dearborn St., Chicago 10.

Age-Specific Mortality

The analysis of physician mortality experience by age includes death rates by five-year age groups, expectation of life at certain ages, and average ages at death for both physicians and white males. Since mortality rates for all causes by single years of age are available in the life tables for white males, our computations of expected deaths were made for each age, 20 and over. They are tabulated by five-year age groups in table 1 for the sake of parallel presentation with the data on deaths by individual causes to be discussed later. The numbers of deaths among white males by individual causes are available only for five-year age groups.

The Bureau's deck of punch cards was used to determine the ages of the living population. These punch cards, developed over a number of years, show only the year of birth, as does the American Medical Directory. Although information on day and month of birth could be found for many physicians in the files of our Directory Department, it was not practical for the purpose of this study alone to use other than the year of birth. The month and day as well as the year of birth were, of course, reported on the death certificates. We assumed that the births of the living population were evenly distributed throughout the calendar year of birth. In order to determine the attained age as of April 1, 1950, a quarter-year adjustment was necessary and accounts for the quarters (demicals) in the age distribution of the living population by five-year age groups in column (2) of table 1. The age of the dying was the age at the last birthday, and no comparable adjustment of a quarter of a year was required.

The physician deaths during the three years 1949-1951 are shown by age groups in column (3) of table 1. The physician death rates in column (5), however, present the number of deaths per thousand in the age groups during a single year. For example, in the age group 20-24, there were 2,719.75 living physicians as of April 1, 1950, and 12 died during the three-year period 1949-1951. Adjusting the deaths to the number for a single year, instead of the number for three years, the mortality rate (number dying per thousand per year) for this age group was 1.47. For the age group 25-29 the living population on the census date numbered 22,689.50; 75 died during the three-year period under examination, making the death rate for one year 1.10.

Actual Versus Expected Deaths

Whether these physician mortality rates are high or low can best be ascertained by comparing them with the experience for white males. If the 2,719.75 physicians in the age group 20-24 had been subjected to white male mortality experience in 1949-1951, 14.2 deaths [column (4), table 1] could have been expected. The resulting mortality rate then in this age group was 1.74 [column (6)], and the percentage of actual physician deaths to expected was 84.5. In contrast to the experience of white males in terms of the deaths they would have experienced at these ages, physician mortality was 15.5% lower. The expected deaths and the percentage of actual to expected deaths [column (7)] for the five-year age groups are presented in table 1.

Table 1.—*Physician Population as of April, 1950, Deaths and Death Rates, 1949-1951, of Physicians and White Males of the Same Ages, and Percentage of Actual to Expected Deaths*

Age Group (1)	Physician Population, 4/1/50 (2)	Physician Deaths, 1949-1951 (3)	Expected Deaths of White Males, 1949-1951 (4)	Physician Death Rates (5)	White Male Death Rates (6)	Percentage of Actual to Expected Deaths (7)
20-24	2,719.75	12	14.2	1.47	1.74	84.5
25-29	22,689.50	75	116.7	1.10	1.71	64.3
30-34	25,155.75	120	154.2	1.59	2.04	77.8
35-39	27,790.00	165	248.3	1.98	2.98	66.5
40-44	26,706.25	328	383.6	4.09	4.79	85.5
45-49	20,906.25	448	484.9	7.14	7.73	92.4
50-54	17,364.00	599	636.2	11.50	12.21	94.2
55-59	14,372.25	751	819.7	17.42	19.01	91.6
60-64	13,039.00	1,130	1,099.8	28.89	28.12	102.7
65-69	11,742.50	1,458	1,441.1	41.39	40.91	101.2
70-74	10,210.25	1,834	1,857.2	59.87	60.63	98.8
75-79	6,808.75	1,680	1,852.1	82.25	90.67	90.7
80-84	3,447.00	1,268	1,351.5	122.62	133.59	91.8
85-89	1,120.25	580	679.0	172.58	202.04	85.4
90-94	320.00	240	274.9	250.00	286.35	87.3
95-99	54.75	45	64.8	273.97	394.52	69.4
100 and over	3.75	5	5.6	444.44	497.78	89.3
Total	204,450.00	10,738	11,513.8	17.51	18.77	93.3

Whereas 10,738 physicians died during this three-year period, the number of expected deaths would have been 11,513.8. The percentage of actual to expected deaths, therefore, for the entire population was 93.3. The fact that physician deaths were 6.7% fewer than the number that white males of the same ages would have experienced indicates that physician mortality for these three years was definitely lower than that of all white males. (The percentage of actual to expected deaths was 94.7 for a hypothetical white population of 95% males and 5% females at each age, a very rough allowance for our inability to exclude females.) The ratio of actual to expected deaths was lowest for the age group 25-29 (64.3%) and highest for the age groups 60-64 (102.7%) and 65-69 (101.2%). As will be noted later in the discussion of causes of death, the excess mortality of physicians in these two age groups, 60-64 and 65-69, was probably a result of the excess number of physician deaths from diseases of the heart.

Other Comparisons

The complete life table for physicians, together with an account of its computation, will be presented in Bulletin 103; it records the expectation of life for physicians at various ages according to their 1949-

1951 mortality experience. At the start of their careers, physicians have approximately 45 years of life ahead of them. More specifically, the average number of years remaining for physicians according to their 1949-1951 experience was 45.9 at age 25, 44.9 at 26, 36.3 at 35, 23.3 at 50, and 13.0 at 65. The percentage of those alive at selected ages who will reach 70, according to this same experience, was 56.2 for those age 25, 56.8 for those 35, and 58.6 for those 50. Consistent, moreover, with our findings regarding the relationship of actual to expected deaths at various ages, the life table values show a higher expectation of life for physicians than white males at all ages (25 to 102). The smallest difference in life expectancies under age 85 between the two groups was only 0.1 year at age 60, while the greatest was 0.9 year at age 25.

The average ages at death differ little between the two groups. The median age at death for physicians was lower (70.8 versus 71.0 years) but the mean age at death for physicians was higher (68.6 versus 68.4 years). These differences, involving data by five-year age groups, were not statistically significant.

Mortality by Cause

For our analysis of physician deaths by cause, we classified the deaths into 11 groups of leading causes and a residual group, "all other causes." The cause of death categories are defined by using the grouping and code numbers in the Manual of the International Statistical Classification of Diseases, Injuries, and Causes of Death, sixth revision, World Health Organization, 1948. In our study, causes of death were grouped as follows:

1. *Diseases of the Heart* (401, 402.1, 410-443). This group includes rheumatic fever with heart involvement, chorea with heart involvement, chronic rheumatic heart disease, arteriosclerotic and degenerative heart disease including diseases of the coronary arteries, hypertensive heart disease, and other diseases of the heart.
2. *Malignant Neoplasms* (140-205). This group includes all malignant neoplasms classified according to site as well as neoplasms of the lymphatic and hematopoietic tissues. It excludes benign and unspecified neoplasms.
3. *Vascular Lesions Affecting the Central Nervous System* (330-334). This group includes subarachnoid and cerebral hemorrhage, cerebral embolism and thrombosis, and other and ill-defined vascular lesions affecting the central nervous system. It excludes intracranial lesions due to trauma and any condition specified as a late effect, sequela, or death one year or more after onset.
4. *Accidents* (E800-E962). This group includes all transport accidents, accidental poisoning, falls, and other accidental deaths.
5. *Nephritis and Nephrosis* (590-594). This group includes acute, chronic, and unspecified nephritis, nephrosis, and other renal sclerosis.
6. *Influenza and Pneumonia* (480-483, 490-493).
7. *Tuberculosis* (001-019). This group includes all forms of tuberculosis.
8. *Diabetes Mellitus* (260).
9. *General Arteriosclerosis* (450). This group excludes arteriosclerosis with hypertension, and other diseases involving arteriosclerosis.
10. *Cirrhosis of Liver* (581). This group includes cirrhosis of liver with and without mention of alcohol or alcolohism.
11. *Suicide* (E963, E970-E979). This group includes deaths from nonaccidental self-inflicted injuries in suicide or attempted suicide, and excludes accidental self-inflicted injuries.
12. *All Other Deaths.* Our category of "all others" includes deaths from all causes not included in the above major groups.

The number of physician deaths by cause involves decimals as a result of the distribution among the 12 categories of the 175 deaths for which death certificates could not be obtained and for which cause of death was unknown. Only one-sixth of the 10,563 death certificates indicated that autopsies had been performed. We are unable to measure the influence, if any, on our data of better certification of physician deaths. The total number of physician deaths for each leading cause is shown in column (2) of table 2. In order to compare them with the total number of white male deaths, we developed white male death rates by five-year age groups for 1949-1951 from data published by the National Office of Vital Statistics.[2] The procedures employed are described in Bulletin 103. Despite our efforts to match the data used by the National Office of Vital Statistics in computing the life tables, a small discrepancy appears between the total number of expected deaths for all ages by individual causes and the total number of expected deaths for all causes computed for each year of age. The difference is only 16, or 0.1%; this difference would increase the percentage of actual to expected deaths from 93.3 to 93.4. It can be attributed to the smoothing of raw data involved in computing the life tables.

As discovered in earlier studies, we found that by far the largest number of deaths among physicians (and among the general population) were due to diseases of the heart, which accounted for 5,265.6 physician deaths, or 49.0% of the total, and 5,103.3, or 44.4%, of the expected deaths among white males of the same ages. Malignant neoplasms (1,503.9 deaths or 14.3%), vascular lesions affecting the central nervous system (1,201.7 deaths or 11.2%), and accidents (488.6 deaths or 4.6%) ranked second, third, and fourth in the number of deaths for physicians; these three causes also ranked second, third, and fourth for white males. The four leading causes together accounted for 79.0% of physician deaths compared to 75.3% of white male deaths. Each of the remaining causes accounted for only 1.1 to 2.6% of the total deaths. The cardiovascular-renal diseases (groups 1, 3, 5, and 9) accounted for 63.4 and 59.6% of physician and white male deaths respectively. These data and those for the other causes of death are presented in table 2.

Ratio of Actual to Expected Deaths by Cause

The ratio of actual to expected deaths by cause provides a comparison of physician and white male experience that, as in the case of mortality rates above, renders these data more meaningful. These comparisons are shown in table 2. For only three causes—diseases of the heart, diabetes mellitus, and suicide—was there a greater number of deaths than would have been expected in a white male population of the same ages; the percentages of actual to expected deaths were 103.2, 135.1, and 102.8. For each of the eight other causes, mortality experience among physicians in 1949-1951 was more favorable than among white males. In terms of the percentage of actual to expected deaths, physician mortality experience compared most favorably for tuberculosis (119.1 physician deaths), 46.6%, and influenza and pneumonia (160.7 physician deaths), 53.8%. In contrast, the least favorable experience appears to be that for diabetes mellitus (202 physician deaths), with 135.1% of expected deaths.

The difference between the number of physician deaths and the expected number was substantial for a few of the causes. How great a difference is required in order to justify the assertion that mortality among physicians from the named cause of death was significantly different from the mortality among white males? In applying the tests of significance to the differences, we recognize that there is room for more than one opinion. The standard deviation, in percentage, of the ratio of actual to expected deaths from each cause, in percentage, is set forth in column (5) of table 2. Consider the difference for diseases of the heart. Was the 3.2% excess of physician deaths great enough in relation to the standard deviation, 1.4% (1.42), to conclude that mortality from diseases of the heart among physicians was significantly higher than among white males and could not reasonably be attributed to mere chance? The difference is more than twice the standard deviation and almost 2.32 standard deviations, the required difference for 99 chances out of 100—single tail of the normal curve. The difference is also more than 1.64 standard deviations, the required difference for 95 chances out of 100. Those who believe that the difference must be at least 2.32 standard deviations will conclude that the difference in mortality from diseases of the heart among physicians and white males was not quite statistically significant. Those who consider 95 chances out of 100 a sufficient confidence level will contend that the difference in mortality from diseases of the heart among physicians and white males was clearly statistically significant. We conclude that, on balance, physician mortality from diseases of the heart was significantly higher than among white males.

TABLE 2.—*Number and Percentage of Physician and of White Male Deaths, and Ratio of Actual to Expected Deaths, By Cause, 1949-1951*

Cause of Death	Physician Deaths		Expected Deaths of White Males		Percentage of Actual to Expected Deaths	Standard Deviation,* %
	No.	%	No.	%		
(1)	(2)	(2a)	(3)	(3a)	(4)	(5)
1. Diseases of the heart	5,265.6	49.04	5,103.3	44.39	103.2	1.4
2. Malignant neoplasms	1,530.9	14.26	1,649.4	14.35	92.8	2.4
3. Vascular lesions of the central nervous system	1,201.7	11.19	1,247.6	10.85	96.3	2.8
4. Accidents	488.6	4.55	660.6	5.75	74.0	3.3
5. General arteriosclerosis	207.8	1.93	298.4	2.59	69.6	4.8
6. Diabetes mellitus	202.0	1.88	149.5	1.30	135.1	9.5
7. Suicide	190.8	1.78	185.6	1.61	102.8	7.4
8. Influenza and pneumonia	160.7	1.50	298.8	2.60	53.8	4.2
9. Nephritis and nephrosis	131.3	1.22	199.7	1.74	65.7	5.7
10. Cirrhosis of the liver	120.2	1.12	137.2	1.19	87.6	8.0
11. Tuberculosis, all forms	119.1	1.11	255.8	2.22	46.6	4.3
12. All other causes	1,119.3	10.42	1,311.8	11.41	85.3	2.6
Total	10,738.0	100.00	11,497.7	100.00	93.4	0.9

* The standard deviation is the percentage of actual to expected deaths, as shown in column (4), divided by the square root of the actual number of deaths among physicians as shown in column (2). This formula was suggested by Edward A. Lew, Statistician, Metropolitan Life Insurance Company. See also page 11, Impairment Study, 1951, Society of Actuaries, Chicago.

For the other causes of death a choice between 95 chances out of 100 and 99 chances out of 100 is not required. According to the test of 95 chances out of 100—and, of course, 99 out of 100—the differences in mortality among physicians and white males was not significant for vascular lesions affecting the central nervous system, suicide, and cirrhosis of the liver. We conclude, therefore, that the differences noted in the number of deaths and in the ratio of actual to expected deaths among physicians and among white males from these three causes were too small to exclude the possibility that they resulted from mere chance. On the other hand, the differences in mortality between physicians and white males were significant for malignant neoplasms, accidents, general arteriosclerosis, diabetes mellitus, influenza and pneumonia, nephritis and nephrosis, and tuberculosis by the test of 99 chances out of 100. Most important of all, the difference of 6.6 percentage points (100% minus 93.4%) between the mortality of physicians and white males from all causes combined was definitely statistically significant by the test of 99 chances out of 100.

Although diabetes mellitus was a cause for which there were proportionately more physician than expected deaths, it accounted for only 202, or 1.9%, of all physician deaths; the number of expected deaths was only 149.5. The excess, 52.5, was concentrated at the older ages; at ages 60 and over the excess was 54.5, but below age 60 the expected deaths were 2 more than the actual. This fact suggests, but does not prove, greater success by physicians as compared with white males in postponing death from diabetes. Unfortunately, the case rate incidence by age groups for the two populations is not known. The unfavorable experience of physicians from diseases of the heart likewise was concentrated among certain age groups; virtually all the excess deaths, 162.3, occurred at ages 40-74, with approximately 65% of them at ages 60-74.

Other Measures for Evaluating Leading Causes

Further evaluation of the relative importance of the leading causes of death can be made by the use of two additional measures. Rank by numbers of deaths has been employed up to this point in the examination of the ratio of actual to expected deaths. The other two measures are number of life years lost and number of working years lost due to the several causes respectively. In 1949-1951, 10,738 physician deaths, as shown in table 3, resulted in the loss of 132,439 years of life and 39,014 years of working life. Correspondingly, the 11,497.7 expected deaths among white males of the same ages resulted in the loss of 141,791 life years and 45,756 *working life years. These measures* were originally discussed in Bureau Bulletin 64,[3] and their computation for this study will be explained and presented in Bulletin 103.

Life years lost, as a measure of the force of death, impresses upon us forcefully what the loss of life involves. It takes into consideration the age at which the person died and the years he would have lived according to the expectation of life for a person at that age. Such a measure clearly gives added weight to the impact of deaths from those causes that strike the younger members of the population. Working years lost as a related measure attaches even greater weight to the youthfulness of the dying. Being more concerned with the economically productive years of life rather than the whole of life, it additionally minimizes the effect upon the nation's output of goods and services of those deaths from causes whose impact occurs chiefly after age 65. We assigned this age as the terminal point of a person's productive years, although the productive period ends before age 65 for some and after age 65 for others. Accordingly, working life expectancy at ages 65 or over is zero; the years "to be lived after age 65" are excluded in computing working life expectancy, the factor by which the number dying each year under age 65 is multiplied. Comparative data based on age 70, which some may consider a more realistic terminal age, will be presented in Bulletin 103. It should be realized that the higher we designate the terminal productive year, the closer working years lost approximates total life years lost. By designating 65 as this age, we reveal more forcefully which of the causes of death is least severe in inhibiting the potential for production.

In dealing with the physician population and white male experience adjusted to such a population, we must realize that we are considering an adult population. The differences between the ranking by numbers of deaths and those revealed by life years lost and working years lost among such a population would be even more pronounced among a population covering all of the years of life.[3] For convenience, the rankings of the top five leading causes according to the three measures are presented in table 3A, first for physicians and then for white males of the same ages. For physicians, diseases of the heart and malignant neoplasms ranked first and second by all three measures. Vascular lesions affecting the central nervous system ranked third by number and by life years lost, but only fifth by working years lost. Accidents ranked fourth, fourth, and third, whereas suicide ranked seventh, fifth, and fourth. For white males of the same ages, diseases of the heart rank first according to the three measures but accidents displaced malignant neoplasms in second position according to working years lost. Vascular lesions affecting the central nervous system ranked third, fourth, and sixth. Accidents ranked fourth, third, and second; and tuberculosis ranked seventh, fifth, and fourth.

TABLE 3.—*Ranking of Eleven Groups of Leading Causes of Deaths, 1949-1951, of Physicians and of White Males of the Same Ages by Three Measures: Number of Deaths, Life Years Lost, and Working Years Lost*

Cause of Death	No. of Deaths			Life Years Lost			Working Years Lost		
(1)	No. (2)	% (3)	Rank (4)	Years (5)	% (6)	*Rank* (7)	Years (8)	% (9)	*Rank* (10)
					A. Physicians				
1. *Diseases of the heart*	5,265.6	49.04	1	*63,033.4*	*47.60*	1	16,356.2	41.92	1
2. Malignant neoplasms	1,530.9	14.26	2	18,565.4	14.02	2	4,903.1	*12.57*	2
3. Vascular lesions of the central *nervous system*	1,201.7	11.19	3	*11,770.0*	*8.89*	3	1,965.2	5.04	5
4. *Accidents*	488.6	4.55	4	9,051.3	6.83	4	4,824.6	12.37	3
5. General arteriosclerosis	207.8	1.93	5	1,320.4	1.00	11	28.5	.07	11
6. Diabetes mellitus	202.0	1.88	6	2,212.4	1.67	6	451.6	1.16	9
7. *Suicide*	190.8	1.78	7	*4,455.4*	*3.36*	5	2,648.8	6.79	4
8. *Influenza* and pneumonia	160.7	1.50	8	1,575.1	1.19	10	385.9	.99	10
9. Nephritis and nephrosis	131.3	1.22	9	1,620.6	1.22	9	484.9	1.24	8
10. Cirrhosis of the liver	120.2	1.12	*10*	*1,822.2*	*1.38*	8	666.8	1.71	7
11. Tuberculosis, all forms	119.1	1.11	11	*1,974.9*	*1.49*	7	848.2	2.17	6
12. All other causes	1,119.3	10.42	...	15,037.6	11.35	...	5,449.9	13.97	...
Total	10,738.0	100.00		132,438.7	100.00		39,013.7	100.00	
					B. White Males				
1. Diseases of the heart	5,103.3	41.39	1	57,682.2	40.68	1	15,050.1	32.89	1
2. *Malignant neoplasms*	1,649.4	14.35	2	20,635.8	14.55	2	6,080.9	13.29	3
3. *Vascular* lesions of the central nervous system	1,247.6	10.85	3	11,785.6	8.31	4	2,060.4	4.50	6
4. Accidents	660.6	5.75	4	13,659.4	9.63	3	7,963.4	17.40	2
5. General arteriosclerosis	298.4	2.59	6	1,891.9	1.34	10	79.3	.17	11
6. *Diabetes mellitus*	149.5	1.30	10	1,780.4	1.26	11	484.9	1.06	10
7. *Suicide*	185.6	1.61	9	3,831.2	2.70	6	2,102.5	4.60	5
8. Influenza and pneumonia	298.8	2.60	5	3,200.4	2.26	7	923.7	2.02	8
9. Nephritis and nephrosis	199.7	1.74	8	2,509.6	1.77	8	907.9	1.99	9
10. Cirrhosis of the liver	137.2	1.19	11	2,389.1	1.69	9	1,088.8	2.38	7
11. Tuberculosis, all forms	255.8	2.22	7	4,895.8	3.45	5	2,475.7	5.41	4
12. All other causes	1,311.8	11.41	...	*17,529.4*	12.36	...	6,538.7	14.29	...
Total	11,497.7	100.00		141,790.8	100.00		45,756.3	100.00	

Changes in rank as between numbers of deaths and life years lost reflect the added weight given by the latter measure to deaths at earlier ages; changes in rank as between life years lost and working years lost reflect the zero weight given by the latter to deaths at age 65 and over. Higher rank—rank one is highest—for a cause of death according to life years lost and even more so according to working years lost reveals that its incidence is relatively high at the younger ages of life In this manner we can explain the rise in rank for accidents, tuberculosis, and suicides and the fall in rank for vascular lesions affecting the central nervous system and the decline in the percentage importance of diseases of the heart.

These observations apply with the same force to the lesser causes of death as to the major. Among them we find for physicians that not only suicide but also tuberculosis and cirrhosis of the liver shift to a higher rank in life years lost than in mere numbers of deaths, and, as between life years and working years lost, nephritis also moves up in rank. Conversely, general arteriosclerosis and pneumonia shift downward respectively to the last and next to the last positions for both life and working years lost. Even diabetes mellitus drops from sixth in numbers and life years lost to ninth in working years lost. Since the extra deaths among physicians from diabetes mellitus occurred at ages 60 and over, it is not surprising that white males lost a greater number of working years from diabetes mellitus than did physicians. The direction of movement in rank among causes so far as these measures are concerned was the same for white males as for physicians with but two exceptions: for physicians nephritis was higher and diabetes lower in working years lost than in life years lost, but the shifts were just the opposite for white males.

TABLE 3A.—*Ranking of Five Leading Causes of Death for Physicians and White Males*

Cause of Death	By No of Deaths	By Life Years Lost	By Working Years Lost
A Physicians			
Diseases of the heart	1	1	1
Malignant neoplasms	2	2	2
Vascular lesions	3	3	5
Accidents	4	4	3
Suicide	7	5	4
B White Males of the Same Ages			
Diseases of the heart	1	1	1
Malignant neoplasms	2	2	3
Vascular lesions	3	4	6
Accidents	4	3	2
Tuberculosis	7	5	4

The relative positions of the causes as between physicians and white males were changed little in shifting from one measure to another It is true that accidents moved ahead of malignant neoplasms for white males in working years lost and general arteriosclerosis fell to last place for physicians in life years lost. The higher rank for suicide and diabetes among physicians than white males, however, prevailed for all three measures, just as the higher rank for pneumonia and tuberculosis did among white males. Moreover, diseases of the heart and malignant neoplasms in this adult population accounted for almost the same percentages of totals according to all three measures

Some Historical Comparisons

The death rates for 10-year age groups (age 25 and over) developed by Emerson and Hughes[4] for 1925, applied to our age distribution of living physicians in 1950, produce 12,842 deaths, or 16 5% more than the reported total of 10,726 (excluding 12 deaths below age 25) in 1949-1951. Similar computations with the age-specific rates for 10-year age groups developed by Dublin and Spiegelman[5] for 1938-1942 produce 12,394 deaths, or 13 5% in excess of the 10,726 deaths in 1949-1951. These differences roughly measure the improvement in physician mortality since 1925.

Using the age-specific mortality rates among white males for 1920 applied to the age distribution of white male physicians in 1925, Emerson and Hughes found an excess in the number of deaths among white males. For the period 1938-1942, Dublin and Spiegelman found that the number of deaths among male physicians slightly exceeded the number of deaths expected among white males of the same ages. Our present study for 1949-1951, like the 1925 study and unlike the 1938-1942 study, found an excess in the number of deaths among white males of the same ages as our physician population. The differences in techniques and our belief that our source data are superior to those in the two preceding studies of physician mortality make us hesitant to conclude that the relationship between the number of physician deaths and the number of deaths among white males of the same ages has undergone any substantial change since 1925 or since 1940.

Moreover, age-specific mortality rates for white male physicians were lower than those for white males in 1925, and slightly higher (for male physicians) in 1938-1942, as already noted in this study, the rates (for all physicians) were slightly lower in 1949-1951. Physician death rates in these three studies have compared most favorably with those of white males at the younger ages (25-34 and 25-44) and least favorably within the broad age group 45-64. For the most recent period examined, 1949-1951, we found the physician experience poorer than that for white males at ages 60-69 Certain other comparisons for these two previous studies are suggestive but not conclusive.

Experience with respect to expectation of life is similar to that for death rates. For physicians the expectation of life at age 30 rose from 38 0 years in 1925[6] to 41.0 years in 1950, for white males the corresponding average number of years of life remaining were 37 6 and 40 3. The physician at age 50 had on the average 21.7 years remaining in 1925 and 23 2 in 1950, white males had 21.7 in 1925 and 22 8 in 1950 More generally, physician expectation of life was lower than that of white males in 1925 at the ages over 50, and in 1938-1942 between the ages of 25 and 70, and the excess for physicians was least in 1949-1951 at age 60.

Unfortunately, groupings of physician deaths by causes for the purpose of comparing our study with the two previous studies is hazardous because of revisions in the international list of the causes of deaths that were made between 1925 and 1940 and between 1940 and 1950. We made a considerable number of computations for the purpose of producing such historical comparisons by groups of causes The comparisons did indicate that in 1938-1942 there were several groups of causes for which physician deaths exceeded expected deaths among white males of the same ages, whereas in 1949-1951 there were only three such causes.

Summary

An examination of the death certificates of more than 10,000 physicians who died during the period 1949-1951 in relation to the population of living physicians as of April 1, 1950, revealed that the number of physician deaths was only 93 3% of the number of deaths that would have been expected if physicians had experienced the age-specific mortality rates of white males. Physician mortality experience was better than that for white males in all except two of the five-year age groups and for 8 of the 11 groups of leading causes. It was poorer in the age groups 60-64 and 65-69 and for diseases of the heart, diabetes mellitus, and suicide; for the first two of these three causes, the differences were statistically significant. Although the expectation of life at all ages was greater for physicians than for white males, differences in the median and mean ages at death were not significant. Diseases of the heart clearly comprised the leading cause of death for both physicians and white males according to all three measures—numbers of deaths, life years lost, and working years lost. Unfortunately, separate mortality tables could not be developed for the several speciality groups and for females.

COUNCIL ON FOODS AND NUTRITION

Report to the Council

The following comments on fats in the diet are based on a speech given at the Margarine All-Industry Conference, Hot Springs, Va., May 24, 1956. The Council has authorized publication of this report.

PHILIP L. WHITE, SC.D., *Secretary.*

FATS IN THE DIET IN RELATION TO ARTERIOSCLEROSIS

Charles D. May, M.D., Iowa City

Current research on the causes of arteriosclerosis and coronary heart disease at least encourages an optimistic outlook. Recent findings indicate that these conditions may be acquired diseases rather than inevitable consequences of the aging process. Considerable evidence is being accumulated that these conditions, which are most common in some of the more highly civilized populations and appear to be increasing in prevalence, may be in large measure a result of faulty nutrition. A spirit of hopefulness has been aroused that this scourge may be prevented or checked by appropriate regulation of the diet.

It is imperative that the urgency in the situation not be allowed to disrupt a sound and orderly attack on the problem, through exploitation by selfish interests or undue emotion and competitiveness among investigators. A prime need is for conservative, deliberate, and cautious interpretation and application of the fragments of knowledge seemingly related to the solution of these problems. When knowledge seems sufficiently certain to justify application, great caution must be exercised in manipulating the diets of populations lest unanticipated deficiencies or imbalances are created. Interesting but unproved leads must not be made the basis of dietary recommendations.

The focal point of interest at present is the role of dietary fat. Dietary fat is not a single, simple substance but is a complex mixture of fats, steroids, lipid-soluble pigments, and other substances. Some of the fatty acids are essential for certain animals and possibly for the health of the human species and should be supplied in the diet. A certain amount of fat in the diet is required to make it palatable and satisfying. Fats from the various animal and vegetable sources differ in their composition. Nutritionally, a major recognized difference is the relative amounts of so-called essential fatty acids.

For some time there have been indications that the total amount of fat consumed bears some relation to the amount of a fatty substance, cholesterol, that accumulates in the blood. In turn, the cholesterol in the blood has been thought to have some part in the causation of arteriosclerosis and coronary heart disease. High levels of fat in the diet and high levels of cholesterol in the blood have commonly been held responsible for the increasing incidence of these conditions in certain populations that habitually consume diets containing an abundance of fat.

In this connection, it now appears that a distinction must be made between fats from the usual animal sources and the majority of fats of vegetable origin. Recent studies in man and in experimental animals suggest that saturated fatty acids may lead to greater accumulation of cholesterol in the blood than a corresponding amount of unsaturated fatty acids. Unprocessed vegetable fats include larger amounts of the so-called essential unsaturated fatty acids than do most animal fats; the significance of this difference in preventing or relieving the accumulation of excessive amounts of cholesterol in the blood is the subject of intensive investigation at present.

Attention should be focused on the amounts of saturated and unsaturated fats in the diet rather than on the total amounts of fats, whether of vegetable or animal origin. The ratio between the amounts of "essential" unsaturated fatty acids and the saturated fatty

---

Chairman, Department of Pediatrics, College of Medicine, State University of Iowa.

acids may be the crucial consideration. An actual deficiency of the so-called essential unsaturated fatty acids severe enough to cause the signs and symptoms observed in animals, but not in man, may not be prevalent; however a relative insufficiency of "essential" unsaturated fatty acids may be important in the pathogenesis of arteriosclerosis. The metabolism of the load of saturated fatty acids imposed by the more abundant fat in the diets of some populations may require the simultaneous provision of larger amounts of "essential" unsaturated fatty acids than are required to deal with diets containing relatively small amounts of saturated fatty acids, whether of animal or vegetable origin.

Besides fat, many other factors such as sex, heredity, age, physical activity, other dietary deficiencies, total amount of calories ingested, and disorders of the liver and kidney influence the amount of cholesterol in the blood. It is not likely that a single cause will be found responsible for all cases of arteriosclerosis, nor should expectation be aroused that this condition will be completely prevented or regularly checked by a mere altering of the kind or amount of fat in the diet. The extent to which the findings in experimental animals can be applied to the disease state in man is by no means certain.

It is easy to assume that obesity is the result of eating too much fat, but this is not strictly true. The body is able to convert other foodstuffs such as carbohydrate into fat. The ingestion of an excessive amount of calories or energy-producing food leads to obesity. It is generally easier and safer for a person to reduce his weight on a diet containing the usual proportion of fat but restricted in total calories because the appetite is better satisfied with a diet containing fat. The problem of obesity is separate from the determination of the proper use of fat in the diet for the promotion of sound nutrition.

The need for caution in setting arbitrary levels for the amounts of animal or vegetable fats in the diet is made apparent when one considers the paucity of pertinent knowledge on the role of fat and the constituent variety of fatty acids in human nutrition. It is obviously unwise and unnecessary to exclude fats from the diet, and even if desirable would no doubt be virtually impossible. Estimations of total fat consumed by populations with differing incidences of arteriosclerosis are too crude to serve as more than a guide for planned investigations. Only a clue as to the qualitative and quantitative significance of unsaturated versus saturated fatty acids has been gained from epidemiological surveys.

The present situation demands that the public receive guidance from competent physicians in the interpretation of the exciting but fragmentary knowledge that seems to bear upon the problems of arteriosclerosis and coronary heart disease. Exploitation of incomplete knowledge by industries for the purpose of competition or by investigators for personal recognition would be irresponsible and detrimental to progress in conquering these major afflictions. Everyone concerned will benefit from any aid that can be given to research directed at basic knowledge of these diseases or to predisposing disturbances in metabolism within the individual, even though the immediate application may not be apparent.

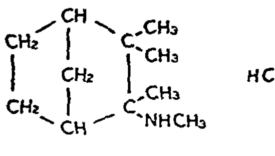
COUNCIL ON PHARMACY AND CHEMISTRY

NEW AND NONOFFICIAL REMEDIES

Monographs and supplemental statements on drugs described here and in subsequent editions of New and Nonofficial Remedies are based on the evaluation of available scientific data and reports of investigations. Applicable commercial names for preparations of evaluated drugs are listed at the end of monographs and parenthetically in the text of supplemental statements; additional commercial names of which the Council is informed will be included with subsequently published supplemental statements and annual editions of New and Nonofficial Remedies.

H. D. Kautz, M.D., *Secretary.*

Mecamylamine Hydrochloride.—3-Methylaminoisocamphane hydrochloride.—The structural formula of mecamylamine hydrochloride may be represented as follows:



Actions and Uses.—Mecamylamine hydrochloride, a secondary amine, exerts a powerful inhibitory effect on the transmission of impulses at autonomic ganglions. Although it is not a quaternary ammonium compound, its ganglionic blocking action is almost identical to that of hexamethonium; therefore, the drug effects a decrease in blood pressure in both normotensive and hypertensive subjects. Unlike hexamethonium, mecamylamine hydrochloride is almost completely absorbed from the gastrointestinal tract and is effective by the oral route. Because it is more uniformly absorbed than hexamethonium, fluctuations in gastrointestinal activity, such as diarrhea and constipation, do not produce so great a variation in hypotensive effectiveness with oral dosage. The drug exerts a longer duration of action than does hexamethonium, and equivalent reduction in blood pressure may be achieved with a lower dose. Since the onset of action is more gradual than that with hexamethonium, the incidence of sudden drops in blood pressure is appreciably reduced. As with all ganglionic blocking agents, prolonged administration leads to decreased effectiveness. This tolerance is not as pronounced with mecamylamine as with hexamethonium and is somewhat less than that observed after therapy with pentolinium tartrate. Cross tolerance between mecamylamine and the other ganglionic blocking agents has not been observed.

In general, the indications for therapy with mecamylamine hydrochloride are the same as those for other ganglionic blocking agents. Thus, the drug may be employed for the treatment of moderate to severe hypertension; it is sometimes successful in arresting the malignant phase of hypertension. Because of the unpleasant nature of side-effects that frequently accompany therapy with ganglionic blocking agents, the use of mecamylamine should generally be reserved for those patients with the more severe forms of hypertension who have not responded adequately to milder drugs such as the Rauwolfia alkaloids. It should never be used in patients with mild or labile hypertension. When employed under carefully controlled conditions with adequate attention to proper regulation of dosage, mecamylamine may be expected to reduce blood pressure effectively and to ameliorate various manifestations of hypertensive-cardiovascular disease. These include such symptoms as headache, dizziness and vertigo, hypertensive encephalopathy and cerebral or subarachnoid hemorrhage, retinopathy, cardiac hypertrophy, and, in some cases, cardiac decompensation. Although the drug may be of benefit in some hypertensive patients with angina pectoris, care should be exercised in its administration, since in other patients it may exacerbate anginal attacks or precipitate myocardial infarction in the presence of coronary insufficiency.

For the treatment of the more severe types of hypertension, mecamylamine can be employed in conjunction with reserpine. Such combination therapy may sometimes produce a more intense antihypertensive effect than can be obtained with mecamylamine alone. In addition, this regimen allows for a lower total dosage of mecamylamine, with a consequent lessening in the side-effects attributable to ganglionic blockade.

Like all agents of this class, mecamylamine hydrochloride is capable of producing a variety of unpleasant side-effects referable to inhibition of both sympathetic and parasympathetic nervous systems. Dryness of the mouth, visual disturbances, constipation preceded by diarrhea, urinary retention, anorexia, nausea and vomiting, weakness and fatigue, sedation, interference with sex functions, dizziness, syncope, and paresthesias have been observed in patients undergoing therapy with this drug. Patients should likewise be warned about the occurrence of orthostatic (postural) hypotension. Extreme care must be exercised with regard to bowel function, since the constipation that frequently accompanies therapy with mecamylamine can proceed into paralytic ileus. To avoid this serious complication, some physicians advise routine concomitant administration of laxatives; however, all patients should be advised to discontinue hypotensive therapy immediately if abdominal distention, decreased borborygmi, or other signs of bowel stasis become evident. In such cases, intensive cathartic therapy is indicated; cholinergic agents, such as neostigmine methylsulfate or bethanechol chloride, may be used to treat impending or frank ileus and urinary retention. In poor-risk patients with malignant hypertension and azotemia or other signs of renal insufficiency, often in association with cerebral atherosclerosis, the administration of large doses may rarely produce tremor or mental aberrations, such as delusions or hallucinations.

Mecamylamine hydrochloride has not been studied for sufficiently long periods to determine with certainty the frequency and severity of all side-effects as compared with those of other ganglionic blocking agents. On the basis of current evidence, it would appear that these are no more troublesome than those with other agents of this class and that some reactions, notably impairment of vision, are less in number and severity than those caused by hexamethonium.

Contraindications to the use of mecamylamine hydrochloride are the same as those for other ganglionic blocking agents. These include such conditions as severe coronary insufficiency, recent myocardial infarction, retinal and cerebral thrombosis, and any other disorder characterized by severe reduction of blood flow to a vital organ. The drug should be administered with caution to patients with renal insufficiency. Rapid, excessive reduction in blood pressure is also dangerous in patients with severe and generalized atherosclerosis. If necessary, pressor amines may be administered to combat excessive hypotensive effects; however, since many patients under therapy with ganglionic blocking agents are more reactive than normal to pressor amines, dosage must be reduced accordingly. Since the drug blocks the normal vasoconstrictor hemostatic mechanisms, its use is contraindicated in any situation in which there is a large reduction in blood volume. Mecamylamine hydrochloride is contraindicated also in the presence of glaucoma, organic pyloric stenosis, and uremia.

Dosage.—Mecamylamine hydrochloride is administered orally. Dosage is highly individualized according to the severity of the hypertension and the response of the patient. The latter varies greatly. Ideally, dosage should be adjusted to the point where desired blood pressure can be maintained without the appearance of severe side-effects. This situation is not always easily attainable. In addition to great variations in individual susceptibility, other factors, such as excessive heat, fever, infection, hemorrhage, pregnancy, antihypertensive or other drugs, alcohol, vigorous exercise, surgery, and anesthesia, alter the hypotensive response. Excessive salt loss, such as that occurring after diarrhea, vomiting, and mercurial diuresis, increases the hypotensive effect of the drug and necessitates reduction in dosage. Diurnal variations in blood pressure require administration of lower doses in the morning than those given in the afternoon and evening. Seasonal variations also alter the hypotensive effect of mecamylamine, larger doses being required in the winter months than in the summer. It should also be remembered that ordinarily a smaller reduction in blood pressure is produced by the drug when the patient is in a supine or sitting position; therefore, dosage should be determined on the basis of blood pressure readings made with the patient in the standing position. Since frequent standing blood pressure recordings under basal conditions afford the best method for accurate dosage adjustment, these are best carried out in the home by the patient or a member of the family.

Therapy is initiated by the administration of 2.5 mg. twice daily. This dosage is then increased by increments of 2.5 mg. at intervals of not less than two days until the desired blood pressure response has been obtained. The average daily dose required for maintenance is about 25 mg. in three divided doses. Individual susceptibility to the drug is so great that as little as 1 mg. may mean the difference between tolerable and intolerable side-effects.

Applicable commercial name: Inversine Hydrochloride.

Merck Sharp & Dohme Research Laboratories, Division of Merck & Co., Inc., cooperated by furnishing scientific data to aid in the evaluation of mecamylamine hydrochloride.

COUNCIL ON MEDICAL PHYSICS

Report of the Council

The Council has authorized publication of the following report.

Ralph E. DeForest, M.D., *Secretary.*

PROGRAM OF THE COUNCIL ON MEDICAL PHYSICS

The Council on Medical Physics, a standing committee of the Board of Trustees of the American Medical Association, is composed of 13 members from various fields of medicine and the basic sciences. The members were chosen because of the special knowledge that they have, and not as representatives of specialties. The Council was created by the Board of Trustees in accordance with the actions of the House of Delegates at the Clinical Meeting in Boston, Nov. 29-Dec. 2, 1955,[1] and at the Annual Meeting in Chicago, June 11-15, 1956.[2]

The purpose of the Council on Medical Physics is to encourage an understanding of the actions and rational uses of apparatus and physical methods employed in the study of the human body and its functions, notably the diagnosis, treatment, and prevention of disease. Since the physical methods used in medicine are explained in terms of the sciences of physics, biophysics, and medicine, the Council was named Council on Medical Physics. In pursuit of this purpose, the Council program will consist of the evaluation of classes of apparatus and physical methods, the encouragement of research, and the performance of such other services within its purview that may be assigned by the Board of Trustees or decided upon by the Council.

Apparatus and Physical Methods Evaluation.—The Council evaluates, when desirable, new, previously considered, or established classes of physical methods and apparatus intended for the diagnosis, treatment, and prevention of disease. The evaluation statements contain, where applicable, the principles, actions, uses, contraindications, and appropriate safety warnings regarding the use of the class of apparatus or physical method being reported upon. These reports are submitted to the Editor of The Journal for publication in the Council column.

The Council's evaluation statements are prepared after consideration of scientific clinical and laboratory evidence concerning a class of apparatus or a method and after consideration of other available evidence, including published and unpublished reports. The Council obtains opinions from experts in the field who serve as consultants. The Council itself does not conduct clinical or laboratory tests, experiments, or research in evaluating apparatus or physical methods.

It is important to note that the Council does not consider individual brands of apparatus but reports only on general classes of apparatus. Occasionally, a device made by only one manufacturer may constitute a new idea or method of treatment. In this instance, although the device name and model will not be mentioned, the general principles employed in any such class of apparatus will be discussed. No endorsement or guarantee of any specific brands of apparatus is intended or implied.

The Council decides whether to undertake the evaluation of the evidence pertaining to a class of medical apparatus or physical method. Manufacturers are encouraged to cooperate with the Council by providing data and information, including scientific laboratory and clinical evidence (published and unpublished reports), regarding the usefulness, safety, actions, mode of operation of, and contraindications for their apparatus, if it falls within a class the Council has voted to evaluate. Before compiling and providing any such data and information for the Council, the manufacturer should contact the Secretary of the Council on Medical Physics, American Medical Association, 535 N. Dearborn St., Chicago 10, Ill., to determine whether the Council is considering, or will consider, the evaluation of the evidence relating to that particular class of product.

All available evidence, including the opinions of the Council consultants on such evidence, is submitted to a Council referee. The referee makes his recommendations regarding the evaluation report, which may be prepared either by the Council staff or by an author designated by the Council. This report, together with the referee's recommendation, consultants' comments, and copies of the available evidence, is provided to all the Council members for consideration. The proposed evaluation report is then reviewed and revised in accordance with the comments of the members. After adoption by vote of the Council, a copy of the report will be sent for comment to known manufacturers. Comments and criticisms received from the manufacturers are considered before the report is sent to the Editor of The Journal for publication.

As another activity, the Council will compile informative articles on the role of physical agents and methods in the care of patients with specific diseases, as well as such articles in general and special areas of medical practice.

Encouragement of Research.—The Council desires to encourage needed research on practical problems involving apparatus and methods falling within the scope of medical physics. The Council does not finance research or conduct clinical and laboratory projects itself. The Council plans to point out areas in which research is needed and will attempt to facilitate the development of sound investigative programs leading to the production of scientific evidence necessary in evaluating the usefulness of clinical devices, apparatus, and instruments. The value of such evidence is apparent to the manufacturer and the profession.

Progress by the medical profession in the application to medicine of new contributions from all branches of physics and engineering is proceeding at an ever-increasing rate. New devices and the new methods they employ are in many instances unfamiliar to most practitioners. An appreciation of the actions and rational uses of these apparatus and methods is desirable if the best interest of the patient is to be served. The Council intends, through its program, to provide a useful and valuable information service to the profession.

MEDICINE AT WORK

DOCTOR, TAKE THE STAND

Almost unnoticed, two great professions—medicine and law—are teaming up in a new public service effort that promises to save the taxpayers millions of dollars a year.

Director C. Joseph Stetler of the American Medical Association's Law Department was concentrating not on taxes but on a legal point nearly two years ago during his summer vacation. His point was that, with medical testimony figuring as key evidence in about three out of every four court actions, the doctor and the lawyer should get to know one another's work a little better. His point was that many doctors were not doing their best on the witness stand, often because just as many lawyers were not doing their best in bringing out enough clear medical evidence. Stetler's point was that this lack of rapport was impeding the administration of justice.

Invariably in situations of this sort, the suffering is felt most deeply not by the physician or attorney but by the general public—ranging from the plaintiff or defendant whose case is not presented fairly to the unrelated man on the street who must foot most of the bill for the trial.

So Stetler carried on a policy begun back in 1914 when the A. M. A. House of Delegates voted acceptance of a three-year survey report pointing up the important role of the physician as a medical witness. (That policy also set the stage for closer doctor-lawyer cooperation outside the courtroom, such as the creation of a joint committee on narcotics addiction and joint conferences on chemical tests for motorist intoxication.)

Stetler wrote a skit illustrating the boners pulled by both physicians and attorneys in a hypothetical court case. Here, the doctor is useless to a railroad man trying to collect damages for a permanent back injury. The physician shows himself as a bungling amateur. He is unprepared with records, slipshod in memory, and so verbose in terms not understood by the jury that he sounds like an ancient medical textbook. This spectacle, coupled with a skillful defense presentation, is all the "reasonable doubt" that the suspicious jury needs to decide against awarding damages for the injured man.

Proper Presentation

In the second half of this before-and-after story, both the physician and the injured man's lawyer are so well-prepared (with the doctor using a shadow box to illuminate x-rays and the attorney expressing his familiarity with medical examination methods) that the jury easily understands what is being presented.

That skit had its première before an audience of 300 at a medicolegal symposium in Chicago Oct. 9, 1955. Aside from making medical matters clearer to attorneys, and vice versa, the session accomplished something equally important. It had doctors and lawyers regarding each other with new respect. The symposium idea began spreading across the country, often bringing together both professions for the first time in their community's history. Such was the case in Peoria, Ill., recently, where 300 physicians and attorneys assembled in a somewhat cagey atmosphere.

Then they viewed the play, viewed each other's viewpoints of the performance, and very much liked what they saw. It was a heartening occasion.

The one-hour play has been enacted successfully for the two professions at meetings in a dozen cities—including New York, Omaha, Denver, Fort Wayne, Ind., Atlanta, Ga., and Des Moines, Iowa. There were three presentations before state medical association houses of delegates and one for a comparable bar association body. At least three more performances are scheduled in coming weeks. Several local groups, impressed with the response at regional meetings, have written similar scripts of their own.

By late fall, Stetler decided that the demand called for reaching a relatively mass market in medicine and law. So the A. M. A. and the American Bar Association, in cooperation with a Cincinnati pharmaceutical house, the Wm. S. Merrell Company, produced a 35-minute film version of the play in the New York City studios of Dynamic Films, Inc. Shooting on the script took one week, and "The Medical Witness" was premièred last Nov. 27 at the A. M. A. Clinical Session in Seattle for hundreds of physicians and attorneys. There was such interest in the film that two showings were needed to accommodate standing-room audiences.

This week the motion picture is being made available without charge, through the A. M. A. film library, to law and medical societies and schools across the nation. It is the first in a series of six movies on medicine and the law.

Really, it is for the interest of all. For example, in New York City each day of a trial costs the taxpayers at least $750. The average trial lasts about three days, for a total of $2,250. So it is readily apparent that expert medical testimony in its fairest sense—when applied to the heavily congested court calls of New York, Chicago, Detroit, Philadelphia, Los Angeles, and many other cities—not only would reduce the number of trial days but also would result in the settlement of cases prior to the trial stage.

Large Dollar Sign

What attorney would risk the possibility of losing a questionably proved case when he is reasonably certain of an effective medicolegal counterattack? Expand that picture to cover the multitude of cases on file throughout the land and the view is bound to focus on a large dollar sign: millions of dollars saved annually.

Certainly, the gains to justice through closer liaison between doctors and lawyers are more than monetary. Another benefit lies in greater public respect for both professions, resulting in increased confidence generally in the administration of justice and in medical practice. This, in turn, would tend to encourage expert testimony from many physicians who in the past have recoiled in disgust at two sights: the ignorant and corrupt medical man who hires himself out as a partisan for one side or the other, and the lawyer who fosters it by calling for a wrongful slant on medical testimony.

As A. M. A. President Dwight H. Murray put it last August at an American Bar Association meeting in Dallas: "I am convinced that the major portion of the difficulty with medical expert testimony stems from the minority of cases wherein the system is not so much at fault as are the men—of your profession and mine—who pervert the system to their selfish ends."

Both the A. M. A. and the A. B. A. believe that medicolegal skulduggery in the courts is the exception rather than the rule. More common is the case in which a perfectly honest and sincere doctor and lawyer unintentionally bring about a miscarriage of justice through improper or confused presentation of the facts. When evidence is presented thoroughly and accurately so that a just decision can be made, the doctor-witness and the lawyers for both sides find themselves speaking the same language.

Who can say what unforeseen additional benefits may accrue from this growing tendency of physicians and lawyers to join in the quest for justice—not through being forced together by legislation, but by the more solidifying experience of voluntary cooperation? The doctor, more than any other professional man, is called as a key witness in court actions. Perhaps his greater accord with men of law will set a clear pattern for experts in other arts and sciences who often are handicapped within their own specialties when they are called upon for evidence.

Meanwhile, uppermost now in this new and sweeping doctor-lawyer rapport is the promise of less abuse and deficiency in the field of expert medical testimony. It can mean less delay from the fantastic pileup of pending damage suits, increased knowledge of their own and one another's range of endeavor, and the prospect of future accord in all matters of mutual interest for the welfare of their fellow man.

Left, in this scene from the motion picture "The Medical Witness," the physician on the stand tries to illustrate his testimony with an x-ray film that would be unclear to the jurors even if the lawyer were not blocking their view.

Center, a shadow box is used to illuminate a diagnostic finding from the same x-ray picture—so that the jury can see the basis of the expert medical testimony in the same case.

Right, Dr. David B. Allman, A. M. A. President-Elect (left), joins with president David F. Maxwell of the American Bar Association in presenting the new medicolegal film "The Medical Witness" at the A. M. A. Clinical Session in Seattle.

BLOOD GROUP PARADOXES

GUEST EDITORIAL

Alexander S. Wiener, M.D.
and
Irving B. Wexler, M.D.

Up to a decade ago, descriptions of clinical investigations frequently suffered from a failure to apply statistical methods. Investigators have since become so sensitized to the value of biometrics that nowadays rarely does an article appear without its standard errors and chi squares duly recorded. Unfortunately, at the same time there has been a tendency to overlook the fact that mathematics is no substitute for common sense. If the premise from which an investigation starts is false and the observations inaccurate, even the most painstaking calculations will lead to erroneous conclusions. A possible example of this is provided by the recent epidemic of articles dealing with the distribution of the blood groups in various diseases.

More than 20 years ago studies on the distribution of the ABO blood groups in disease enjoyed considerable vogue. At that time, the blood groups were studied in such conditions as dementia precox, malaria, general paresis, migraine, epilepsy, longevity, various skin diseases, bone and joint tuberculosis, dental caries, susceptibility to poliomyelitis, and many other conditions. However, whenever a supposed cor-

the disease and predominately brown-eyed, it would be found that in a random sampling of the entire population relatively more people with brown eyes would have the disease. This explanation rarely had to be invoked, however, since in most of the cases the real difficulty proved to be faulty methods of collecting the data. Eventually, workers in the field realized the inherent fallacies in these studies, and it was accepted that the ABO groups had no effect on health, except in hemolytic disease of the newborn infant, where isosensitization of the mother provided a logical explanation. Recently, however, investigations of this type have been resumed on a large scale.

During the past few years, reports have been published purporting to show an association between blood groups and such conditions as duodenal ulcer, gastric carcinoma, pulmonary cancer, rheumatic fever, sarcoidosis, diabetes mellitus, pernicious anemia, fertility, pituitary adenomas, fractured femurs, Dupuytren's contracture, bronchiectasis, portal cirrhosis, bronchopneumonia in childhood, arteriosclerosis, and hypertension. In some cases the technique of blood typing is suspect, as in the report that claimed that every one of 28 patients with Dupuytren's contracture belonged to type Rh_1Rh_2. In one of the newer studies reporting an association between duodenal ulcer and group O, a study that is made impressive by virtue of the large size of the series involved, the controls consisted of tens of thousands of blood donors typed within a short period of time in a blood donor center, while the experimental group was culled from the records of many hospitals over a period of several years. This difference in the method of compiling the data in the two series may have introduced a bias into the results. Significantly, when instead of using random donors as controls the relatives of affected individuals were used to make up the control series, the supposed correlation between blood group O and duodenal ulcer could not be confirmed.

Also of interest is a recent report claiming a supposed association between carcinoma of the body of the stomach and blood group O. In the control series of 30,000 blood donors, 48.9% proved to be of blood group O, while, among 225 patients with carcinoma of the body of the stomach, as many as 68.4% belonged to group O. These 225 were part of a larger series of 483 individuals, all of whom had carcinoma of the stomach, the difference being made up of two groups no great significance is ordinarily attached to differences far greater than have been observed in most of the studies on blood groups in disease.

One wonders how many readers who may have been impressed by the reported association between blood group A and fractured femur have pondered the possible pathway through which one's blood group could influence the occurrence of a fracture. Before too much energy is expended on such an exercise, let the thoughtful clinician remember that the hardest things to explain are those that are not true.

THE GENERAL PRACTITIONER'S AWARD

In accordance with the now well-established practice, the House of Delegates of the American Medical Association, on November 27, at the 10th Clinical Meeting in Seattle, named Dr. Edward M. Gans of Harlowton, Mont., the General Practitioner of the Year. The gold medal, designed especially to go with the award and to honor a general practitioner who has rendered exceptional service to his community, has been given annually since 1948. Dr. Gans, who has practiced medicine for 51 years, has practiced for 44 years in the Harlowton area. He was born December 27, 1875, at St. Cloud, Minn., and was graduated from the University of Minnesota Medical School in 1905. After an internship spent in the city of Duluth, Dr. Gans moved to Eveleth in Minnesota's famous iron mountain country, where he practiced for six years, then moved on to Dickinson, N. D., for one year, and in 1912 moved on to Judith Gap near Harlowton.

Edward M. Gans, M.D.

Always interested in community affairs, Dr. Gans was first health officer and then was elected mayor of Judith Gap, which position he left in 1917 to serve as a captain in the United States Army Medical Corps in France during World War I. After the war he returned to practice medicine in Judith Gap until 1929 and then moved to Harlowton. Dr. Gans was president of the Montana Medical Association in 1930, and in 1955 he became eligible and was made a member of that association's Fifty Year Club. He is one of the few physicians who has been in active practice in Montana for 50 years. Now 81 years of age, he is still active in the practice of medicine.

Dr. Gans has two sons following in his footsteps. The older, Dr. Paul Gans, is practicing in Lewistown, Mont., and the younger, Dr. Edward Gans, is practicing otolaryngology in Oakland, Calif.

The nine physicians who have received the General Practitioner award since the first was chosen in 1948 are Archer Chester Sudan, Kremmling, Colo.; the late William L. Pressly, Due West, S. C.; Andy Hall, Mount Vernon, Ill.; the late Dean Sherwood Luce, Canton, Mass.; Albert C. Yoder, Goshen, Ind.; John M. Travis, Jacksonville, Texas; the late Joseph I. Greenwell, New Haven, Ky.; Karl B. Pace, Greenville, N. C.; and E. Roger Samuel, Mount Carmel, Pa.

ANNUAL CONGRESS ON INDUSTRIAL HEALTH

The year 1957 will mark a milestone in the history of the Council on Industrial Health, which will have completed 20 years of work in striving to make occupational health programs serve more effectively in complementing the services of clinical medicine and community health. Its program has evolved over the past 20 years from one of limited interests to one in which it has assumed leadership in a number of fields, particularly in the improvement of communication and cooperation between management, labor, the medical professions, and other groups concerned with employee health. One of the activities of the Council on Industrial Health is the Annual Congress on Industrial Health, which has become a nationally recognized medical forum. The wide range of discussions in previous annual meetings reflect both its interests and the current issues and problems that are of present-day concern to all those involved in maintaining high standards of occupational health.

The 17th Annual Congress on Industrial Health, to be held in Los Angeles, February 4-6, 1957, with its theme of "Spotlight on Burns-Vision-Pesticides-Noise" reveals one aspect of the Council's work. The technical discussions to be presented in connection with such topics as Vision in Industry, Health Hazards of Agricultural Chemicals, New Concepts in the Management of Burns, and New Developments in Hearing Loss due to Industrial Noise are demonstrations of the type of program and information the Council seeks to disseminate to the widest extent possible. The sessions planned will present new and hitherto unpublished data surrounding various developments in these fields of inquiry. The congress participants are acknowledged leaders in their fields, and their contributions will stimulate discussion and further inquiry for the medical and allied professions.

The detailed program of the forthcoming Annual Congress on Industrial Health (this issue, page 1478) speaks well for a highly rewarding meeting. The program spotlights more than a group of important discussions; it focuses attention on the kind of activity the American Medical Association encourages and stimulates in its quest to protect the health of the American worker.

ORGANIZATION SECTION

ADDRESS OF THE PRESIDENT

Dwight H. Murray, M.D.

Almost six months have elapsed since we last met to deliberate and act on medical affairs. The time has passed quickly, but not quietly. The rumble of war and revolution has resounded in our ears. The din from political battles has been deafening.

All of us—sooner or later—learn that today's events do not just swirl around us, but involve each of us. As doctors we cannot get away from them by claiming that our only interest is in the sick and that we cannot be bothered by political, social, and economic problems. These matters demand attention from the doctor as well as the lawyer, the businessman, the newspaper editor, the labor leader, and the worker.

If we are concerned about what happens on the international, national, and local fronts—and we should be—then certainly we cannot afford to be disinterested in what happens in our own area of health and medical affairs. Yet there is apathy in our ranks.

Replace Apathy with Active, United Profession

Today there is a greater need for a united, forceful, and informed profession than ever before. We have been caught in the throes of a social revolution which demanded something for nothing. Changes have been taking place all around us, and medicine has not escaped unscathed. For example, in a few days Public Law 569, the bill providing medical care for military dependents, becomes effective throughout the land. Contracts already have been signed with the government by the majority of our state societies. No longer can any doctor claim that this law does not affect him. No longer can he say that government laws really are not changing the practice of medicine.

Public Law 880, better known to all of us as H.R. 7225, is another case in point. Medicine now is facing the problem of protecting the taxpaying public from abuses and of cooperating with the government to carry out the provisions of the law. The law is now on the books, and we must provide the leadership necessary to make it work as well as possible.

It was encouraging to hear Ezra Taft Benson, Secretary of Agriculture, say last week before the American Association of Land Grant Colleges and Universities:

> Sooner or later, the accumulation of power in a central government leads to a loss of freedom. . . . Raids on the federal treasury can be all too readily accomplished by an organized few over the feeble protests of an apathetic majority. With more and more activity centered in the federal government, the relationship between the cost and the benefits of government programs becomes obscure. What follows is the voting of public money without having to accept direct local responsibility for higher taxes. . . . If the present shift of power from state to federal authority which started 25 years ago is allowed to continue, the states may be left hollow shells.

It was encouraging to hear such comments from a member of the President's Cabinet. I only wish that all members of the official family and, more important every member of the United States Congress felt the same way.

The expression of this philosophy, with which medicine so heartily agrees, sounds good, but putting it into practice is the thing we are really interested in.

Today the medical profession along with business and industry is caught between those who desire to promote sound government and those who desire even more intensely to perpetuate party power. Unfortunately, in recent years a benevolent federal government appears more attractive to the voting public than the preservation of individual freedom. Medicine must do its utmost to reverse this trend.

Medical Freedom Essential

In my travels around the country as your representative the last 18 months, I have seen little dissension or rancor within our ranks. However, I must report that I have seen too much complacency over governmental encroachment into medical affairs. And I am deadly serious when I say to you that apathy by the few, or by the many, can be detrimental to all.

No nation can merely reap the benefits of freedom; it also must sow seeds of freedom. In medicine the situation is the same. If an apathetic medical profession takes its freedom for granted, it will be the beginning of the end. A strong, free profession must work for freedom so that it may live in freedom. And history tells us that once medicine loses its freedom, other fields of private endeavor are immediately in danger.

I do not wish to paint a dark or distorted picture of medicine's free status and its stature in America today. But I do believe words of caution and an appeal for vigilance are in order. The road of apathy and disunity can lead only to disorder and perhaps disintegration, and we must sound a warning to all our colleagues who do not care, or who are pulling in the opposite direction. The road of alertness, action, and unity is the proper road for all of us to be traveling together.

If I had just one wish for the coming year, it would be to command the time and talents of the 160,000 physicians in the American Medical Association. I would set us all to the task of emphasizing and re-emphasizing the absolute necessity of patient and professional freedom.

Patient's Right to Choose His Doctor

I believe it is one of our prime responsibilities to prove to our patients that their right to choose their doctor is a most important one. Free choice brings a bond of confidence between doctor and patient which no compulsory medical system can create. It means that the patient knows the physician will be interested in him as a person, not as just a serial number of the 2:45 appendicitis case.

Read before the House of Delegates at the 10th Clinical Meeting of the American Medical Association, Seattle, Nov. 27, 1956.

For the doctor free choice means that the patient has selected him for his abilities, training, sincerity, and personality. When a patient comes into my office, I know he has made a choice. And from that moment there begins a physician-patient relationship of the highest order. To me the patient is someone special, and I in turn hope I am someone special to him.

Once the patient has made his choice, the physician automatically assumes an unqualified responsibility to the patient. No system of medical care that uses a third party to bring doctor and patient together can match our kind of cooperative performance for the treatment of illness, the cure of disease, and the betterment of the patient's health.

Freedom to select a doctor is part of everyone's great freedom to choose—to choose what he wears and eats, where he works and worships, and how he votes. Take away any part of this freedom and great damage is done to our democratic system.

Free Conduct in Medical Treatment

Another freedom closely tied to freedom of choice is freedom in the conduct of medical treatment. At the recent meeting of the World Medical Association in Havana, Cuba, Dr. Rolf Schloegell of Germany made a stirring defense of free conduct of medical treatment. He told us that the medical profession believes the attending physician alone is competent to decide what measures he deems necessary and will apply in order to bring about the desired improvement. He warned too of the danger of excessive restriction on the freedom of the patient and the attending doctor.

Yet the trend toward extending social security in the medical care field has been steady and has accelerated since the end of World War II. The dangers of shifting responsibilities for medical care from the patient and doctor to the government are obvious. The caliber of medical care cannot be as high when both patient and doctor are dependent upon government. Initiative succumbs to dictation, and self-reliance is replaced by the crutch of government.

We do not deny that there is an area of legitimate concern by the government for the health and welfare of the people. But each year government seems to extend that area. We get some idea of this expansion from the new federal medical budget. This year, according to our Washington Office, the average family will be paying $54.61 for the U. S. government's health and medical activities. And the total expenditures this year amount to 2.5 billion dollars—290 millions more than last year. Even in an over-all federal budget of 61 billion dollars, the total health cost of 2.5 billions is not insignificant. It is a billion dollars more than the cost of running the Commerce Department, half a billion more than that of running the Agriculture Department, and six times more than the Interior Department's budget.

Many expenditures obviously are necessary to keep up our unsurpassed public health standards, and research may pay rich dividends in scientific discoveries. But there is no doubt that much money is being spent on medical activities that should not involve government participation.

The trend is to spend more and more government money on health and medical matters because it is good politics. Apparently many Americans still want to see government in the role of a big brother, dishing out so-called gifts and bargains under the guise of benevolent economic planning.

I believe it is our duty, as it is everyone else's, to combat the attitude of "what's in it for me?" and to promote the long-honored creed of "what's best for all Americans and our free society?" I think that a nation can drift into state medicine inch by inch just as surely as if the scheme were foisted upon a people overnight. The "drift" method may take longer, but the result will be the same.

So it is time all of us sounded the alarm against soft and superficial security and against the invasion of personal responsibility. It is time we stood up together for militant freedom and for full rights and responsibilities of the individual.

Belgian Doctors Turn Back Government

There is no better example of what a unified medical profession can do than in the story of the recent fight of the Belgian doctors against the government's proposals for a state service of medicine.

Without consulting the medical profession the Belgian government proceeded to draft rules and regulations of health to be incorporated in the nation's social security legislation. Under the proposals doctors were to sign an agreement to abide by the present rules and any later regulations. For the patient there would be the usual red tape in getting medical care.

When the Belgian doctors learned of the scheme, they met in conference with the government. They told the government what they wanted and what they would not accept. The government agreed. For several months everything was quiet. Then the Belgian doctors suddenly read about the new health bill that the government was sending to Parliament. It was quite contrary to the earlier agreement worked out by the profession and the government. But the bill was passed quickly.

The Belgian medical profession protested and said it would not be placed under the Ministry of Labor. Instead the doctors proposed to set up their own plan of medical assistance. Before long, the government saw that the medical profession meant business and that the doctors' plan was an attractive one. So it declared that its own bill was not in force and could not be in force without the consent of the medical profession.

To me this fight against legislative intervention in medical care is excellent evidence that the profession can defend itself if it unites to defend the basic principles of freedom and if it offers constructive proposals. By using the Belgian national motto, "in union there is strength," the medical profession showed doctors everywhere that dangerous government plans can be turned aside by the strong.

I also read recently in the journal of the World Medical Association of the fight of the medical profession of Malta against a British government scheme to introduce a full-time salaried medical service, without the right of private practice, on an island dependency of Malta. Here again the doctors reacted with unity and strength, and successfully thwarted the government's plan.

There is a lesson in these stories from Belgium and Malta. They prove that a unified profession has a great political power for good—the good of the patient, the doctors, and the nation.

Confidence of Patients, Understanding of Legislators Needed

While we are developing unity within our own ranks, I believe it is equally important to continue to build up the confidence and respect of our patients, and to make our legislators aware of the necessity for freedom in medical practice.

Let us never reduce the quality of service we render to our patients, and never lose the personal touch in medicine. Where there is any opportunity to improve upon our medical care, let us seize it and show our abilities to do an outstanding job. Satisfied patient-customers will give us deserving support when we need it.

We also should realize that the destiny of medicine can be determined to a large degree in the halls of Congress. If this be true, then it is even more important that we take an even greater interest in those who elect the congressmen. Sympathetic understanding of our position by federal legislators through the voting public will be an insurmountable deterrent to the forces supporting state medicine.

The day has come, gentlemen, when we can no longer look upon medical economics and social changes merely as issues to be considered during our limited leisure hours. Our interest in them cannot be superficial or intermittent. We now must pay daily attention to these matters. Medical socioeconomic affairs can no longer be just incidental with us. They must be a vital part of our life and of our profession.

Each of us, I believe, should dedicate himself to the words included in the oath of office taken by the President of the A. M. A.: "I shall champion the cause of freedom in medical practice and freedom for all my fellow Americans."

As doctors, representatives to the A. M. A., and spokesmen for the A. M. A., let us remember these words and live by them. And to alter a phrase of President Lincoln's only slightly: Let's make common cause to keep the good ship of medical freedom on this voyage, or nobody will have a chance to pilot her on another voyage.

ANNUAL CONGRESS ON INDUSTRIAL HEALTH

"SPOTLIGHT ON VISION-PESTICIDES-NOISE-BURNS"

Co-sponsors:
California Medical Association
Los Angeles County Medical Association
Northwest Association of Occupational Medicine
Western Industrial Medical Association

The Council on Industrial Health of the American Medical Association announces the following details regarding the 17th Annual Congress on Industrial Health, to be held at the Biltmore Hotel in Los Angeles, Feb. 4, 5, and 6, 1957. The technical discussions and scientific exhibits are open to all physicians, nurses, industrial hygienists, engineers, and others interested in occupational health. There is no registration fee.

VISION IN INDUSTRY

A Comprehensive Examination of Fundamentals and Fine Points

PRESENTED IN COOPERATION WITH THE NATIONAL SOCIETY FOR THE PREVENTION OF BLINDNESS

PART I

Monday, Feb. 4, 2 p. m.
Chairman—FRANKLIN M. FOOTE, M.D., New York
Components of a Complete Vision Program
FRANKLIN M. FOOTE, M.D., New York
A Critical Evaluation of Vision Screening Methods
MICHAEL J. HOGAN, M.D., San Francisco
Testing for Color Perception
DEAN FARNSWORTH, New London, Conn.
Estimation of Loss of Visual Efficiency
EDMUND B. SPAETH, M.D., Philadelphia
Relationships Between Illumination and Vision
H. RICHARD BLACKWELL, Ph.D., Ann Arbor, Mich.

PART II

Tuesday, Feb. 5, 9 a. m.
Chairman—EDMUND B. SPAETH, M.D., Philadelphia
Responsibilities and Limitations of the Industrial Nurse in the Vision Program
MARGARET HARGREAVES, R.N., New York
Elements of a Successful Eye Protection Program
JAMES E. O'NEIL, New York
RICHARD WILKINS, Los Angeles
The Prescription Safety Goggle Problem
E. J. SCHOWALTER, M.D., Chicago
Emergency Treatment of Chemical Injuries to the Eye
RALPH RYAN, M.D., Morgantown, W. Va.
Screening for Eye Disease
FRANKLIN M. FOOTE, M.D., New York

HEALTH HAZARDS OF AGRICULTURAL CHEMICALS

Tuesday, Feb. 5, 2 p. m.
Co-Chairmen—LEMUEL C. MCGEE, M.D., Wilmington, Del.
RUTHERFORD T. JOHNSTONE, M.D., Los Angeles
Agricultural Chemicals—Economic Facts, Laws and Regulations
ALLEN LEMON, M.D., Sacramento, Calif.
The Phosphorous-Containing Insecticides—Toxicology, Clinical Symptoms and Treatment
H. H. GOLZ, M.D., New York
The Chlorinated Organic Insecticides—Toxicology, Clinical Symptoms and Treatment
FRANK A. PRINCI, M.D., Cincinnati
Control of Hazards in the Use of Agricultural Chemicals—California Experience
ROBERT L. METCALF, M.D., Riverside, Calif.

BANQUET

(Informal)

Tuesday, Feb. 5, 7 p. m.
Presiding—WILLIAM P. SHEPARD, M.D., New York
Presentation of Award of the President's Committee on Employment of the Physically Handicapped
Address
DWIGHT H. MURRAY, M.D.
President, American Medical Association
Address
ERNEST B. HOWARD, M.D.
Assistant Secretary, American Medical Association

NEW CONCEPTS IN THE MANAGEMENT OF BURNS

Wednesday, Feb. 6, 9 a. m.
Chairman—PAUL S. RICHARDS, M.D., Salt Lake City
Brief Historical Résumé of the Subject
PAUL S. RICHARDS, M.D., Salt Lake City
Dry Aluminum Powder Therapy for Thermal Burns
M. D. MAXMEN, M.D., Toronto, Canada
The Exposure Method of Treatment
GEORGE T. VAN PETTEN, commander
Medical Corps, U. S. Navy, Newport, R. I.

Research in the Treatment of Burns
Robert D. Pillsbury, Lieut. Col., Medical Corps, Surgical Research Unit, Brooke Army Medical Center, Fort Sam Houston, Texas
Oral Treatment of Burn Shock
Kehl Markley, M.D., Philadelphia

NEW DEVELOPMENTS IN HEARING LOSS DUE TO INDUSTRIAL NOISE

Presented in cooperation with the
Subcommittee on Noise in Industry,
Committee on Conservation of Hearing,
American Academy of Ophthalmology and
Otolaryngology

Wednesday, Feb. 6, 2 p. m.
Chairman—James H. Sterner, M.D., Rochester, N. Y.
Methods for Conservation of Hearing
Howard P. House, M.D., Los Angeles
Status of Research Activities of the Subcommittee on Noise in Industry
Aram Glorig, M.D., Los Angeles
What Constitutes Disability and How Is It Measured
Hallowell Davis, M.D., St. Louis
Allowable Noise Exposure for Hearing Conservation
Walter A. Rosenblith, Boston
Teamwork Solution of the Industrial Noise Problem—Successful Coordination of the Activities of the Medical Director, the Consulting Otologist, the Industrial Hygienist, the Audiometric Technician, the Safety Engineer, the Supervisory Staff, the Plant Engineer, the Personnel Director, and others
Paul J. Whitaker, M.D., Milwaukee

The Scientific Exhibits will include a number directly related to the technical discussions:

Treatment of Burns
Burn Management in the USS Bennington Disaster
Phosphate Ester Insecticides
Pesticides
Accidental Poisoning in Children
Testing for Eye Disease
Demonstrations of Vision Testing Devices
Speech Audiometry
Automatic Audiometry
Multiple Audiometry
Research in Noise

Special tours of the research laboratories of the Subcommittee on Noise in Industry are scheduled for Monday, Feb. 4, at 10 a. m. and 8 p.m., and Thursday, Feb. 7, at 10 a. m. Advance reservations are desirable due to limitations on the size of the group that can be accommodated.

A hospitality committee will assist sightseeing visitors in planning trips to points of interest such as Disneyland, Farmers' Market, Old Mexico in Olvera Street, the Old Spanish Missions, Catalina, Knott's Berry Farm and Ghost Town, the Huntington Library and Art Galley, and famous restaurants. Regular tour service will also be available.

WORLD MEDICAL ASSOCIATION ELECTS OFFICERS

At its 10th General Assembly held in Havana, Cuba, Oct. 9-15, 1956, the World Medical Association elected the following officers:

President—1956-1957
Dr. Jose A. Bustamente, Cuba
President-Elect—1956-1957
Dr. Ahmet Rasim Onat, Turkey
Treasurer—1956-1959
Dr. Ernst Fromm, Germany
Members of Council—1956-1959
Dr. Gunnar Gundersen, U. S. A.
Dr. Marcel Poumailloux, France
Dr. S. C. Sen, India
Dr. Lorenzo Garcia-Tornel, Spain

The Council of The World Medical Association elected the following officers for the coming year:

Chairman of Council
Dr. Lorenzo Garcia-Tornel, Spain
Vice-Chairman of Council
Dr. L. R. Mallen, Australia

The Officers of Committees for 1956-1957 include:

Editorial Board
Dr. Austin Smith (U. S. A.), Chairman
International Liaison
Dr. Jean Maystre (Switzerland), Chairman
Medical Education
Sir Lionel Whitby (U. K.), Chairman
Medical Ethics
Dr. P. Glorieux (Belgium), Chairman
Miscellaneous Business
Dr. Otto Rasmussen (Denmark), Chairman
Planning and Finance
Dr. T. C. Routley (Canada), Chairman
Social Security
Dr. Dag Knutson (Sweden), Chairman
Dr. Rolf Schloegell (Germany), Secretary

The Council appointed the following officers:

Regional Secretaries
Asia—Dr. S. C. Sen, India
Australasia—Dr. John Hunter, Australia
Europe—Dr. Paul Cibrie, France
Latin America—Dr. Hector Rodriguez H., Chile
World Medical Journal Officials
Dr. Austin Smith (U. S. A.), Executive Editor
Dr. Stanley S. B. Gilder (Canada), Associate Editor
Dr. Louis H. Bauer (U. S. A.), Business Manager
Liaison Officers
Dr. Jean Maystre, Switzerland
Dr. P. Glorieux, Belgium
Dr. V. A. Fenger, Denmark

The New Zealand Branch of the British Medical Association was elected to membership in the World Medical Association at the 10th General Assembly. This association was organized in 1896 and has approximately 810 members.

The following are among numerous resolutions adopted by the 10th General Assembly of the World Medical Association:

International Medical Law

"It is the primary function of the medical doctors of the world to formulate any code of International Medical Law and The World Medical Association is the only organization that can speak for the doctors of the world."

Traffic Accidents

"Whereas: The death and maiming of humanity throughout the world is increasing rapidly each year; and

"Whereas: It is the duty and responsibility of the medical profession in every country of the world to assist in the preservation and maintenance of human life;

"Therefore, be it resolved: That The World Medical Association recommend to its member associations that they cooperate with other agencies and authorities within their country to whatever degree is possible and necessary in a concentrated endeavor to save and preserve human life."

MEDICAL NEWS

ALABAMA

Public Health Physicians Needed.—According to the *Journal of the Medical Association of the State of Alabama*, a critical shortage of public health physicians exists in that state. Health officers are employed under three classifications, according to standards set by the state merit system: health officer 1, $500-$700 a month; health officer 2, $600-$800 a month; and health officer 3, $700-$900 a month. The applicant should be under 60 years of age, in good health, licensed or eligible for licensure to practice in Alabama, and a member or eligible for membership in a county medical society. Information may be obtained from the State Health Officer, 501 Dexter Ave., Montgomery 4.

Evacuation Hospital in Training.—The 109th Evacuation Hospital of Birmingham, Alabama National Guard, has returned from two weeks of training at Fort McClellan near Anniston. Under the command of Col. Samuel R. Terhune, the hospital gave medical support to the nondivisional units of the Alabama National Guard in training at Fort McClellan and concurrently conducted sectional training. The following section chiefs assisted: Lieut. Col. Jo R. Hood, Birmingham, chief of surgery; Lieut. Col. James G. Wood Jr., chief of x-ray; Lieut. Col. Howard F. Pringle Jr., D.D.S., Mobile, chief of dental section; Major John T. Strickland, Birmingham, chief of medicine; Major Thomas H. Williams Jr., Montgomery, urologist; captains Frederick H. DeVane and James C. Denton, Birmingham, orthopedic surgeons; and Capt. Daniel T. Meadows, D.D.S., Birmingham, dental surgeon.

CALIFORNIA

Cancer Mortality.—According to the Los Angeles County branch of the American Cancer Society, cancer claimed the lives of 7,381 men, women, and children in Los Angeles County in 1955, eight times as many deaths as the 952 fatalities from automobile accidents.

Proposed Stanford Medical Center.—Former President Herbert Hoover, honorary chairman of the Stanford Medical Center Fund, recently announced the establishment of the fund and its "first stage" objective, to raise $21,950,000 for development of a medical center on the university campus at Palo Alto. The goal includes 1 million dollars for improving the present Stanford University Hospital in San Francisco. For the new medical center a group of three-story buildings is projected, connected by open walkways on all levels and including a 215-bed teaching hospital, clinics, teaching facilities, and a library. The buildings, to be erected on a 40-acre campus site at a cost of $14,450,000, will comprise about 525,000 sq. ft. Endowment funds of $6,500,000 plus the 1 million dollars for remodeling of the present Stanford hospital, comprise the total stage-one goal of $21,950,000.

Funds already available total nearly 4 million dollars, including gifts and bequests of about 2 million dollars and over $500,000 from state and federal agencies to help construct a rehabilitation center unit. A grant of 1 million dollars from the Commonwealth Fund of New York is also included in the sum on hand, although it actually will not be received until matched by gifts from West Coast donors. A long-term stage-two fund-raising effort of equal magnitude, to be made following completion of stage one, will finance further development of the medical center program, build residences for its students, and provide it with adequate endowment.

On completion of the medical center's Palo Alto–Stanford hospitals, combined for economics in construction and joint operation, the city hospital will occupy one 226-bed wing of the building, while the other wing will comprise the Stanford teaching hospital. Additional teaching facilities will be afforded by the 1,000-bed Veterans Administration Hospital to be built on Stanford land. Scheduled for completion by 1959, the VA Hospital was planned at Stanford because of its future proximity to the medical center. A group of local physicians, dentists, and businessmen also have leased 10 acres of nearby Stanford land for construction of a 3 million dollar medical-dental office building, to be ready for occupancy by December, 1957.

CONNECTICUT

Dr. Alice Hamilton Honored.—Dr. Alice Hamilton, aged 87, of Hadlyme, has been named "Medical Woman of the Year" by the Boston chapter, American Medical Women's Association. Dr. Hamilton, in 1910, directed the first comprehensive survey of occupational diseases (in Illinois) and in the following years was a leader in bringing the facts of industrial disease and the need for legislation to protect workers before both state and national governments. She served from 1911 to 1920 as a special investigator of poisonous diseases for the U. S. Department of Labor. Dr. Hamilton served as professor of pathology at Northwestern University Medical School in Chicago, as assistant professor of industrial hygiene at the Harvard Medical School, and as a lecturer at Tufts College Medical School, Boston. She is the author of books and scientific papers, including an autobiography, "Exploring the Dangerous Trades" (1943), and a text, "Industrial Toxicology," now in its second edition.

GEORGIA

Appoint Professor of Psychiatry.—Dr. Erasmus J. McCranie, who has served at Southwestern Medical School of the University of Texas, Dallas, as acting chairman of the department of psychiatry since 1953, has been named a professor in the department of psychiatry at the Medical College of Georgia, Augusta. While in Dallas, Dr. McCranie was also consultant to the Child Guidance Clinic and to the Veterans Administration Hospital, as well as attending psychiatrist at Parkland Hospital.

University News.—The Medical College of Georgia, Augusta, announces receipt of research grants from the U. S. Public Health Service, National Institutes of Health, Bethesda, Md., for the following projects:

Walter G. Rice, associate professor of pathology, (1) Origin, Fate and Nature of Myeloma Proteins; (2) Immunologic Specificity of Human Neoplasms.

Edwin C. Jungck, assistant clinical professor of endocrinology, Effect of "Less-Than-Suppressive" Doses of Testosterone on Testes of Infertile Men.

Chester H. Heuser, Ph.D., professor of microscopic anatomy, Morphological Survey of Early Human Embryos.

John M. Caldwell, professor of psychiatry, Improvement of the Undergraduate Teaching Program in Psychiatry, Including Personnel, Equipment, and Supplies.

Sam A. Singal, Ph.D., professor of biochemistry, Study on the Interrelationship of Phospholipid and Nucleic Acids in Metabolism.

Harland D. Wycoff, Ph.D., assistant professor of oncology and biochemistry, Cholesterol Ester Chemistry and Animal Metabolism.

ILLINOIS

Chicago

Meeting on Medical History.—The Society of Medical History of Chicago will hold an open meeting Dec. 19, at 8 p. m., at the Institute of Medicine (fourth floor, 86 E. Randolph St.). All are welcome. Dr. Aldo A. Luisada, associate professor of medicine, the Chicago Medical School, will discuss, "The Heart in History." Dr. George Halperin, Chicago, will have as his subject, "Theodore Billroth."

Appoint Assistant Dean.—Dr. John A. D. Cooper, associate professor of biochemistry, has been appointed assistant dean of Northwestern University Medical School, with which he has been affiliated since 1943. Dr. Cooper has conducted extensive research in physical biochemistry as applied to medical problems and has directed the medical school radioisotope unit since

---

Physicians are invited to send to this department items of news of general interest, for example, those relating to society activities, new hospitals, education, and public health. Programs should be received at least three weeks before the date of meeting.

1948. Dr. Cooper recently directed a course on radioisotope techniques in biology and medicine in Brazil and made a lecture tour of South American universities and scientific societies.

Personal.—Dr. Ralph H. Kuhns, formerly affiliated with the Veterans Administration District Office, Fort Snelling, Minn., has been appointed foreign language expert and psychiatrist for the Veterans Administration regional office in Chicago.——Dr. Jack Metcoff, Evanston, has been named chairman, department of pediatrics and director of pediatric research at Michael Reese Hospital Medical Center. Dr. Metcoff previously served in Boston as chief of the metabolic division of Children's Hospital and as assistant professor of pediatrics and consultant at Harvard Medical School.

MASSACHUSETTS

Personal.—Dr. Charles F. Wilinsky, Brookline, former executive director of the Beth Israel Hospital, Boston, received the 1956 Distinguished Service award of the American Hospital Association at its annual convention in Chicago. The award commends him for his early recognition of the need for coordinated activities between hospitals and health departments and his continued devotion to strengthening this relationship.

Harvard Laboratory Moved to Sweden.—The staff of an entire laboratory of Harvard Medical School and Boston Lying-In Hospital was transplanted to the Karolinska Institute Hospital, Stockholm, Sweden, for a four-month period starting Nov. 1. Under the direction of Claude A. Villee Jr., Ph.D., current studies on changes taking place in embryonic tissue will be expanded in association with the institute staff. Funds for the transportation of laboratory personnel and equipment were made available through the Association for the Aid of Crippled Children.

MINNESOTA

First O'Leary Memorial Lecture.—Dr. Henry E. Michelson, professor of medicine (dermatology) in the University of Minnesota Medical School, Minneapolis, delivered the first annual Paul A. O'Leary Memorial Lecture, "A Consideration of Some Diseases of the Subcutaneous Fat," in Mann Hall, Mayo Clinic, Sept. 8. Dr. O'Leary died on July 20, 1955.

University News.—The University of Minnesota announces the appointment of the following physician members of the Mayo Foundation faculty to full professorships in the graduate school of the university, of which the foundation is a part: Drs. Benjamin M. Black, surgery; Edward N. Cook, urology; Ward S. Fowler, physiology; Haddow M. Keith, pediatrics; and Eric E. Wollaeger, medicine. Appointed to associate professorships are Drs. Albert Faulconer, anesthesiology; George A. Hallenbeck, surgery; Paul R. Lipscomb, orthopedic surgery; Gordon M. Martin, physical medicine and rehabilitation; Donald R. Nichols and Lucian A. Smith, medicine; Charles A. Owen Jr., clinical pathology; and David G. Pugh, radiology. Promoted to assistant professorships are Drs. Donald S. Childs Jr., radiology; Edward C. Clark, Donald W. Mulder, and David de R. Daly, neurology; Henry W. Dodge Jr., neurosurgery; Franklin H. Ellis Jr., surgery; Donald J. Erickson, physical medicine; and Maurice H. Stauffer and William E. Wellman Jr., medicine.

MISSOURI

First Annual Westlake Lecture.—Guest speaker for the first annual Samuel B. Westlake Lecture at the Jewish Hospital medical center, St. Louis, was Dr. Victor Goodhill, clinical professor of surgery (otology) at the University of Southern California School of Medicine, Los Angeles. Dr. Goodhill's lecture on recent advances in the treatment of deafness was delivered Nov. 30. The Samuel B. Westlake Lectures were initiated in memory of Dr. Samuel B. Westlake, for many years an outstanding teacher and director of the department of otolaryngology at Jewish Hospital. They are being made possible by a fund established by Dr. Westlake's patients and friends, to assist in the development of teaching and research facilities at Jewish Hospital for the study of diseases of the ear, nose, and throat.

Personal.—An award for outstanding work in gerontology was presented recently to Dr. Edmund V. Cowdry of Washington University School of Medicine, St. Louis, at a meeting of the Gerontological Research Foundation in St. Louis.——Dr. John P. Wyatt, professor of pathology, St. Louis University School of Medicine, recently spent two months at Scotland Yard, London, as a guest investigator with the coroner system. Dr. Wyatt, who is chief coroner's pathologist for St. Louis County, conducts a training program in the department of pathology at the school of medicine in which graduate students receive instructions in medicolegal pathological investigations.——Dr. Sidney Goldring, Clayton, instructor in neurosurgery, Washington University School of Medicine, St. Louis, has been appointed director of the newly created department of neurosurgery at the Jewish Hospital of St. Louis.

NEW YORK

Dr. Gardner Goes to Yale.—Dr. Lytt I. Gardner, professor of pediatrics, State University of New York College of Medicine in Syracuse, has been appointed professor of pediatrics at the Yale University School of Medicine, New Haven, Conn. Dr. Gardner formerly was affiliated with the Massachusetts General Hospital, Boston; the University of North Carolina School of Medicine, Chapel Hill; and Johns Hopkins University School of Medicine, Baltimore.

Psychiatric Training Program.—The Albany Medical College of Union University, having received grants totaling $22,098 from the U. S. Public Health Service for postgraduate teaching and training of psychiatrists, plans to increase the number of its resident psychiatric trainees from five to eight. A $10,000 increase in the yearly contribution of the Public Health Service to the support of the medical college's undergraduate teaching program in psychiatry will enable the psychiatric department to have one additional instructor and will also benefit residents in psychiatry at the Albany Veterans Administration Hospital, since their third year of training is spent at Albany Medical College.

New York City

Personal.—King Gustaf of Sweden, through the Consul General Erik Kronvall, recently decorated Dr. Harry C. W. S. DeBrun as Knight of Nordstjernan (North Polar Star).

Tumor Clinic Conference.—Dr. Oscar Auerbach, chief, laboratory service, Veterans Administration Hospital, East Orange, N. J., will present "Changes in the Bronchial Epithelium in Its Relationship to Smoking and Cancer of the Lung" at the Harlem Hospital, Dec. 19, 10:45 a. m.

Lecture by Dr. Pasteur Vallery-Radot.—Dr. Pasteur Vallery-Radot, professor of clinical medicine, Faculty of Medicine, University of Paris, France, will deliver the Dr. I. C. Rubin Lecture, "Allergic Manifestations of Interest to the Gynecologist," at 8:30 p. m., Dec. 19, at the Mount Sinai Hospital.

Dr. Hunt Goes to Utah.—Dr. Carlton C. Hunt Jr., professor of physiology, Einstein University, has been appointed head, department of physiology, at the University of Utah College of Medicine, Salt Lake City. He succeeds Horace W. Davenport, Ph.D., who has assumed similar duties at the University of Michigan in Ann Arbor.

Director of Physiology-Pharmacology Department.—Dr. David Lehr, director, department of pharmacology, has been appointed director of the newly combined department of physiology and pharmacology at New York Medical College, Flower-Fifth Avenue Hospitals. Before coming to the college in 1941, Dr. Lehr was on the faculty at the University of Vienna Medical School in Austria, and at the Royal University of Lund in Sweden. Dr. Lehr recently presented a paper at the International Physiological Congress in Brussels on his research with experimental arteriosclerosis. He is chairman of the research committee of the New York Medical College–Metropolitan Medical Center; associate attending physician at Flower–Fifth Avenue Hospitals; and visiting physician at Metropolitan and Bird S. Coler hospitals.

NORTH CAROLINA

Psychiatric Center.—The University of North Carolina School of Medicine, Chapel Hill, announces that an estimated $300,000 building program for the Psychiatric Center of North Carolina Memorial Hospital is scheduled to begin late this year. According to Dr. Robert R. Cadmus, director of the hospital, 50% of the funds required for the project will be supplied by the federal government through the North Carolina Medical Care Commission and the remainder by the state. Plans for the center include laboratories, offices, treatment rooms for the outpatient department, and an auditorium.

University News.—Dr. Walter R. Benson, formerly assistant professor of pathology, University of Louisville (Ky.) School of Medicine, has been appointed to the same post at the University of North Carolina School of Medicine, Chapel Hill.——Dr. Sydenham B. Alexander, clinical assistant professor of medicine, University of North Carolina School of Medicine, Chapel Hill, has been named assistant administrator of the division of health affairs of the University of North Carolina. During World War II, Dr. Alexander was on destroyer duty in the Pacific and during the Korean emergency was chief of diagnostic services of the U. S. Naval Hospital in Portsmouth, Va.

OHIO

Fellowship in Aviation Medicine.—The Air Line Pilots Association, with headquarters in Chicago, has established a $7,200 fellowship in aviation medicine at Ohio State University, Columbus, said to be the first civilian institution to offer graduate training in this specialty. The grant will provide for two years of graduate study.

PENNSYLVANIA

Memorial to Dr. Flick.—Leadership by the late Dr. Lawrence F. Flick in the fight against tuberculosis was honored at a "Dr. Flick Day" program at Carrolltown, Aug. 11, one day after the 100th anniversary of his birth there. A memorial was unveiled, showing a likeness of the medical pioneer with a list of his accomplishments. The bas-relief is flanked by the double-barred cross shown on the Christmas seal. The principal speakers were Dr. Otis L. Anderson, assistant surgeon general, Public Health Service; Dr. Berwyn F. Mattison, Harrisburg, Pennsylvania secretary of health; and Dr. Julius L. Wilson, director, Henry Phipps Institute, Philadelphia. Dr. Flick founded the Pennsylvania Society for the Prevention of Tuberculosis, now the Pennsylvania Tuberculosis and Health Society; was prominent in establishing the Rush Hospital for Consumption and Allied Diseases in Philadelphia; organized the Free Hospital for Poor Consumptives; and helped to establish the Henry Phipps Institute and the National Association for the Study and Prevention of Tuberculosis, now the National Tuberculosis Association. A message from President Eisenhower, accepted by Dr. Lawrence F. X. Flick III, grandson of the late Dr. Flick, read in part: "Largely through the pioneering efforts and dynamic leadership of Dr. Flick, the national movement to combat tuberculosis was initiated. He fought to arouse public interest and organize a crusade against a disease that for centuries has been a plague of mankind."

Philadelphia

Hospital News.—The city-owned Philadelphia General Hospital is featured in a 24-page article in the July issue of *Resident Physician* magazine. The article is the ninth in a series on major medical centers of the United States.

Appointed Professor of Ophthalmology.—Dr. John S. McGavic, who recently resigned as pathologist and chief of laboratories at the Wills Eye Hospital, has been appointed professor of ophthalmology, Temple University Medical Center, where he served as professor of clinical ophthalmology from 1947 to 1950. He was formerly professor of clinical ophthalmology at the University of Pennsylvania Graduate School of Medicine, chief, ophthalmology service, Pennsylvania Hospital, and assistant ophthalmologist at the Memorial Hospital for Cancer and Allied Diseases in New York City. He is in charge of the ophthalmology service at Bryn Mawr Hospital.

Pittsburgh

Mellon Institute Appoints Research Director.—Paul J. Flory, Ph.D., professor of chemistry and acting chairman, department of chemistry, Cornell University, Ithaca, N. Y., was recently chosen by the Mellon Institute of Industrial Research as executive director of research.

UTAH

University News.—The University of Utah College of Medicine, Salt Lake City, announces that Dr. Maxwell M. Wintrobe, head, department of internal medicine, was recently given a three-months' leave of absence in the Far East on a Fulbright Lectureship with headquarters in India.——Norman Weissman, Ph.D., formerly of the State University of New York College of Medicine, recently became associate professor of pathology, and Dr. Julien L. VanLancker, from Louvain, Belgium, was named assistant professor of pathology.——Dr. Erik L. Noach, associate professor of pharmacology, State University of Leiden, Holland, is spending a research fellowship year in the department of pharmacology.——Dr. Yoshitoshi Kasé, assistant professor, department of chemicopharmacology, faculty of pharmacy, University of Kumamoto, Japan, is spending a research fellowship year in the department of pharmacology, working on central respiratory mechanisms.

GENERAL

Award to Dr. Elvehjem.—Conrad A. Elvehjem, Ph.D., dean, graduate school, University of Wisconsin, Madison, was recently named the 1956 recipient of the Charles F. Spencer award of the Kansas City section, American Chemical Society. The award includes a medallion and a $500 honorarium. Dr. Elvehjem, who with his co-workers showed that nicotinic acid was the specific antipellagra vitamin, is a member of the A. M. A. Council on Foods and Nutrition.

Gordon Research Anniversary Dinner.—A dinner to mark the silver anniversary of the founding of the Gordon Research Conferences of the American Association for the Advancement of Science will be held at the Hotel Commodore, New York City, Dec. 27, during the annual meeting of the association. The principal speaker will be Nobel prize winner Glenn T. Seaborg, Ph.D., whose topic will be "The Future Through Science." Reservations, at $10 per person, may be made by writing to W. George Parks, Ph.D., Director, Gordon Research Conferences, University of Rhode Island, Kingston.

Awards for Handicapped Service.—According to the International Society for the Welfare of Cripples and the Albert and Mary Lasker Foundation, three Albert Lasker awards for outstanding achievement in the development of services for the physically disabled will be presented at the seventh World Congress of the society in London, July 24, 1957. The awards, made by the foundation through the society every third year for internationally significant individual and group accomplishments, consist of $1,000 each and a silver statuette of the Winged Victory of Samothrace. Dr. Henry H. Kessler, West Orange, N. J., will be chairman of the Lasker awards committee.

Meeting on Premedical Education.—A symposium, "Problems in Premedical Education," will be presented in the auditorium of Cornell University Medical College, New York, Dec. 29, by Alpha Epsilon Delta fraternity, with the co-sponsorship of the American Association for the Advancement of Science section C-chemistry, F-zoological sciences, N-medical sciences, and Beta Beta Beta Biological Society, and in conjunction with the annual meeting of the American Association for the Advancement of Science. All persons interested in premedical education are invited to attend. Physicians participating in the program will include William N. Hubbard Jr., Lawrence W. Hanlon, E. Hugh Luckey, New York City; and George E. Miller Jr., Buffalo.

Discontinue Shipping Medical Books to Korea.—The American-Korean Foundation and the U. S. Army Medical Service have announced the discontinuation of their joint project of shipping medical books contributed by individual physicians, medical schools, hospitals, and state and local medical societies to Korea

Books should not be sent to the Sharpe General Depot as in the past, because facilities no longer exist for packing and transshipping contributions to Korea. In making the announcement, Dr. Howard A. Rusk, chairman, American-Korean Foundation said, "The response of physicians and medical groups throughout the country for our appeal for books for Korean medical schools has been so generous that further contributions are not needed." As a result of this program, Dr. Rusk stated, over 76 tons (valued at $75,000) of medical texts, references, and periodicals have been shipped to Korea for distribution to Korean medical schools.

International Medical Film Program.—The international medical film program, a new feature for the A. M. A. Annual Meeting in New York City next June, is creating interest abroad. The many applications now coming in indicate an extensive program of medical films made in other countries. The aim of the program is to bring before the doctors who attend the New York meeting outstanding motion pictures produced abroad dealing with many aspects of medical science. This feature is in support of the people-to-people program that President Eisenhower launched this summer and in which the medicine and health professions are cooperating under the chairmanship of Dr. Louis H. Bauer, secretary general of the World Medical Association, New York. Although the film program is not competitive, a certificate of participation will be awarded to each film of distinction selected for showing. In connection with this program, which will be held at the Barbizon Plaza Hotel in New York next June 3-7, a discussion is planned on the problems of a freer international medical film exchange. Representatives of all countries interested in dissemination of medical knowledge by the film medium are invited. Special social events will also provide an opportunity for the participants to meet informally and discuss problems of mutual interest. The film program will be scheduled to permit participants to visit scientific exhibits and other programs, including color television, as guests of the A. M. A. Applications and information may be obtained from the American Medical Association, Motion Pictures and Medical Television, 535 N. Dearborn St., Chicago 10.

Lalor Faculty Awards.—The Lalor Foundation announces the availability of 40 awards to college and university staff and faculty members for research in the biological sciences for the summer of 1957. The awards for advanced study and research employing chemistry or physics to attack problems in any field of biology may be carried on at any institution of the award-holder's choice. The upper age limit for appointment is 40 years. The awards will usually not exceed $900 for a single man or woman, $1,100 for a married person working at his home institution, and $1,250 for a married person whose principal program is at another institution. Transportation and other expenses are for the account of the award holder. Inquiries should be addressed to the Director of the Lalor Foundation, 4400 Lancaster Pike, Wilmington 5, Del. The final date for the receipt of completed applications is Jan. 14, 1957.

FOREIGN

Residency Posts for Doctors from India.—The Indian Medical Association requests offers from recognized U. S. hospitals for residency and internship posts in all specialties for doctors from India, men and women with a good command of spoken and written English, specially selected for graduate training in U. S. hospitals for the session commencing July, 1957. The hospitals must be approved by the U. S. State Department for the exchange-visitor program. Interested hospitals are requested to communicate direct by air mail to the Honorary Secretary, Indian Medical Association, "Hanging Bridge," Daryaganj, Delhi, 7, India, giving offers of posts and the terms of appointment, including maintenance, stipend, and the allotted number for the exchange-visitor program.

Congress on Occupational Health.—The 12th International Congress on Occupational Health will convene July 1-6, 1957, in Helsinki, Finland, to discuss industrial noise, evaluation of invalidity, industrial hygiene norms, and cardiacs and work. Persons who wish to present original scientific papers on these or on any other topics are invited to notify the organizing committee before March 1, 1957, giving the title of the paper and a summary of not more than 200 words in English and French. The Nicolò Castellino prize, 3 million lire (approximately $4,800), will be awarded for the first time at the congress for the most outstanding investigation in the field of occupational health by a research worker, who must be under the age of 35 years and who is not the holder of a university chair. Details can be obtained from Directors of Nicolò Castellino Prize. The University. Naples, Italy. The congress will also have a competition for films concerned with occupational medicine and hygiene (accident prevention films do not qualify for the competition). There will be two classes, one for research and documentary films and the other for popular films for lay audiences. Films may be 16 or 35 mm., in color or black and white, with or without sound track, and must not exceed 20 minutes. Films must be received no later than May 15, 1957, by the Organizing Committee of the Congress at Työterveyslaitos, Haartmaninkatu 1, Helsinki-Töölö. Entries must state by whom the film has been planned, produced, and financed. Information relating to the congress may be had on application to the Organizing Committee, Chairman Dr. Leo Noro and Secretary General Dr. Pentti Sumari.

EXAMINATIONS AND LICENSURE

American Board of Anesthesiology: *Part I.* Various locations, July 19. Final date for filing application is Jan. 19. *Oral.* Asheville, No. Car., Mar. 24-29. Sec., Dr. Curtiss B. Hickcox, 80 Seymour St., Hartford 15, Conn.

American Board of Dermatology: *Written.* Several cities, June 27. *Oral.* Baltimore, Oct. 11-13. Sec., Dr. Beatrice Maher Kesten, One Haven Ave., New York 32.

American Board of Internal Medicine: *Written.* Oct. 21. *Oral.* New Orleans, Feb. 4-8; Boston, April 3-6. Final date for filing application is Jan. 2. Chicago, May 27-29; San Francisco or Los Angeles, September. Final date for filing application is Feb. 1. *Subspecialties. Gastroenterology.* Philadelphia, April 5-6. Final date for filing application is March 1. Exec. Sec., Dr. W. A. Werrell, 1 West Main St., Madison 3, Wis.

American Board of Neurological Surgery: Examination given twice annually, in the spring and fall. In order to be eligible a candidate must have his application filed at least six months before the examination time. Sec., Dr. Leonard T. Furlow, Washington University School of Medicine, St. Louis 10.

American Board of Obstetrics and Gynecology: *Part I.* Various cities of the United States, Canada, and military centers outside the Continental United States, Feb. 1. Candidates must submit case reports to the office of the Secretary within thirty days of being notified of their eligibility to Part I. The cases must be prepared in the manner described in the Bulletin of the board with a duplicate index list. *Part II.* Chicago, May 16-25. Request for reexamination in Part II must be received prior to Feb. 1. Sec., Dr. Robert L. Faulkner, 2105 Adelbert Road, Cleveland 6, Ohio.

American Board of Ophthalmology: *Written.* Jan. 21. Final date for filing application was July 1. *Oral.* New York, May 23-27; Chicago, Oct. 7-11. Sec., Dr. Merrill J. King, Box 236, Cape Cottage Branch, Portland 9, Maine.

American Board of Orthopaedic Surgery: *Oral. Part II.* Chicago, January 1957. Final date for filing application was Aug. 15. Sec., Dr. Sam W. Banks, 116 South Michigan Ave., Chicago 3.

American Board of Otolaryngology: Chicago, Oct. 7-11. Final date for filing application is April. Sec., Dr. Dean M. Lierle, University Hospitals, Iowa City.

American Board of Pathology: *Oral and Written. Pathologic Anatomy and Clinical Pathology.* Washington, April 4-6. Final date for filing application is March 1. Sec., Dr. Edward B. Smith, 1040 West Michigan St., Indianapolis 5.

American Board of Physical Medicine and Rehabilitation: *Parts I and II.* New York City, June 8-9. Final date for filing application is March 1. Sec., Dr. Earl C. Elkins, 200 First St., S.W., Rochester, Minn.

American Board of Plastic Surgery: *Entire Examination.* Philadelphia, May 4-6. Final date for filing case reports is Jan. 1. Corres. Sec., Mrs. Estelle E. Hillerich, 4647 Pershing Ave., St. Louis 8.

American Board of Preventive Medicine: *Oral and Written. Public Health.* Schools of Public Health, April 11-13. *Aviation Medicine.* Denver, May 9-11. *Occupational Medicine.* St. Louis, April 26-28. Sec., Dr. Thomas F. Whayne, 615 North Wolfe St., Baltimore.

American Board of Proctology: *Oral and Written. Parts I and II.* September. Sec., Dr. Stuart T. Ross, 520 Franklin Ave., Garden City, N. Y.

American Board of Psychiatry and Neurology: *Oral.* New Orleans, Mar. 18-19. Final date for filing application was Sept. 10. Sec., Dr. David A. Boyd, Jr., 102-110 Second Ave., S.W., Rochester, Minn.

American Board of Radiology: Tampa, April 1-6. Final date for filing application is Jan. 1. Washington, Sept. 23-28. Final date for filing application is June 1. Sec., Dr. B. R. Kirklin, Kahler Hotel Bldg., Rochester, Minn.

American Board of Surgery: *Part II.* Los Angeles, Jan. 14-15; San Francisco, Jan. 17-18; Houston, Feb. 18-19; Nashville, Mar. 11-12; Boston, April 8-9, and New York, June 10-11.

American Board of Urology: February 1957. Sec., Dr. William Niles Wishard, 1711 N. Capital Ave., Indianapolis 7.

Board of Thoracic Surgery: *Written.* Various centers throughout the country, February 1957, and the closing date for registration is Dec. 1, 1956. Sec., Dr. William M. Tuttle, 1151 Taylor Ave., Detroit 2.

GOVERNMENT SERVICES

ATOMIC ENERGY COMMISSION

Dr. Bruner Appointed to AEC.—Dr. Harry D. Bruner has been appointed chief of the medical branch of the division of biology and medicine, Atomic Energy Commission, succeeding Dr. Roy E. Albert, who has accepted a research and academic appointment at George Washington University, Washington, D.C.

Dr. Bruner received an M.D. from the University of Louisville, Ky., and a Ph.D. in physiology from the University of Chicago. He was chairman of the pharmacology department at the University of North Carolina from 1947 until 1949, when he became chief scientist, medical division, Oak Ridge Institute of Nuclear Studies in Tennessee, serving until 1952, when he was appointed chairman of the department of physiology at Emory University, Ga.

As chief of the medical branch, Dr. Bruner will be responsible for administering the commission's medical program, including research on the mechanism, diagnosis, and treatment of radiation injury and the application of radioisotopes to the diagnosis and treatment of disease; research on toxicity of chemical compounds used in the atomic energy program; and the training of industrial physicians.

ARMY

Proposed Ionizing Radiation Center.—The proposed U. S. Army Ionizing Radiation Center will be located at the Sharpe General Depot, Stockton, Calif. The experimental center will include a nuclear reactor, built by the Atomic Energy Commission, which, together with related equipment, will cost about $3 million dollars. The reactor will be a source of intense gamma radiation.

The center will investigate the use of ionizing radiation in the preservation of foods and conduct other projects of interest to the Department of Defense. The processing area will be designed so that a large variety of products may be handled and major modifications in processing lines may be effected. The Quartermaster Research and Development Command at Natick, Mass., will direct the operations of the center.

The Quartermaster Food and Container Institute, Chicago, is conducting the over-all Quartermaster Corps research and development program in the field of radiation preservation of food. This program includes contracts with 16 universities and with research institutes and industrial concerns throughout the country. The food processed through the Army Ionization Radiation Center will be used in part for support of these contracts. It is expected that work will commence during this fiscal year and that the center will be in operation late in 1958.

NAVY

Reserve Officers Transfer to Regular Navy.—The following naval reserve medical officers have recently been commissioned in the Medical Corps of the regular Navy: Commander D. L. Custis, lieutenants J. D. Manhart, J. L. Glass, J. L. Reeder, T. R. Kleh, F. R. Walton, R. D. Cordier, C. E. Carlton Jr., F. M. Wolfe, R. E. Donahue, V. H. Fitchett, J. R. Williams, M. F. Sokoloff, C J. Philbrick, E. H. Lanphier, C. J. McGrew Jr., J. D. Gross, J. W. Bickerstaff Jr., E B. McMahon, E. P. Ellis Jr., T. S. Dunn Jr., Robert A. Smith, Samuel O. Cornwell, John H. Mazur, John F. Heath, H. R. Schumacher, David E. Cowan, and Erwin L. Burker, and Lieut. Commander R. D. Workman.

Dr. Selye's Address at Navy Hospital.—Dr. Hans Selye, director, Institute of Experimental Medicine and Surgery at Canada's Université de Montreal, addressed the staff of the U. S. Naval Hospital, Corona, Calif., Nov. 13. Also attending the lecture were students and faculty members of the University of California interested in Dr. Selye's work on stress.

Personal.—Dr. Howard T. Karsner, medical research advisor to the surgeon general of the Navy, has been elected a member of the New York Academy of Sciences.

Navy Crew Commended.—Hospital corpsmen and nonmedical personnel of the USS *Salem* were commended by the commanding officer for excellent performance of duty in handling the injured personnel of the USS *John R. Pierce* when on Oct. 1, 1956, a 5-in. gun-mount exploded aboard the destroyer, injuring 13 of its crew members. The *Pierce* transferred the injured men via high line to the *Salem*, whose medical personnel and other crew members cared for them and further transferred them to a nearby airfield for evacuation to a naval hospital. The acting surgeon general, Rear Adm. Bruce E. Bradley, added his congratulations to the men who performed their duty so outstandingly.

Captain Poos Awarded Gorgas Medal.—For contributions in preventive medicine while officer-in-charge, U. S. Navy preventive medicine unit no. 6, Hawaii, Capt. Robert S. Poos, Medical Corps, retired, received the Gorgas medal at the annual meeting of the Association of Military Surgeons in Washington, D. C., in November. Dr. Poos was selected for the award for his work relative to poliomyelitis among naval personnel and their dependents in Hawaii and to the use of Salk poliomyelitis vaccine under epidemic conditions. Dr. Poos, a native of Missouri, and Mrs. Poos reside at Claremont, Calif.

Guam Hospital Staff Commended.—At the recent third special session of the Guam Legislature, the medical department staff of the U. S. Naval Hospital on Guam were commended for their extraordinary services in furnishing supplementary medical care and consultations to the people of Guam at their Memorial Hospital. Capt. Frank P. Kreuz, M. C., U. S. Navy, is commanding officer of the Naval Hospital at Guam.

Medal Awarded to Navy Doctors.—The Association of Military Surgeons at their annual convention in November in Washington, D. C., awarded the Founders medal for 1956 to Capt. Eugene V. Jobe, M. C., U. S Navy, and Capt. Walton L. Jones, M. C, U. S. Navy. The Founder's medal is given for outstanding contribution to military medicine and meritorious service to the association. Captains Jobe and Jones are on duty in Washington, D. C., at the Navy's bureau of medicine and surgery.

AIR FORCE

New Air Force Medical Officers.—The U. S. Air Force Medical Service announced that the following 24 physicians were tendered regular appointments in the Air Force about Oct. 1, 1956. Albert S. Anderson, Dewey J. Bailey Jr., Laurence T. Beahan, Edwin A. Bowman, Kenneth P. Carlson, Gerald Davis, Robert M. Dean, William A. Dunnagan, James A. Gorman Jr., Jere D. Guin, John B. Longenhagen, Strother B. Marshall, James W. Mason, Donald E. McNealy, Francis C. Null Jr., John R. Pfrommer, Eldred T. Richey Jr., William W. Rueve, James J. Schubert, Kuno C. Schwarz, W. T. Snodgrass, Dennis J. Sullivan, Charles O. Titus, and Hiroshi Yamauchi.

Personal.—Brig. Gen. Victor A. Byrnes, director, professional services, office of the surgeon general, U. S. Air Force, delivered the Mc Reynolds Memorial Lecture on "Eye Injuries Produced by Atomic Explosion" at the University of Texas, Oct. 31.

VETERANS ADMINISTRATION

New Clinical Investigator Program.—The Veterans Administration, Washington, D. C., has made the following announcement

The needs of the Veterans Administration medical program and the potential of its research and education activities in contributing to the nation's health are such that the VA plans to train selected physicians and dentists whose primary responsibility will be medical research. The candidates must be interested in problems of importance in the care of veteran patients in fields basic to neurology and psychiatry, cardiovascular disease, cancer, degenerative diseases, and problems involving the aging process. Maximum freedom of choice of subject will be allowed within these broad fields. Any physician or dentist is eligible who has completed at least the formal residency training period required prior to American specialty board certification and who because of special interest and aptitude wishes to do full-time research for a period of possibly up to three years.

The clinical investigator will spend at least three-fourths of his time in research. The balance of his time may be spent in teaching and patient care or in whatever professional activity he and his sponsors agree is advantageous for his development. He will be appointed as a full-time member of the Veterans Administration hospital staff, and his official title will be Veterans Administration clinical investigator. He will be entitled to the privileges and benefits of other full-time physicians and dentists, such as insurance and retirement eligibility and annual and sick leave. All clinical investigators will have research as their primary responsibility; they will, in addition, hold suitable clinical appointments on the hospital staff that will enable them to enjoy the privileges of a responsible relation to the patient care program. The clinical investigator will be appointed at intermediate grade. The beginning salary is $8,990 per year. Additional credit will be given for American specialty board certification in accordance with existing regulations.

Candidates are nominated to the VA hospital manager through the VA hospital research committee for approval by the deans committee. From the group of nominees the clinical investigators will be selected by the central advisory committee composed of outstanding educators and investigators. The candidate should submit a *curriculum vitae*, including transcripts of his scholastic record and other information that might help the committee in its evaluation. He should prepare a detailed description of his proposed research program and make a brief statement of his future plans and ambitions. The candidate should select a preceptor who will follow his career throughout the period of appointment. The preceptor may be any person approved by the deans committee, within or without the Veterans Administration. The sponsoring hospital will describe the research and other facilities available for use by the investigator. Additional information and assistance in completing the application should be secured from the deans committee or hospital manager. In making the final selection the central advisory committee will consider not only the qualifications of the candidate but the ability of the hospital to provide an atmosphere conducive to his development.

Selection will be made semiannually for January and July appointment. Applications may be obtained from the manager of the VA hospital of choice. The completed forms are submitted by the deans committee to the Office of the Assistant Chief Medical Director for Research and Education, Veterans Administration, Washington 25, D. C. The candidates will be notified of their selection by the chief medical director through the hospital manager.

Awards to Employees at Fort Lyon Psychiatric Hospital.—The employees of the VA hospital at Fort Lyon, Colo., received an award of $4,360 presented by Dr. William S. Middleton, VA chief medical director, in a ceremony at the hospital on Nov. 12. Each of the 436 employees of the hospital who were on duty six months or more as of May 2 received $10 and a certificate of commendation for superior performance and teamwork. Dr. Middleton said that the Fort Lyon Hospital had received the Achievement Award of the Year from the American Psychiatric Association for showing the most improvement in patient care of any hospital in the United States during 1955. The VA's award demonstrates, it was said, that modern psychiatric care can be made available at an isolated station operating with a limited but devoted medical staff. Dr. Howard P. Morgan is the hospital manager.

Fort Lyon, a 781-bed hospital specializing in the care of mentally ill veterans, is located on the site of an old frontier post, later a military fort. The Navy established a tuberculosis hospital there in 1906 and the VA took it over in 1922.

Hospital News.—Dr. Alvin Turken, Tarrytown, N. Y., addressed the staff of the Veterans Administration Hospital at Northport, L. I., Oct. 30, on "Application of Orthopedic Measures in Neuro-Psychiatric Problems."

PUBLIC HEALTH SERVICE

New Program to Increase Research Manpower.—The Public Health Service announced Nov. 20 five-year research fellowship awards to 44 scientists in 29 universities and medical schools in 20 states, the District of Columbia, and Canada. The awards are the first in a new federal program designed to increase manpower for research in the basic medical sciences. Recipients are scientists who have completed their doctor's degrees in biochemistry, pharmacology, physiology, microbiology, pathology, and the psychological sciences. Each fellow will receive a salary not to exceed $10,000 yearly, plus up to $2,000 to defray part of the expenses of his research. The salary level is set by the institution to approximate the salaries of scientists doing similar research and teaching as members of the regular faculty. These fellowships will permit recipients to continue their research activities. Concurrently, the sponsoring institutions will assign appropriate teaching responsibilities so that fellows may qualify for full-time academic positions at higher levels.

The new program results from over two years of study by the Public Health Service, aided by experts and the advice of medical school deans and heads of university departments concerned with research and teaching in the basic medical sciences. In citing the need for senior fellowships, the surgeon general said a survey revealed that for the current year over 200 authorized and budgeted positions on the faculties of medical and basic science schools are unfilled. Included are 55 professorships, 52 associate professorships, and 79 assistant professorships. He added that about the same number of vacancies existed last year.

The Public Health Service will award between 40 and 50 new fellowships annually until about 250 have been given by the fifth year. Thereafter the program will be maintained at this level until the national deficiencies have been met. The total cost of the first year of the program will be about $500,000.

Aid to Build Sewage Treatment Works.—The Public Health Service is ready to act on applications for federal grants to help build sewage treatment facilities, and criteria for determining the propriety of federal aid have been established.

Congress appropriated 50 million dollars for the new construction-grants program during the current fiscal year. The new act limits individual grants to 250 thousand dollars or 30% of the estimated cost of the project, whichever is less. Among other conditions, to be eligible for a federal grant a project must be part of a comprehensive water pollution control program developed cooperatively by the Public Health Service, other federal agencies, state and interstate agencies, municipalities, and industries. The program list now includes about 10,000 municipalities. In addition, eligible projects must be in conformity with the state water pollution control plan and must have been certified by the state water pollution control agency as entitled to priority over the other eligible projects on the basis of financial as well as water pollution control needs.

Annual Survey of Illness.—Forrest E. Linder, Ph.D., has been named director of a new Public Health Service program to survey the nature and extent of illness and disability in the population each year. The survey, authorized by the past Congress, also will include data on medical services received by the ill and disabled. The last previous federal survey of this type was in 1936. The Public Health Service plans to use scientific door-to-door sampling techniques to obtain accurate information on the amount, distribution, and effects of illness and disability, and the services received because of such conditions.

Dr. Linder, a native of Waltham, Mass., comes to the Public Health Service from the United Nations statistical office. He received his doctor of philosophy degree from the State University of Iowa. Prior to his work with the United Nations, he was deputy chief of the National Office of Vital Statistics of the Public Health Service.

Personal.—Dr. Donald W. Patrick, director, Clinical Center of the National Institutes of Health, at Bethesda, Md., has been appointed medical officer in charge of the Public Health Service Hospital at San Francisco, succeeding Dr. Kenneth R. Nelson, who is being transferred to Washington, D. C., to be associate chief of the Bureau of Medical Services.—Dr. Edgar B. Johnwick has been appointed medical officer in charge of the U. S. Public Health Service Hospital (National Leprosarium), Carville, La., succeeding Dr. Eddie M. Gordon Jr., newly appointed chief quarantine officer at Fort Monroe, Va., in charge of foreign quarantine activities in the Norfolk and Hampton Roads area. The Public Health Service at Carville, La., is the only institution in the continental United States devoted exclusively to the treatment and rehabilitation of persons with leprosy.

DEATHS

Osgood, Robert Bayley ⊕ Boston; born in Salem, Mass., July 6, 1873; Harvard Medical School, Boston, 1899; John B. and Buckminster Brown professor of orthopedic surgery emeritus at his alma mater; specialist certified by the American Board of Orthopaedic Surgery; past-president of the American Orthopaedic Association and the New England Surgical Society, member of the American Academy of Orthopaedic Surgeons, American Academy of Arts and Sciences, International Society of Orthopaedic Surgery, and the Boston Surgical Society; corresponding member of the Belgian Orthopaedic Association and the Australian Orthopaedic Association; honorary member of the British Orthopaedic Association, Italian Orthopaedic Association, and the Scandinavian Orthopaedic Association; fellow of the American College of Surgeons; veteran of World War I; *honorary surgeon and formerly* chief of staff, orthopedic service, Massachusetts General Hospital; consultant at the Children's Hospital, where he was formerly chief of staff, orthopedic service; died Oct. 2, aged 83.

Behan, Richard Joseph ⊕ Pittsburgh; born in Pittsburgh June 1, 1879; Western Pennsylvania Medical College, Pittsburgh, 1902; served on the faculty of his alma mater; past-president of the Allegheny County Medical Society; member of the Pittsburgh Surgical Society; fellow of the International College of Surgeons and the American College of Surgeons, of which he was an ex-governor; served in the Red Cross during the Serbian-Bulgarian War in 1913 and in recognition of his services was decorated by King Peter of Serbia; veteran of World War I; author of several books; from 1915 to 1939 chest surgeon at the Leech Farm Sanatorium; from 1922 to 1938 on the staff of the Pittsburgh City Home and Hospitals in Mayview, Pa.; from 1939 to 1942 medical director of the Allegheny County Institution District Hospital in Woodville; on the staff of St. Joseph's Hospital and Dispensary, where he died Oct. 8, aged 77, of a cerebral accident.

Jones, Isaac Hampshur ⊕ Los Angeles; born Sept. 26, 1881, University of Pennsylvania Department of Medicine, Philadelphia, 1906; member of the Association of Military Surgeons of the United States, American Laryngological, Rhinological and Otological Society and the American Otological Society, past-president of the Pacific Coast Oto-Ophthalmological Society; specialist certified by the American Board of Otolaryngology; fellow of the Aero Medical Association; during World War I served on recruiting duty for the newly-created aviation section of the Signal Corps; served abroad, for which he was made a Chevalier of the French Legion of Honor, formerly on the faculty of the University of Southern California School of Medicine; served on the staffs of the Los Angeles County Hospital and the Hospital of the Good Samaritan; died Sept. 7, aged 74, of carcinoma of the parotid gland with metastases

Miller, Felix Perryman ⊕ El Paso, Texas; born in Coryell Aug. 20, 1874; University of Texas School of Medicine, Galveston, 1899; formerly a pharmacist; specialist certified by the American Board of Surgery; member of the American College of Chest Physicians and the American Association for the Surgery of Trauma; fellow of the International College of Surgeons and the American College of Surgeons, member of the House of Delegates of the American Medical Association in 1930-1931 and from 1935 to 1939, past-president of the Medical Association of Texas and *the El Paso County Medical Society;* served on the county health board, on the staffs of the Southwestern General Hospital, Providence Memorial Hospital, and Hotel Dieu, Sisters' Hospital, consultant, William Beaumont Army and El Paso General hospitals, died Aug. 23, aged 82, of carcinoma of the liver.

Dobbie, Robert Paul ⊕ Buffalo; born in Buffalo in 1895; University of Buffalo School of Medicine, Buffalo, 1917; clinical professor of surgery at his alma mater; member of the American Association for the Surgery of Trauma and the Industrial Medical Association; fellow of the American College of Surgeons; member of the founders' group of the American Board of Surgery; past-president of the Buffalo Academy of Medicine and the Buffalo Surgical Society; for many years senior surgeon for the Republic Steel Corporation and the Donner-Hanna Coke Corporation; on the staff of the Buffalo General Hospital, where he was president of the medical staff and at one time secretary and treasurer; on the staffs of the Children's Hospital and the Edward J. Meyer Memorial Hospital; died in the Buffalo General Hospital Aug. 27, aged 60, of malignant hypertension.

Petty, Wallace Sidney ⊕ Macon, Mo.; born in Millport July 13, 1887; Keokuk Medical College, College of Physicians and Surgeons, Keokuk, Iowa, 1908; *completed a course in public health* at the University of Minnesota, Minneapolis, in 1941; specialist *certified by the American Board of Preventive Medicine,* past-president of the Iowa Public Health Association; in 1942 elected vice-president of the International Society of Medical Health Officers; veteran of World War I; *served as director of the* Woodbury County (Iowa) health unit and the Sioux City (Iowa) Health Department; formerly director of the divisions of local health services and communicable disease control, and state director of health, Nebraska Department of Health; district health officer for the Missouri State Department of Health, died Sept. 9, aged 69, of cerebral hemorrhage.

Wilson, David Alexander ⊕ Greenville, S. C.; born in East Liverpool, Ohio, Feb. 1, 1910; *Ohio State University College of Medicine, Columbus, 1938; specialist certified by the American Board of Surgery; member of the Southeastern Surgical Congress;* fellow of the American College of Surgeons; interned at the Duke Hospital in Durham, N. C., where he served a residency; formerly a resident at the Franklin County Sanatorium in Columbus, Ohio, and the Kent General Hospital in Dover, Del.; served as president of the South Carolina Surgical Society; on the staff of the Greenville General Hospital, member of the board of directors of the Greenville Chamber of Commerce, died Sept. 17, aged 46.

Teveluwe, William Anthony, *Blanco,* Texas; born in Cincinnati July 23, 1877; *Cincinnati College of Medicine and Surgery,* Cincinnati, 1898; *past vice-president of the* Hayes-Blanco Counties *(Ohio) Medical Society;* a draft board physician during World War II, *formerly* practiced in Cincinnati, where he was on the staffs *of the St. Francis* Hospital, Good Samaritan Hospital, *and* St. Mary's Hospital, where he was president of the staff in 1932; served as attending physician at Mount Alverno Home for Boys in Cincinnati, on the staff of the Hospital in the Hills, where he died Sept. 18, aged 79, of cancer of the sigmoid.

Artman, Byron E., Wichita, *Kan.*; Eclectic Medical Institute, Cincinnati, 1888, died Sept. 22, aged 90.

Brown, Elmer Jonathan ⊕ Manchester, N. H., Medical School of Maine, Portland, 1910, member of the American Urological Association; for many years on the staff of the Elliot Hospital died Oct. 6, aged 72, of cerebral hemorrhage.

Bundsen, Charles Albin ⊕ Denver, Gross Medical College, Denver, 1902, veteran of the Spanish-American War, member of the American College of Chest Physicians and the American Trudeau Society, formerly member of the state board of health once decorated by the King of Sweden, for many years on the *staff of the Mercy* Hospital; founder and retired medical director of the Swedish National Sanatorium in Englewood, where he died Sept. 3, aged 83, of arteriosclerosis.

Conliffe, Milton Mitchinson, *Fairmont,* W. Va.; College of Physicians and Surgeons, Boston, 1914, an associate member of the American Medical Association; served on the staff of the Fairmount *General Hospital;* died in a New York hospital Oct 1, aged 71.

Cox, Walter Edward ⊕ Brownsville, Texas; University of Arkansas School of Medicine, Little Rock, Ark., 1912, *served as health* unit director for the state health department; *died Sept. 17,* aged 78, of arteriosclerosis.

⊕ Indicates Member of the American Medical Association.

Dale, Joseph Wilbur ⊕ Chesterton, Ind.; Chicago College of Medicine and Surgery, Chicago, 1910; past-president of the Porter County Medical Society; served on the staff of the Porter Memorial Hospital in Valparaiso; died in Westville Aug. 18, aged 68.

Dixon, Francis Samuel ⊕ Natchez, Miss.; Tulane University School of Medicine, New Orleans, 1932; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; served as secretary of the Adams County Medical Society; consultant, Natchez Charity Hospital, where he was superintendent; on the staffs of the Natchez General Hospital and the Natchez Sanatorium, where he died Oct. 3, aged 55, of coronary thrombosis.

Fenn, Harry Todd, Mount Dora, Fla.; University of Alabama School of Medicine, Mobile, 1911; member of the Florida Medical Association; died in the Orange Memorial Hospital, Orlando, Oct. 6, aged 69, of cerebral thrombosis.

Fisher, Charles Thompson ⊕ Salisbury, Md.; University of Maryland School of Medicine, Baltimore, 1901; fellow of the American College of Surgeons; past-president of the Wicomico County Medical Society; served on the staff of the Peninsula General Hospital, where he died Sept. 19, aged 77, of heart disease.

Gambacorta, Leopoldo ⊕ Newark, N. J.; Regia Università di Napoli Facoltà di Medicina e Chirurgia, Italy, 1906; on the staff of the Columbus Hospital; died Aug. 23, aged 75, of cerebral hemorrhage.

Garvin, Edward Ralph, Toledo, Ohio; St. Louis University School of Medicine, St. Louis, 1931; veteran of World War II and received a Navy Commendation Ribbon and citation for "meritorious and efficient performance of duty"; on the staffs of the Mercy Hospital and St. Charles Hospital, where he was chief of obstetrics and gynecology and where he died Sept. 19, aged 50, of coronary occlusion with myocardial infarction.

Hackney, Ben Hall, Lucama, N. C.; Medical Department of Tulane University of Louisiana, New Orleans, 1911; died Oct. 2, aged 68, of coronary thrombosis.

Hanks, Ralf ⊕ Fulton, Mo.; St. Louis University School of Medicine, St. Louis, 1926; member of the American Psychiatric Association; past-president of the Missouri Association for Mental Hygiene; interned at St. John's Hospital in St. Louis; formerly resident physician at the Missouri State Hospital No. 4 in Farmington; served as superintendent of state hospitals in St. Joseph, Nevada, and Fulton, where he died Sept. 24, aged 61, of cerebral hemorrhage.

Hannett, James Wallace ⊕ Clyde, N. Y.; Syracuse University College of Medicine, Syracuse, 1908; member and past-president of the New Mexico Medical Society; fellow of the American College of Surgeons; for many years practiced in Albuquerque, N. Mex.; died Sept. 23, aged 74, of carcinoma of the left main bronchus.

Hansen, Roy Theodore ⊕ Hartland, Wis.; Marquette University School of Medicine, Milwaukee, 1918; for many years practiced in Wauwatosa, where for many years he was health officer; served on the staffs of the Johnston Emergency and Mount Sinai hospitals in Milwaukee; died Aug. 21, aged 63, of cardiac decompensation and coronary thrombosis.

Harrell, Forrest Worth ⊕ Jennings, La.; Tulane University School of Medicine, New Orleans, 1922; veteran of World Wars I and II; died Sept. 21, aged 58.

Harris, J. Monroe, Allsboro, Ala. (licensed in Alabama, year unknown); died Aug. 31, aged 88.

Jacobson, Jacob ⊕ Chicago; Loyola University School of Medicine, Chicago, 1919; on the staffs of the Cook County Hospital and St. Joseph Hospital, where he died Oct. 17, aged 60, of acute myocardial infarction.

Jameson, Louis Blair ⊕ Medford, N. J.; Syracuse University College of Medicine, Syracuse, 1909; died in Elizabeth Aug. 2, aged 70, of injuries received in an automobile accident.

Johnson, David Powell, Chicago; Rush Medical College, Chicago, 1902; died Sept. 30, aged 86.

Meuser, Courtland Burgett, Ashland, Ohio; Starling-Ohio Medical College, Columbus, 1912; member of the Ohio State Medical Association; died Sept. 12, aged 70, of yellow atrophy of the liver and infectious hepatitis.

Meyer, Julian Erdreich ⊕ Columbus, Neb.; Jefferson Medical College of Philadelphia, 1917; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; newly installed president of the Nebraska Heart Association, of which he was a trustee from the time it was founded; on the staffs of the Lutheran Hospital and St. Mary Hospital; died Oct. 5, aged 62, of coronary occlusion.

Nadolny, Chester John, Cheektowaga, N. Y.; University of Buffalo School of Medicine, Buffalo, 1926; member of the Medical Society of the State of New York; served as health officer; on the staff of the Millard Fillmore Hospital in Buffalo, where he died Aug. 31, aged 54, of hemorrhage from ruptured esophageal varices and Laennec's cirrhosis.

Naugle, Johnson Edward ⊕ Sterling, Colo.; University of Colorado School of Medicine, Denver, 1910; on the staffs of the Logan County and St. Benedict hospitals; died June 16, aged 71, of coronary disease.

Ober, Bert Frank ⊕ Latrobe, Pa.; Medico-Chirurgical College of Philadelphia, 1906; for many years secretary-treasurer of the Latrobe Academy of Medicine; veteran of World War I; served as secretary of the staff of the Latrobe Hospital, where he died Sept. 27, aged 82, of congestive heart disease.

Quinn, Thomas, Napoleon, Ohio; Toledo Medical College, Toledo, 1909; died Sept. 2, aged 70.

Remley, Arthur Roscoe, Richmond, Mo.; St. Louis University School of Medicine, St. Louis, 1908; died Aug. 27, aged 75.

Sandholdt, John Peter, Moss Landing, Calif.; University of California School of Medicine, San Francisco, 1904; formerly practiced in Monterey, where he was city councilman and mayor; died in Monterey Sept. 24, aged 76, of intestinal obstruction.

Schiffbauer, Hans E. ⊕ Los Angeles; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, Chicago, 1907; associate clinical professor of surgery at the University of Southern California School of Medicine; member of the founders' group of the American Board of Surgery; fellow of the American College of Surgeons; served on the staffs of the California Hospital and the Los Angeles County Hospital; died Sept. 17, aged 73, of heart disease.

Sevenman, George William, San Mateo, Calif.; Cooper Medical College, San Francisco, 1894; an associate member of the American Medical Association; on the staff of the Mills Memorial Hospital; died Aug. 30, aged 82, of myocardial degeneration.

Vanzant, Frances Ralston, Houston, Texas; University of Texas School of Medicine, Galveston, 1926; member of the American Gastro-Enterological Association; fellow of the American College of Physicians; formerly secretary of the Harris County Medical Society; died in the Methodist Hospital Aug. 27, aged 54, of septicemia.

Vernon, Frank Atherton ⊕ Pikeville, Ky.; Medical College of Georgia, Augusta, 1935; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; veteran of World War II; on the staff of the Methodist Hospital; died Sept. 9, aged 46, of injuries received in an automobile accident.

Vixie, Loren Oliver ⊕ Monterey Park, Calif.; College of Medical Evangelists, Loma Linda and Los Angeles, 1944; died May 5, aged 38.

Wahle, Henry, Oakland, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, Chicago, 1897; an associate member of the American Medical Association; died in the Providence Hospital July 22, aged 86, of heart disease due to coronary sclerosis.

Walborn, Kenneth Boone ⊕ Fort Worth, Texas; Baylor University College of Medicine, Dallas, 1937; member of the American Academy of General Practice; veteran of World War II; died Sept. 6, aged 45.

FOREIGN LETTERS

AUSTRIA

Reactions of the Infant in the Neonatal Period.—At the meeting of the Society for Pediatrics in Vienna on June 26, Dr. H. Lehndorf stated that a change in the functions of all organs in the newborn infant takes place in the first few days of life. The clinical manifestations that occur unnoticed and without disturbances of the state of health are called reactions of defense; those that occur with symptoms of sickness are called reactions of alarm. In the adaptation phase, hormonal crises are caused by the effort of the newborn infant to be freed from substances transmitted from the mother through the placenta. The most important phenomenon in this phase is the biological allergy of the newborn baby, characterized by such transitory manifestations as erythema, edema, hydrocele, fever, and intestinal disturbances. The hypothesis is proposed that the fetus, which in utero is sensitized by the heterogeneous serum of the mother, during delivery again comes into intimate contact with the maternal blood, thus making for a second injection. This will, after an appropriate interval, produce allergic reactions. The concept of a changed blood morphology in the period of adaptation leads to a better understanding of the phenomena associated with this period. This is shown in the process of erythropoiesis. The elimination of the macrocytes and the creation of a generation of normocytes means a daily change of 20 billion erythrocytes. In addition there is also the decreased value of pleocytosis. The physiological anemia of the newborn infant is regulated by a complicated mechanism, a disturbance of which by shock or allergy will intensify hemolysis and the temporary inhibition of hematopoiesis and will produce the condition of anemia neonatorum transitoria. A physiological neutropenia and rarely a pathological transitory granulocytopenia have been observed in the leukocytopoietic system. A physiological thrombopenia in the first week of life and melena neonatorum have also been observed.

AFRICA

Symposiums on Cancer.—At a symposium on hepatic cancer and related disorders held in August at Makerere College Medical School, Kampala, Uganda, evidence of the high incidence of primary hepatic cancer in native Africans was presented. The incidence varied in different locations, the regions about Dakar, French West Africa, and Lourenco Marques, Mozambique, showing the highest levels. The disease occurs chiefly in men between the ages of 20 and 40, and it runs a rapid course. The gross and microscopic types resemble those seen in Europe and America except that their proportions may be different. The causes are not apparent, but some form of hepatic cirrhosis is usually present in patients with this type of cancer. Although the geographical areas having a high incidence of hepatic cancer also have a high incidence of malnutrition, including cases of kwashiorkor, it was the consensus that the patient with kwashiorkor, who often has an enlarged fatty liver, does not usually have a cirrhotic liver later. Other possible etiological factors were liver parasites, viral hepatitis, and hepatotoxic agents in food or drink.

A symposium on cancer in the native African followed in September at the Louvanian University of Leopoldville in the Belgian Congo. The site distribution of primary cancers in native Africans appears to be different from that in natives of Asia, America, and Europe. Among the tumors that are more frequent in Africa are carcinomas of the salivary glands, liver, and skin (especially the skin of the legs in relation to tropical ulcers), multiple hemorrhagic hemangioma of Kaposi, and reticulum cell tumors. Gastric, pulmonary, and colonic cancers seem to be relatively less frequent. There is some geographical difference in the incidence of various cancers within Africa, and the distribution is different from that found in the American Negro. For example, the great frequency of multiple hemorrhagic hemangioma of Kaposi reported in Uganda and the Congo is not seen in the Senegal at Dakar or in the United States. The participants in the symposium recognized the rich opportunities for studying etiological factors in cancer in this African material and the need for additional data. They recommended that a center be established in Africa for the accumulation and study of this material. A third group of visits and meetings followed immediately at the School of Medicine at Dakar, French West Africa, and included a visit to Pasteur Institute and the Nutrition Study Center. The members of the symposiums from the United States were Drs. A. Cantarow (Philadelphia), H. F. Dorn (Bethesda, Md.), W. S. Hartroft (St. Louis), P. E. Steiner (Chicago), H. L. Stewart (Bethesda), and A. Tannenbaum (Chicago).

DENMARK

Treatment of Lupus Erythematosus.—The claims made for quinacrine in the treatment of lupus erythematosus encouraged Nielsen and Christiansen (*Ugeskrift for læger*, Sept. 6, 1956) to give it an extensive trial. They report that, in a series of 97 patients, the disease was of the discoid type in 81 and of the erythematous type in 16. Most of the patients were treated in the hospital to facilitate the observation of any side-effects of the drug, but 41 were treated as outpatients. Two 100-mg. tablets were given daily for eight days; then 300 mg. was given daily until the skin turned definitely yellow; and then 100 to 200 mg. was given daily for a prolonged period, the smallest total dose being 1.6 gm. and the largest being 49.8 gm. (average 18 gm.). Broadly speaking the results were excellent in 33% and fair in 33%. The results were much the same whether inpatient or outpatient treatment was given, and the patient's sex and the duration of the disease also seemed not to influence the reaction to this treatment, but the prognosis improved markedly with the patient's age, for among the 16 patients over the age of 60, only one failed to get a good result. During an observation period of 12 months after the completion of the treatment, the relapse rate was about 80%. Side-effects were also troublesome, with 5 cases of dermatitis, 16 of dyspepsia, and 8 of hyperhidrosis traceable to the treatment. Because side-effects are reported as being less troublesome with the related chloroquine, this drug was tried. It is hoped that small doses given over a prolonged period may reduce the relapse rate. Freedom from the yellow skin produced by quinacrine is a further advantage of chloroquine. At present quinacrine may be said to be as good as, but not much better than, other drugs hitherto given for lupus erythematosus.

Thrombosis of the Pulmonary Artery.—Dr. K. Iversen undertook a retrospective study of 20 patients in whom thrombosis of the pulmonary artery was found after death (*Nordisk medicin*, Sept. 6, 1956). Most of the patients were elderly and had a variety of cardiopulmonary complaints. The clinical records were therefore bound to present a complex picture from which instructive elements had to be disentangled. The records belonged to a series of about 4,000 autopsy reports, so the incidence of thrombosis of the pulmonary artery in this series was 0.5%. The average age of the patients was 69 years, and in several the thrombi were evidently of long standing. In every case there was a record of dyspnea; dyspnea on exertion was the first symptom noted in 15 patients. All but one had been cyanosed. In 11 there was a history of pulmonary embolism at some earlier date. Most had had prolonged fever refractory to chemotherapeutic and antibiotic agents. Ten had been mentally confused. In 9 the onset of the thrombosis was acute, suggesting pulmonary embolism, and in the remaining 11 it was insidious, manifesting itself as cyanosis and dyspnea. Iversen suggests that a comparison of radiograms taken from time to time in the same patient may give a clue to the correct diagnosis, but he admits that in eight cases clinical evidence on which to found the diagnosis of thrombosis of the pulmonary artery during life was lacking. In such cases the thrombosis may be a terminal phenomenon.

Cancer Register.—Dr. Johannes Clemmesen has described the main activities of the Danish Cancer Register since its foundation in 1942 (*Nordisk medicin*, Oct. 4, 1956). Its task was to collect on a voluntary basis reports on cancer cases from all the hospitals in Denmark and to correlate these reports with the country's death certificates. Cooperation has been assured with the University Genetics Institute in order to facilitate the investigations

---

The items in these letters are contributed by regular correspondents in the various foreign countries.

conducted by the register into the influence of heredity on the development of cancer. It has found that heredity does have a certain but limited influence on the development of cancer of the breast. In cooperation with the State Serum Institute, at which a syphilitic register is kept, it was shown that the incidence of cancer of the cervix is abnormally high among prostitutes. The cancer register has also collected data showing that the incidence of carcinoma of the lungs is high in men in Copenhagen, where it was noted for the first time that the lung cancer rate rose as the social status fell. It is calculated that by 1990 the lung cancer rate for men in Copenhagen will be the same as that for all forms of cancer in 1950.

The Prognosis for Patients with Hypertension.—In 1946, Dr. Poul Bechgaard published a report on 1,038 patients with high blood pressure. Since then he has kept in touch with these patients. In *Nordisk medicin* for Sept. 9, 1956, he brought his observations up to date, with a follow-up period of 16 to 22 years. Using the crude death rate in Denmark as a base line (100%) and after excluding patients with renal disease and those who had some fatal disease, such as cancer, at the first examination, he found that the death rate was 238% for his male and 133% for his female patients. With the comparatively good prognosis for women, Bechgaard doubts if it is necessary to enforce strict measures on women with a systolic pressure under 200.

UNITED KINGDOM

Synthetic Detergents.—In 1953 the Minister of Housing and Local Government set up a committee to examine the effects of the increasing use of synthetic detergents. In its report, now published, the committee states that the incidence of skin trouble attributable to synthetic detergents is no higher than that previously due to the use of soap products, alkalies, and allied preparations. Inquiries made by the British Launderers' Research Association have revealed that dermatitis is rare among commercial laundry workers and that no significant increase has occurred since modern synthetic detergents were introduced. Similar investigations made by the Ministry of Health show that among the general population there has been some incidence of cases of dermatitis. Many of them may have been due to the use of unnecessarily strong detergent solutions. In 1951, of just under 10,000 new patients seen at the skin departments of a London and of a provincial teaching hospital, only 143 were suffering from dermatitis attributed to the use of synthetic detergents. The committee states that it has no reason to believe that there has been any increase in incidence since that time.

The manufacturers have reached the same conclusion, based on the results of inquiries among customers and on observation of the incidence of skin irritation among their own employees who have frequent and prolonged occupational contact with synthetic detergents. Users are advised to avoid making up unnecessarily strong solutions and, in any event, to rinse and dry their hands after using these detergents. People with unusually sensitive skins should choose the product best suited to themselves and should continue to use gloves, hand creams, and lotions.

The problem of acute poisoning is not considered serious. The only known case was in the United States, and in this instance a cationic detergent was involved. Most of the synthetic detergents used in England are based on anionic surface agents, and the committee has no evidence to show that these or the "builders" usually incorporated with them would, if swallowed by mistake, have serious effects. The problem of chronic poisoning is more important, as it derives from eating or drinking from crockery imperfectly rinsed after being washed in synthetic detergent solutions or from the drinking water from rivers polluted by sewage effluents containing detergents. Reference is made to an experiment with five commonly used synthetic detergents in which cups were washed in the normal way and drained without rinsing. Sufficient deposits of the detergent remained on the inner surfaces to produce, when the cups were refilled with tap water, concentrations ranging from less than 0.2 to 1.0 ppm of surface-active material. When the cups were rinsed after washing, the concentrations were less than 0.2 ppm—a concentration no greater than that already present in some tap waters before synthetic detergents came into widespread use.

Reference is also made to an investigator who took 1 gm. of sodium alkyl sulfate daily for eight weeks and who also gave, for seven months, 0.2 gm. every two hours in the daytime to a series of patients with gastric ulcer. In neither case was any ill-effect observed. No evidence was found to indicate that anionic or nonionic surface-active agents are harmful in this respect, but observations should be continued for long periods before a final conclusion is reached. Because of the widespread use of synthetic detergents, domestic sewage now contains complex compounds that are not completely destroyed during the treatment of sewage and water. Since the problem of dealing effectively with current synthetic detergents in sewage is considered almost unsolvable, it is essential that the manufacturers investigate the feasibility of replacing the present common types of household synthetic detergents with products of similar efficiency but based on surface-active agents less resistant to known methods of sewage treatment than those used at present. The committee is divided on the question of whether the public interest is sufficiently safeguarded while the recommended research is being carried out.

Emulsifying and Stabilizing Agents.—The Food Standards Committee of the Ministry of Agriculture, Fisheries and Food recommends that the use of emulsifying and stabilizing agents should be subject to statutory regulations and that the control of such agents can best be secured by specifying the substances that may be used. Those agents that are natural constituents of certain foods or are already common ingredients of food apart from their use as emulsifying and stabilizing agents need not be regulated. Apart from these, those recommended for inclusion on an approved list are as follows: superglycerinated fats, synthetic lecithin, propylene glycol alginate, propylene glycol stearate, methyl cellulose, methyl ethyl cellulose, sodium carboxymethyl cellulose, stearyl tartrate, diacetyl tartaric acid esters of superglycerinated fats, monostearin sodium sulfoacetate, and sorbitan esters of fatty acids. The addition of emulsifying and stabilizing agents to milk should not be allowed. Of the approved substances, superglycerinated fats and stearyl tartrate should be allowed in bread. The existing prohibition on the use of thickening substances in cream should be extended to cover reconstituted cream. It is not necessary or practicable to specify limits to the amount of an approved emulsifying or stabilizing agent that may be present in food, but the amount used should always be the smallest quantity consistent with the best commercial practice. Specifications of purity for the approved substances should be drawn up in order to ensure that they are of a high standard of purity when used in food.

Cost of the Welfare State.—At the end of 1955, the Ministry of Pensions and National Insurance was paying war pensions to 870,000 persons; family allowances to 3,250,000 families, consisting of about 8,250,000 children; retirement pensions to 4,500,000; widows' benefits and guardians' allowances to 470,000; and industrial disability pensions to about 130,000. During 1955, new claims for sickness benefits totaled nearly 8 million, for unemployment benefits over 2,250,000, and for industrial injury benefits over 830,000. The combined cost of these and other social benefits being paid by the Ministry of Pensions and National Insurance was at the rate of about 2.38 billion dollars a year. These are some of the facts presented in the annual report of the ministry for 1955. New claims for sickness benefits in 1955 totaled just over 7,900,000, at a cost of over 236 million dollars. It is estimated that 746,000 maternity grants were awarded and that in the same period 287,000 home confinement grants and 196,000 maternity allowances were awarded—at a cost of over 36 million dollars. Prosecutions for alleged traffic in used National Insurance stamps and other misuse of such stamps rose from 243 in 1954 to 320 in 1955. Criminal proceedings for failure to pay contributions and for allied offenses totaled 4,662. Legal proceedings were taken by the minister against 1,014 persons for offenses connected with improperly obtaining benefits; there were convictions in 976 cases.

Alcohol and Body Build.—Evidence suggesting that fat people have a special taste for alcohol is presented by R. W. Parnell (*Internation. J. Alcohol* 1:127, 1955). His conclusions are based on the findings in three different groups. The first group was composed of 265 male Oxford University students about whose drinking habits inquiry was made at the time of routine health examination. Their average age was 22. A correlation of their drinking habits and the findings on somatotyping showed that 25% of the endomorphs took alcohol regularly as compared with less than 5% of the linear ectomorphs. Dominantly muscular men (mesomorphs) occupied an intermediate position. At the age of

22, young men's habits are barely established, but it is reasonably certain that alcohol consumption will not have altered their physique to any material extent. The same trend in drinking was found among 92 male patients, aged 16 to 65 years, in a mental hospital. The third group was composed of 200 juvenile delinquents, in whom the general level of heavy drinking was substantially higher than among the students and mental hospital patients, but the highest proportion of heavy drinkers in this group was also found among the endomorphs.

Deaths due to Anesthesia.—For the first time the annual report of the chief medical officer of the Ministry of Health gives the number of deaths occurring as a result of the administration of anesthetics. There were 562 deaths associated with anesthesia, or about 0.1% of all deaths occurring in the population. In 1949 a plan was initiated by the Association of Anesthetists of Great Britain and Ireland for the reporting of deaths due to anesthesia. A committee was set up to consider such deaths, and it has now issued its report on the first 1,000 reports collected (*Anæsthesia* 2:194, 1956). In almost 600 of the cases, death was associated entirely, or to a large extent, with the administration of an anesthetic. The commonest single cause of death was the inhalation of vomitus. This occurred more often in labor than in surgical operations. In obstetric cases requiring operative treatment, anesthesia has become the commonest cause of maternal death. The report also reveals the frequency of fatalities after the intravenous use of barbiturates. The next commonest cause after death due to inhalation of vomitus is death during the immediate postoperative period due to respiratory obstruction or depression of respiration. Other causes of death listed are endotracheal anesthesia, convulsions, the use of antidotes and analeptics, spinal anesthesia, and deliberate induction of hypotension to minimize bleeding. Lack of skill, inadequate equipment, and insufficient medical or nursing supervision are responsible for many of the deaths. Sometimes in the immediate postoperative period patients are left without efficient suction in the care of a student nurse. Some patients are given powerful drugs without the physician's full appreciation of their effects. Ultimately the prevention of deaths resulting from the administration of anesthetics will depend on better training of anesthetists and nurses.

Blood Groups, Pernicious Anemia, and Duodenal Ulcer.—An editorial in the *British Medical Journal* (2:723, 1956) states that the collection of data from a number of centers shows fairly conclusively that pernicious anemia is commoner in persons of blood group A than in those of blood group O and also perhaps, though the numbers are small, than in those of blood group B. The greater incidence in group A appears in both sexes. An analysis of data, by Dr. C. A. Clarke and co-workers (*Brit. M. J.* 2:725, 1956), from 293 blood relatives with a history of duodenal ulcer gave no evidence to support the hypothesis that a person with blood group O is more likely to have a duodenal ulcer than are his blood relations with blood group A, B, or AB. It will also be a task for the future to ascertain whether the secretor phenomenon is likewise involved in other diseases known to be related to the ABO blood groups, particularly such diseases as carcinoma of the stomach and pernicious anemia. No causal relationship, whether of blood group or of secretion, has been established with any of the diseases mentioned, but, if and when such causal relations become established, it will become a matter of more than theoretical interest to investigate in detail the biochemical mechanism whereby the blood-group substances tend to protect or to damage the intestinal wall or the other tissues of the body. If, as appears likely, many diseases have an incidence that varies according to blood group and if the relation is a causal one, the cumulative natural selective effect on the blood groups is likely to be great. This may be the main reason for the different blood group frequencies found in different populations.

The Old Should Stay at Work.—At the annual meeting of the Association of Industrial Medical Officers, Dr. Andrew Meiklejohn, of Glasgow University, said that planning would soon be one of the major causes of ill-health among workers and others. Recommending continued employment after normal retiring age, he said the decision must be made by the person concerned. "Heaven forbid that we should get any more planning of the worker." Aside from the need for the production put forth by older workers, physicians should stress the fact that the real importance of the continued employment of the older workman is for his own sanity and general well-being. There is no health—physical, mental, social, or moral—in idleness, and idleness is what enforced retirement means for most unskilled laborers in industrial areas. Prof. Sven Forssman, medical adviser to the Swedish Employers' Federation, pointed out that with mechanization heavy work was disappearing. This gave a better chance to the older worker, who, moreover, could compensate for reduced physical strength by experience. A longer lunch period, with a corresponding wage reduction, has been tried with success in some industries.

The Ring Around the Bathtub.—Bacteriological cultures of 20 deposits taken at random by J. A. Boycott from the greasy waterline left after use on the bathtub in the women's ward of a hospital showed viable bacteria in all. These included coliform bacilli, Micrococcus pyogenes var. aureus, Streptococcus faecalis, and species of Neisseria (*Lancet* 2:678, 1956). An investigation was therefore carried out for the best practical method of cleaning bathtubs and basins after use. The following method is recommended, as it makes preliminary cleaning unnecessary and appears to be effective. Water, as hot as can be borne by the bare hand, is run into the tub to between a twentieth and a tenth of its effective content (1 to 2 gal.). To this is added 15 cc. of an approved hypochlorite and detergent sufficient for cleaning purposes. Because some detergents cause a release of chlorine, the hypochlorite and detergent should not be mixed before use. The tub is then washed thoroughly with a clean cloth used for this purpose only and the water allowed to drain out. Subsequent washing with tap water is unnecessary unless there is gross dirt left loose in the tub or unless an excess of detergent has made the tub slippery.

Prefrontal Leukotomy.—Elithorn and Slater in the *British Medical Journal* (2:739, 1956) say that recent correspondence in the *Lancet* and the *British Medical Journal* has shown that there are still widely diverging views on the value of leukotomy in the treatment of mental disorders. Of 103 patients, 66 were glad to have had the operation, 14 regretted it, and 23 were neither glad nor sorry that they had had the operation. The views of 93 relatives were also obtained: 72 thought the patient was better off, 11 thought the patient worse, and 10 thought it had made little difference. Unwelcome changes were reported by 43 patients and 51 relatives. A good result was reported much more often with a standard than with a modified operation. On the other hand, the incidence of bad effects was only slightly higher with the standard operation. It is emphasized that, whoever makes it, the determination of the value of a leukotomy to the patient is subjective.

X-Ray Hazards from TV Apparatus.—There is little danger to the public from x-rays emitted by cathode-ray tubes used in television sets, according to L. B. Bourne (*Lancet* 2:510, 1956). This conclusion is based on the findings in an investigation in which nine men and one woman were exposed for one working week to cathode-ray tubes subjected to voltages up to 20 kv. and monitored for irradiation from x-rays and cathode-ray tubes. In all the tests the results were below the tolerance level specified by the International Commission on Radiological Protection. This safety of television sets is due to the adequate safety standards incorporated in such apparatus. It may, however, become necessary to adopt new standards of protection if changes are made in television receiving equipment.

Candida Organisms in Sputum Specimens.—In order to determine the incidence of Candida species in routine sputum specimens Armstrong and Hall (*Month. Bull. Min. Health* 15:220, 1956) examined 307 specimens: 218 from nine chest clinics, 87 from four sanatoriums and one hospital for infectious diseases, and 2 from general practice. Yeasts were isolated from 195 specimens, or 63.5%. Of the 195 patients whose sputum yielded yeasts, 86 were also known to be excreting tubercle bacilli. All the 12 strains of Candida albicans that were inoculated subcutaneously into guinea pigs proved to be virulent. Since no particular precautions were taken in collecting the specimens, the mouth must be considered the source of some of the strains of yeasts isolated

CORRESPONDENCE

NEUROLOGICAL ILLNESS FOLLOWING POLIOMYELITIS VACCINATION

To the Editor:—The Poliomyelitis Surveillance Unit of the Communicable Disease Center, U. S. Public Health Service, has, since its inauguration in May, 1955, systematically collected information from all states on all aspects of field experience with Salk vaccine. This information is compiled in a weekly or bimonthly mimeographed report that is distributed to health departments, epidemiologists, clinicians, laboratory workers, and others interested in this field.

As one aspect of our national poliomyelitis surveillance program, we have collected data on a number of cases of neurological reactions following poliomyelitis vaccination. These were most recently summarized in our report no. 88. The neurological reactions following vaccination have been diverse in their manifestations. In the group included in report no. 88 there was only one case of myelitis. Since that report we have received several more reports of neurological illnesses in recently vaccinated individuals. Only one of these was a case of transverse myelitis. Both of the cases of transverse myelitis that have been reported to us have occurred in young children.

It is difficult to reach any final evaluation of these reports. However, since over 90 million inoculations of poliomyelitis vaccine have been given since May, 1955, it would be expected that a number of cases of neurological and other types of illness would occur by coincidence in recently vaccinated individuals. The relatively small number of possible complications of this nature combined with their diversity, and in face of the millions of inoculations given, lead us to believe at the present time that there is probably no causal association with the vaccine.

Our channels of reporting for various aspects of our program are primarily through state and local health departments. Since the health departments have no routine method of receiving reports of such peculiar reactions to vaccine, it is probable that we have not heard of all incidents of this type. It would be of great value to us if it could be noted that the Public Health Service is attempting to collect these data on a nationwide basis. We would be most interested in receiving reports of this kind, and these should be addressed to me at the address given below. Practitioners might also be urged to report such instances to their local or state health departments, which would then forward them to us. I would also be happy to answer any queries concerning these cases that are directed to us. Anything The Journal can do along this line to stimulate a more complete reporting on these atypical situations would be a value to us and would be highly appreciated.

SOCIAL SECURITY

To the Editor:—I should like to point out two errors in the article by Webster and Coffey, "Social Insecurity—The Trap Awaiting the Young M.D.," which appeared in the Sept. 15, 1956, issue of The Journal, page 231. It is stated "you cannot collect both survivors' benefits and retirement benefits. It's one or the other." This is, of course, true. However, no young physician can know which type of benefit he will need, whether he will survive long enough to retire, or whether he will die prematurely. Social security takes care of either eventuality for the single premium. Therefore, the cost of social security should be compared with the cost of commercial survivors' benefits plus retirement benefits, rather than with the cost of each individually, as was done in this article. It is stated "We believe your chances of retiring are less than one in seven . . . let us look for costs of a private [retirement] plan that would pay benefits equaling one-seventh of . . . social security . . . benefits." The cost of such private insurance is naturally found to be lower than that of social security. If I will need such and such a monthly income on which to retire, I will not be able to live on the fraction of that amount determined by the likelihood of my need for it. By such reasoning, my home, which is worth $20,000, should be insured against fire for only $200, since the chance of a house in my community catching fire is only one in a hundred.

Ira Leo Schamberg, M.D.
7852 Montgomery Ave.
Elkins Park, Pa.

To the Editor:—The issues of The Journal for Sept. 15 and 22, 1956 (pages 231, and 426, respectively), contain a two-part article on social security written by two physicians. The subject of social security is, indeed, pertinent to all physicians in America today. This is so because of a train of events that has led to a situation where we physicians are now the only group of workers in the United States not covered by this program. When one considers the number of physicians compared to the total population, we form a small fraction, and a searching reappraisal of our position might be in order. In making such a reappraisal, some considerations to bear in mind before arriving at a conclusion are as follows: There is no move afoot in either major political party to abolish the social security system; both parties have outlined plans to broaden and strengthen the program. The social security system is underwritten by the United States government, and so every United States citizen is, in turn, an underwriter. Since we physicians are also citizens, we are in a position of underwriting a program from which we derive no benefit. The social security program came into being as a result of legislation. However, the operating methods and details were set up by an advisory committee of citizens, and such a committee has continued to function in an advisory capacity. From the beginning, this committee has included successful and well-recognized executives from the insurance industry. When the annual committee reports of the county medical society are read, one hears, among others, the report of the welfare committee. When this report is read, one learns that there are fellow physicians living in retirement and survivors of deceased colleagues who could well use the benefits of a program such as the social security program offers, yet if they were getting this help they would not be getting charity. In conducting a referendum vote among the physicians as to whether they favor being taken into the social security program as a group, it is unrealistic to include the question as to whether the individual is in favor of inclusion on an optional basis. It is unrealistic to vote on such a question, because no such optional plan would be or could be considered by Congress. It is an inherent feature of the social security program, as it is set up, that it take in blocks of citizens on a compulsory basis. In recent years, doctors have been gaining experience in the operation of insurance plans through their local medical contract bureaus. This experience has taught us what professional insurance underwriters already knew, viz., that, in writing a group insurance contract, the larger the percentage of the group that can be included, the better will be the experience, and thus the lower the premium.

To the Editor:—"Social In-Security—The Trap Awaiting the Young M.D." by Webster and Coffey in the Sept. 15 issue of The Journal, page 231, is a very interesting and provocative article. However, there are a couple of questions and circumstances the authors do not cover. For example, they omit mention of the credit allowed for military service. There are more than a few medical reservists who were called to active duty as much as 18 months before Pearl Harbor, served six years, and then another two during the Korean conflict. This equals eight years' maximum premiums under social security that the ex-service man receives gratis. Medical Economics, Inc., published a report of a survey of physicians in which the doctors, by a slight majority, did not favor compulsory social security legislation. However, among psychiatrists 64% favored the measure. More than 90% of psychiatrists are full-time or part-time government employees and, being "pension conscious," seek to supplement their retirement provisions. If ordinary insurance offers better and cheaper coverage, why have underwriters, accountants, economists, etc., not enlisted congressional support to repeal social security? Why did the legal profession become subscribers to social security only this year? Certainly somewhere there must be a shrewd attorney, particularly a tax expert, who could detect the same flaws and disadvantages as were picked up by Webster and Coffey.

James A. Brussel, M.D.
80-45 Winchester Blvd.
Queens Village 27, N. Y.

To the Editor:—Enclosed are two pamphlets on social security (Poirot, P. L.: *Social Security*, New York, the Foundation for Economic Education, Inc., 1954. Manion, C. E.: The Social Security Tax, reprinted from *Ideas on Liberty*, no. 3, November, 1955, New York, the Foundation for Economic Education, Inc.). I am forwarding them after seeing in The Journal the articles by Webster and Coffey entitled "Social In-Security—The Trap Awaiting the Young M.D." in the Sept. 15 and 22 issues, pages 231 and 426 respectively. They discuss thoroughly the economic aspects of social security. Would it not now be appropriate to point out some of the moral, constitutional, and basic Americanism aspects of this monstrosity? These two articles may be reprinted without the necessity of applying for permission, which, in any event, would be freely given and which could aid physicians in making up their minds on this matter.

THE PHYSICIAN AND DISASTER

To the Editor:—Concerning the editorial "The Physician and Disaster" in the Nov. 3, 1956, issue of The Journal, page 977, I agree that local planning for disaster is the logical beginning. Coordination can then be achieved with state and region, rather than attempting to accomplish this from "above" or at national level. In Tulsa, Okla., each physician has a disaster assignment in the form of a certificate that he has received by mail, signed by the president of the county medical society and the civil defense medical director. Assignments were made for hospital duties, auxiliary hospital duties (in high schools), and field aid stations. There are no conflicting assignments. In this manner it is hoped that knowledge of a disaster situation will automatically cause each physician to proceed to his regular post of duty without undergoing the preliminary period of confusion that otherwise might ensue.

WHIPLASH INJURY

To the Editor:—The article by Gotten, "Survey of One Hundred Cases of Whiplash Injury After Settlement of Litigation" (*J. A. M. A.* 162:865 [Oct. 27] 1956) is the best approach to the problem that I have yet read. However, it is based only upon cases that were the subject of litigation and the conclusions are of necessity *post hoc, ergo propter hoc*. The figures can have no valid meaning until someone makes the same study, using the same questionnaire on the same number of cases of whiplash injury that have not been the subject of litigation. I strongly suspect that in such a control study the percentage recovery, length of disability, symptoms, and permanent disability will not be much different in the two series. Gotten's description of the mechanism of whiplash injury follows the common error, stating that when the victim's car is struck "from behind or from the side. His body is suddenly thrust in a position of acute flexion, followed by extension of head." This is exactly the reverse of the fact. Abbott, in his comment on Gotten's article (*J. A. M. A.* 162:917 [Oct. 27] 1956), is to be complemented for a diagram showing the correct mechanism. It is also correctly shown on page 48 of the excellent monograph "The Cervical Syndrome" by Ruth Jackson (Springfield, Ill, Charles C Thomas, Publisher, 1956), which should be required reading for everyone interested in the subject. I would also recommend the "Symposium on Whiplash Injuries" in the *International Record of Medicine and General Practice Clinics* for January, 1956, pages 1 through 30.

AMINOMETRADINE FOR TOXEMIA OF PREGNANCY

To the Editor:—I read with great interest the report of the Council on Pharmacy and Chemistry on aminometradine (Mictine) published on page 116 of the Sept. 8 issue of The Journal. Of particular interest to me was the sentence in the fourth paragraph, which reads as follows: "Sufficient valid evidence is lacking, however, of the drug's usefulness in toxemia of pregnancy or premenstrual tension." I have no quarrel about the usefulness of the drug in premenstrual tension, since I have had no experimental work to substantiate this claim. However, I would like to take exception to the statement about its usefulness in toxemia. My associates and I have carried out a substantial amount of research regarding the metabolic effects of aminometradine in toxemia of pregnancy. The first report of Voskian and myself was published in the July issue of the *Journal of Applied Physiology* (9:111, 1956). The data included in this paper show clearly that aminometradine produces a significant increase in water and electrolyte excretion, thereby improving the edema of both normal patients and patients with toxemia. No changes in the factors that control acid-base regulation were found. The effects of aminometradine were even more striking in patients with toxemia than in normally pregnant ones. At the present time, we are compiling the data obtained during the last two years from ambulatory pregnant patients who were given aminometradine for alternate periods Clinically and experimentally, the data indicate that aminometradine is an effective drug in toxemia and that the side-effects are minimal. Under these circumstances, it seems to me that the evidence toward its usefulness in toxemia is just as favorable as in cardiac or nephrotic edema.

HEART CATHETERIZATION

To the Editor:—The 1956 Nobel Prize for Medicine was awarded to one German and two American physicians for catheterization of the heart. According to news releases the experiments of Forssmann, the German scientist, date back to 1929. In this connection it may be of interest that catheterization of the heart was performed in 1908 by Fritz Bleichroeder, chief resident of the medical department of the Municipal Hospital Gitschenerstrasse in Berlin, Germany. Bleichroeder was in no way interested in the physiology or pathology of the heart. He was interested in the carbohydrate metabolism and wanted to obtain blood from the heart after 125 gm. of glucose was ingested. After numerous experiments on dogs without any accident, he successfully catheterized the heart of Joseph Portmann, laboratory technician at the hospital. Bleichroeder's approach to the heart was from the femoral vein. The procedure was done with a ureteral catheter. At the time of Bleichroeder's experiments I was intern at his department. When I finished my internship, Bleichroeder's investigations were not yet finished. I then became a ship's surgeon of the Hamburg American Line, and I don't know whether the procedure was ever published.

MISCELLANY

Following is a special report prepared by the Washington Office of the American Medical Association.—Ed.

FEDERAL MEDICAL-HEALTH SPENDING FOR FISCAL YEAR ENDING JUNE 30, 1957

This is our fourth annual report on the federal medical budget. To the extent we can make it so, it is a factual, objective study of how much the U. S. government is spending this fiscal year in all health and medical fields. We are dealing with money that has been appropriated and currently is available to be spent. This special report is based on the actual appropriations, and on information obtained directly from federal agencies and departments.

When talking in billions of dollars, it is often difficult to make the totals meaningful. However, here are some conclusions:

1. What the federal government is spending in health fields alone represents an average cost of $15.17 per man, woman, and child (Population, family-size, and employment figures from the census bureau). Incidentally, it is costing each of them $1.78 more this year than last.
2. If only wage-earners are considered, they will be paying on the average $38.72 each to finance the federal government's health-medical operations. That is $4.40 more than they paid last year.
3. The average family will be paying $54.61 this year for the U. S. government's health-medical activities.
4. Even in an over-all federal budget of 61.2 billion dollars, the total health cost is not insignificant. It is a billion dollars more than the cost of running the Commerce Department, half a billion more than all Agriculture Department expenses, and six times the Interior Department's budget.
5. Mostly because of spectacular increases for research, health programs of the Department of Health, Education, and Welfare this year will cost half again as much as they did last year.
6. For the first time since World War II, the medical costs of the Veterans Administration top the list, passing the Defense Department. A close third is the Department of Health, Education, and Welfare.

This report is based on spending alone. We do not undertake to evaluate the many individual programs. Obviously many of them are necessary just to maintain the United States' unsurpassed public health standards. Others undoubtedly will pay rich dividends in procedural and scientific discoveries. Some probably could be questioned. But the only purpose of this study is to show exactly what they cost.

MEDICAL-HEALTH BUDGETS OF FEDERAL DEPARTMENTS, AGENCIES, AND COMMISSIONS FOR THIS FISCAL YEAR

Summary of Budgets

Agency	Fiscal 1957	Fiscal 1956
Veterans Administration	$825,024,300	$790,185,800
Department of Defense	790,105,000	818,104,700
Department of Health, Education, and Welfare	772,661,800	526,935,400
Federal Civil Defense Administration	49,810,000	30,450,000
Atomic Energy Commission	31,525,000	27,700,000
International Cooperation Administration	29,310,000	25,441,000
Department of State	15,496,000	13,669,790
Federal Employees Health Program	10,000,000	6,000,000
National Science Foundation	8,000,000	5,000,000
Department of Labor	7,151,126	7,336,000
Department of Interior	6,138,205	5,770,000
Panama Canal Zone	6,055,300	5,702,900
Department of Treasury	3,511,700	2,900,000
Department of Justice	1,580,000	1,470,000
Federal Trade Commission	1,000,000	1,000,000
Department of Commerce	547,914	277,586
Civil Service Commission	386,000	382,600
National Advisory Committee to Selective Service	180,000	180,000
President's Committee for Handicapped	134,678	130,000
Health Resources Advisory Commission	90,000	101,000
Office of Attending Physician of Congress	12,145	......
Totals	$2,558,719,168	$2,268,826,576

VETERANS ADMINISTRATION
(This Year: $825,024,300—Last Year $790,185,800)

Inpatient Care in VA Hospitals..............................$619,614,000

(Last year: $615,869,000)

The VA's largest single medical appropriation covers inpatient care in 173 VA hospitals and provides for an average of 121,865 beds a day. At present the VA reports daily patient load at 111,540, just over 91% of capacity. The appropriation includes salaries of physicians and other personnel, medical rehabilitation of veterans, dietetic and nursing services, social services, and special services, such as recreation and transportation of veterans.

Outpatient Care $82,638,000

(Last year: $85,471,200)

The bulk of this appropriation is for outpatient care in about 100 VA clinics. The remainder is earmarked for fees to physicians ($7,738,000) and dentists ($8,415,000) under the home town care program.

Modernization and Replacement Construction........$51,635,000

(Last year: $30,000,000)

This amount is for work on existing units costing over $250,000 a project and equipment for new units. The money is available until expended. (See Major Alterations and Improvements item for smaller projects.)

Domiciliary Care $29,319,000

(Last year: $23,062,500)

Domiciliary care is being provided in 17 VA facilities for about 17,000 veterans who, while incapacitated for employment, are not in need of full hospital care. The VA also makes payments to 30 state homes in approximately 30 states with a daily patient load of around 9,000. Payments this fiscal year are estimated at $5,888,000 (under Public Law 613, 83rd Congress, federal contributions to these homes were raised from a maximum of $500 to $700 a year per patient).

Contract Hospitalization $13,967,000

(Last year: $15,237,300)

This appropriation finances an average daily patient load of 3,260 veterans in federal hospitals other than VA and in state and municipal hospitals. Patients in federal non-VA hospitals are estimated at 1,345 and in nonfederal hospitals, 1,915. Psychotic cases make up the largest single category of contract cases.

Medical Administration $7,300,000

(Last year: $7,422,000)

To operate the VA Department of Medicine and Surgery in the Washington central office and the seven area medical offices; included are salaries, travel, and like expenses.

Medical Research $10,990,300

(Last year: $ 6,381,600)

For research, mostly in VA hospitals. The breakdown: general medical and surgical research, $5,870,000; atomic medical research, $2,000,000; prosthetics testing, $990,300; neuropsychiatric, $1,250,000; tuberculosis, $780,000; and other, $100,000.

Major Alterations, Improvements, and Repairs..........$4,533,000

(Last year: $3,900,000)

For alterations, improvements and repairs to VA clinics and domiciliaries (costing less than $250,000 per project).

Supply Depot Operations..$1,628,000

(Last year: $1,642,200)

For maintaining and operating supply depots handling the purchase, shipping, and storage of medical supplies and equipment used by the Department of Medicine and Surgery.

Medical Education and Training...............................$1,400,000

(Last year: $1,200,000)

For VA training programs for physicians and other VA personnel, in medical specialties and auxiliary services.

Medical Care—Philippine Veterans...........................$2,000,000

(Last year: not reported)

Until 1960 the U. S. government will contribute for the care of Philippine veterans.

DEPARTMENT OF DEFENSE
(This Year: $790,105,000—Last Year: $818,104,500)

Army Medical Services*............................Approx. $290,000,000

(Last year: $300,000,000)

Air Force Medical Services*......................Approx. $223,000,000

(Last year: $286,000,000)

Naval Medical Services*...........................Approx. $277,000,000

(Last year: $232,000,000)

The estimated costs for the medical services of the Army, Air Force, and Navy include expenses normally associated with the operation of military hospitals and dispensaries, military and civilian salaries, medical supplies and equipment, utilities, communications, transportation, travel subsistence, maintenance and repair of buildings and grounds, expenses for construction, medical education and training, medical research, and preventive medicine.

Office, Assistant Secretary of Defense
(Health & Medical)....................................Approx. $105,000

(Last year: $104,500)

For salaries, travel and administration of this office, and for travel expenses and consultant fees for the Defense Department Civilian Health and Medical Advisory Council.

DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE
(This Year: $772,661,800—Last Year: $526,935,400)

Division of Hospital Facilities...............................$126,381,000

(Last year: $112,250,000)

This division administers the federal aspects of both the original and expanded Hill-Burton programs. The total appropriation is divided into the following four categories:

Hill-Burton Original Program...............................$102,800,000

(Last year: $ 88,800,000)

This appropriation, allotted to the states on the basis of population and per capita income, assists in the financing of new hospitals and related health facilities construction under the original Hill-Burton program. To date federal funds have partially financed approximately 2,869 projects, including nearly 132,096 hospital beds, and 636 public health centers, 18 state health laboratories and approximately 100 nurses homes and training facilities. To date federal contribution represents $762,000,000 and is matched by sponsors' funds amounting to $2,370,000,000.

Medical Facilities (Category Program)..................$21,000,000

(Last year: $21,000,000)

The total allotted to the states this year on a population-per capita income formula will assist in the financing of new construction under the 1954 amendments in four categories as follows: $6,500,000 for hospitals for the chronically ill and impaired; $6,500,000 for diagnostic centers, or diagnostic and treatment centers; $4,000,000 for nursing homes; and $4,000,000 for rehabilitation facilities. As under the original program, the federal share may range from one-third to two-thirds of the total project cost. As of July, 1956, there was approved a total of 204 projects divided among the four categories as follows: facilities for chronically ill, 42; diagnostic-treatment centers, 77; nursing homes, 42; and rehabilitation facilities, 43.

Hill-Burton Administrative Expenses.......................$1,381,000

(Last year: $1,250,000)

This appropriation is used for salaries and expenses for the hospital survey and construction program for Washington, D. C., and eight regional offices at the federal level.

Research $1,200,000

(Last year: $1,200,000)

Authorized in 1949 but not appropriated until 1955 was this item for research, experiments and demonstrations on utilization of hospital services, facilities, and resources. The bulk of the money is earmarked as grants to states, universities, hospitals, hospital associations, professional associations, and community organizations, and a small amount for direct research by the Public Health Service.

National Institutes of Health...................................$216,508,000

(Last year: $ 97,823,000

The total for the institutes is appropriated as follows:

National Cancer Institute..$48,432,000

(Last year: $24,828,00

About two-thirds of this appropriation is earmarked for gran to nonfederal individual investigators and private institutions f research and training and states receive $2,250,000 for canc control work. The balance is used for direct operations, salari supplies, and for this institute's share in the cost of operatin the Bethesda (Md.) Clinical Center and related auxiliary servic

National Heart Institute..$33,396,00

(Last year: $18,778,00

Grants to nonfederal individual investigators and public and private institutions for research and training take about two-thirds of the appropriation, and $2,125,000 is allocated to states for heart disease control. The remainder is for direct operations, such as salaries and supplies, and to support the Clinical Center.

Mental Health Institute...$35,197,000

(Last year: $18,001,000)

Approximately 60% of this appropriation is apportioned for research and training through grants to individual investigators and public and private institutions. The sum of $4,000,000 is allocated to the states for community mental health services. The remainder will support direct operations, such as salaries, expenses, and to help finance the Clinical Center and related auxiliary research services.

Arthritis and Metabolic Diseases Institute................$15,885,000

(Last year: $10,740,000)

---

*All figures are estimates because appropriations are not broken down into categories of medical expenditures. Anticipated reduction in the Department of Defense medical program during fiscal year 1957 is primarily attributable to more effective joint utilization of the facilities, fewer personnel assigned to operation, and a lower level of hospital and dispensary construction. Reductions, however, have been partially offset by an estimated expenditure of 41 million dollars during fiscal year 1957 for the Dependent Medical Care Program.

Grants to public and private investigators for research and training total $10,290,000. The remainder will go for direct operations, such as salaries and supplies and Clinical Center support.

Neurological Diseases and Blindness Institute..........$18,650,000

(Last year: $ 9,861,000)

Grants to public and private investigators and institutions for research and training total $14,280,000. The remainder is for direct operations, such as salaries and supplies and to support the Clinical Center.

Allergy and Infectious Diseases Institute................$13,299,000

(Last year: $ 7,580,000)

Research grants to public and private investigators for research and training amount to $8,182,000. The remainder finances direct research and other related services of the Institute.

Dental Health Institute...$6,026,000

(Last year: $2,136,000)

This appropriation is divided as follows: (*a*) for research and fellowships, $3,700,000, (*b*) direct research at Bethesda, $1,035,000, (*c*) review and approval of research grants and fellowships, $79,000; (*d*) administration, $100,000; (*e*) technical assistance to states, $824,500; and (*f*) coordination and development of dental resources, $287,500.

National Institutes of Health—General Funds........$12,122,000

(Last year: $ 5,899,000)

These funds are administered by the Division of Research Grants of the National Institutes of Health, with practically all funds being expended for research and training grants, with the exception of 1.7 million dollars for control of biologics (including polio vaccine), which activity is under the Division of Biologics Standards. The balance goes toward supporting fellowships and administrative expenses relating to grants.

NIH Planning and Construction...............................$33,501,000

(New category)

There is available for NIH for planning or construction of facilities $33,501,000 broken down as follows: $1,630,000, expansion of surgical NIH units, $200,000, planning for future construction for dental NIH research; $1,371,000, for animal quarters, NIH, $300,000, planning for office building, NIH; $30,000,000 grants for medical research facilities under Public Law 835.

Indian Health Activities...$48,075,300

(Last year: $38,840,000)

Under Public Law 568 (83rd Congress) PHS assumed responsibility for health of American Indians and natives of Alaska, which formerly was a function of Interior Department. The total is broken down as follows: hospital care in Indian hospitals, $23,001,400, contract patient care, $8,313,000, field health services, $5,940,600, program direction and management services, $2,058,300, and construction of hospitals, clinics and quarters, $8,762,000. The total appropriated for Indian health activities is $48,075,300, to which is added reimbursable items from other government agencies totaling $538,300.

Hospitals and Medical Care.......................................$40,969,700

(Last year: $34,326,000)

These funds are used for operational cost and maintenance of PHS hospitals and health services in caring for American seamen, Coast Guard and Public Health Service personnel and their dependents, Federal employees injured at work, leprosy patients, and narcotic addicts; includes studies in the development and coordination of nursing resources. It also includes $1,000,000 for grants to Hawaii for care of patients suffering from leprosy and $2,000,000 for nurse training grants. Not shown is approximately $800,000 additional income from reimbursable items from other federal agencies.

Poliomyelitis Vaccine Program..................................$23,600,000

(Last year: $30,000,000)

Public Law 411 extended last year's $30,000,000 poliomyelitis vaccine program. Additional appropriated funds amounting to $23,600,000 are available in addition to unexpended appropriations of last year to states for vaccination of children under 20 and pregnant women against poliomyelitis. The federal vaccination program is scheduled to expire on June 30, 1957.

Assistance to States—General....................................$17,591,000

(Last year: $18,160,000)

Grants totaling $12,000,000 will be available for apportionment to the states in support of state and local general public health activities. These grants must be matched one state dollar for every two federal dollars. Last year $4,500,000 was available for activities in administering the polio vaccination programs in the states. An additional $4,591,000 supports direct activities of the U. S. Public Health Service in providing technical assistance, consulting services to states, expenses of the National Office of Vital Statistics, international health activities, demonstrations, training activities, and operational expenses. An additional $1,000,000 will be available for grants to schools or direct traineeship awards to individuals for the training of professional public health personnel. In this program matching will be required.

Tuberculosis Control $6,660,000

(Last year: $6,000,000)

Grants to states for diagnostic and treatment clinics, mass case-finding, and follow-up services account for $4,500,000, all of which has to be matched equally by the states. The remainder is for direct operations of PHS.

Communicable Disease Control..................................$5,750,000

(Last year: $5,250,000)

The entire appropriation is used for direct activity of the PHS Communicable Disease Center at Atlanta, Ga., and its affiliated operations, including investigations in poliomyelitis. The center carries on studies in epidemiology, furnishes laboratory diagnostic services and sponsors special projects to assist states.

Sanitary Engineering Activities...................................$9,000,000

(Last year: $4,690,000)

This program is made up of seven activities as follows: air pollution, $2,740,000; water supply and water pollution control, $4,224,100; radiological health activities, $347,800; milk and food sanitation activities, $446,000; interstate carrier and general sanitation activities, $493,000; Sanitary Engineering Center research activities, $403,100; accident prevention, $51,000; and administration, $295,000.

Venereal Disease Control...$4,195,000

(Last year: $3,500,000)

Of the total, $1,700,000 goes for direct grants to states for venereal disease detection, treatment and control on a special need basis. The remainder is spent for technical assistance to the states, mostly to pay federal employees assigned to state health departments.

Foreign Quarantine Service...$3,315,000

(Last year: $3,000,000)

This service operates approximately 250 medical quarantine stations on borders of the United States. It also operates approximately 25 medical examination stations on foreign soil for the examination of aliens seeking visas to enter the United States. Inspections are made of all seagoing vessels and aircraft entering the United States.

Office of the Surgeon General..............................$3,892,000

(Last year: $2,762,000)

For administrative expenses of this office, including all housekeeping services, evaluation of public health needs, and personnel training. Included also is $700,000 for administration of the National Health Survey Act authorized by Public Law 652.

Water Pollution Control..$50,000,000

(New category)

Under a new law passed by Congress in 1956 (Public Law 660), the federal government will make grants for waste treatment plants.

National Library of Medicine......................................$1,376,000

(New category)

As a result of Public Law 941 enacted by Congress in 1956, the Army Medical Library has been renamed the National Library of Medicine and transferred to the Department of Health, Education, and Welfare. While it is contemplated that a new structure will be erected to house the library, only operational funds and planning money have been made available by Congress for this fiscal year. Operational funds for the nine months which remained in the fiscal year following the transfer of the library to HEW total $1,026,000. An appropriation of $350,000 was made for planning the construction of a new library building.

Alaska–Disease and Sanitation Investigations
and Control $1,185,000

(Last year: $1,125,000)

This appropriation will be divided as follows: $638,000 for grants to the territory for public health services and the remainder for research activities of the Arctic Health Research Center at Anchorage.

Alaska Mental Health Program..$25,000

(New category)

Authorized by Public Law 830, which calls for the construction of a mental health hospital in Alaska and federal funds for operation of a mental health program. The first appropriation is for initial planning.

Reimbursable Health Program for Other
Governmental Agencies $321,800

(Last year: $321,800)

This represents the cost of services expected to be advanced by Public Health Service to other governmental agencies for establishing and operating on-the-job clinics. As a total, however, it is misleading, as a substantial number of government agencies carry on their own health programs independent of PHS. PHS deals largely with Washington personnel, whereas 90% of the government's employees are located outside of Washington.

Social Security Administration..............................$161,183,000

(Last year: $125,796,600)

The total includes:

Bureau of Public Assistance (medical
payments) ....Approx. $100,000,000

(Last year: $ 90,000,000)

An estimated $265,000,000 of federal, state and local funds is expected to be paid for medical and health needs of public assistance recipients this fiscal year. The United States' share of this total is an estimated $100,000,000. This bureau operates under the Social Security Administration.

Disability Freeze Program ....Approx. $9,000,000

(New category)

Among the administrative expenses of the Old Age and Survivors Insurance program, is an item incurred by excusing disabled persons from paying OASI contributions without penalty in their retirement payments. This phase of the program is referred to as the "disability freeze" amendment to the Social Security Act. This year approximately $9,000,000 will be expended for employees' salaries, working materials, etc.

Permanent and Total Disability Payments..Approx. $11,000,000

(New category)

Under the 1956 amendments to the Social Security Act, persons over age 50 who become permanently and totally disabled may receive payments equal to retirement benefits as though they had reached age 65. This new program will take effect on July 1, 1957. This fiscal year, however, expenses will be incurred for "tooling up." These expenses will include recruiting of additional staff for field offices, training of staff, revising manual materials, negotiation of new agreements with state agencies for rehabilitation, and the furnishing of new materials for states to use, such as forms, etc.

Children's Bureau $41,183,000

(Last year: $35,796,600)
